are of longer duration than those making merely dots. The saving of time thus effected is of great importance, especially on long lines in which an appreciable amount of time is expended in the passage of the current. In long lines of submarine telegraphs, as will be noticed below, a greatly increased resistance is experienced in charging the wires with the electric current, and the impulses necessarily succeed each other with extreme slowness and diminution of force. The type wheel in the Hughes system is provided with 28 types; it is kept in rapid revolution during the whole time of operating, and is so perfect in its movement, that though the revolutions may be from 100 to 140 per minute, the variations of two machines at different stations do not exceed $\frac{1}{10}$ of a second in several hours' running. At the instant one of the 28 keys of the key-board, which is like that of the House telegraph, is depressed, the current entering the magnet at the distant station causes the strip of paper to be brought against the type opposite to it at the time, and receive the impression in ink while this is rapidly carried round with the wheel. The operator can send an average of two impulses with each revolution of the type wheel, thus making the capacity of the instrument full 200 letters or 40 words per minute, and the maximum is much above this. The regulators or governors of the clockwork which carries the type wheels at the different stations are of an entirely novel character. These are springs of the same musical tone, which consequently vibrate the same number of times per second, and which control by their vibrations the escapement of the apparatus. The power of the electric current required is reduced in a wonderful degree by the combination of the natural magnet and the electro-magnet, making only so much electricity necessary as will neutralize the magnetism in the natural magnet by causing magnetism of an opposite polarity to be created in the poles of the electro-magnet. This extreme delicacy, however, renders the telegraph liable to be interrupted by atmospheric electricity, such as is developed previous to and during the continuance of the aurora borealis. It is asserted that this instrument can work upon a longer line without the aid of repeaters than any other, and this with an extraordinarily low battery power.—In the winter of 1858 a new instrument was perfected by G. M. Phelps of Troy, combining the most valuable portions of both the House and Hughes patents, and which has been introduced with great success on nearly all the lines formerly using those inventions. This has appropriately been termed the "combination" instrument, and has the advantage of being able to work through a much longer circuit than the House machine, with a smaller battery, as well as of being much simpler in construction. The key-board and transmitting machinery of this instrument are precisely like those of Hughes, as is also the printing apparatus, with the excep-

tion of the electro-magnet, which is of the ordinary form, and operates upon the type wheel through the medium of compressed air as in the House machine. The vibrating spring used by Hughes as a governor is superseded in the combination instrument by a most ingenious electro-magnetic governor, the invention of Mr. Phelps. It consists of a hollow iron drum, geared to the transmitting cylinder and type wheel of the instrument and moving with them, but much faster. If the machinery has a tendency to revolve too rapidly, the increased centrifugal force, acting upon a detached section of the drum, actuates a series of levers inside, by which a spring is raised, closing the circuit of a local battery through an electro-magnet. A friction brake, which is applied to the revolving drum by the attraction of this magnet, instantly reduces the speed to the required limits, when the local circuit is again broken. The combination is considered to be the most perfect printing instrument yet produced.—Among the several telegraphs employed in England, those of the "Magnetic Telegraph Company" are worked by magneto-electricity, thus dispensing with voltaic batteries, the use of which involves much care and expense. The apparatus is remarkably compact, without clock-work or complicated movements such as are common in other telegraphs. Though used double with two sets of magnets, with a wire from each connecting with two needles upon the dial at the opposite station, the whole apparatus including the tablet or dial occupies but a few inches space, and is always ready for instant use, however long it may have remained inactive. The magnets, of horse-shoe form, about 12 in number for each set, are about 15 inches long and 1½ broad. They are laid one upon another in two piles near together, and fastened down to the table by screws. Opposite the ends of each pile, placed upon a rotating axis, is the soft iron armature, consisting of two cylinders wound around with long coils of fine copper wire covered with cotton. The wire of the two coils is connected together, and one end of each passes in a spiral through the axle to the platform upon which the apparatus rests. One end is thence carried into the earth, and the other goes to the electro-magnet of its own dial, thence to the distant station, and through the instrument there into the earth. The same arrangement is repeated with the other set. The axis of each armature extends toward the operator, and is provided with a crank handle by which each is turned to generate the electric current. The effect is seen in the movement of the two needles placed upon the dial over the magnets. It is asserted that this telegraph is worked with the greatest economy, that it cannot be disturbed by electric storms in the atmosphere, and that its average celerity has been found to be 27½ words per minute, with a maximum of 87½.—Telegraph wires are carried over the surface of the country supported upon poles standing 25 to 30

feet above the ground, and placed from 80 to 100 yards apart. If made of red cedar or locust and about 10 inches diameter at the base, they may in general be depended upon for 30 or 40 years; but some poles decay in 3 or 4 years. The durability of other woods may be increased by thoroughly coating them with coal tar. In Europe it is common to saturate the wood with some of the chemical preparations noticed in PRESERVATION OF WOOD. In crossing rivers, where, on account of the swiftness of the current or the danger of disturbance from drift wood, ice, or the anchors of vessels, an insulated wire could not safely rest upon the bottom, masts are erected on the opposite shores, sufficiently high for the wire suspended between them to be above the reach of the masts of boats and vessels that navigate the stream. The longest span in Europe is one of 1,700 feet over the Niemen river at Kovno, in Lithuania. In the United States there are many much longer crossings. That formerly used over the Hudson river at Fort Lee was of 2,700 feet; but the river is now crossed from the foot of 14th street to Hoboken by 6 sunken cables, each having 8 conductors. The Mississippi is crossed at St. Louis in two spans, one of 2,700 and one of 2,300 feet; and near Cape Girardeau, 2,980 feet, from a mast on the Illinois shore 210 feet high to one on the Missouri shore 205 feet high, from a base 110 feet above the water. The Ohio at Paducah is crossed in two spans, one of 2,400 and one of 3,720 feet. At the last named point, on the Kentucky side, the mast is 307 feet high above a bank 32 feet from the water; on the island in the river is a mast 205 feet high, and on the Illinois shore is one 215 feet high. Such masts require strong bracing to bear the strain of the wire with so long a leverage, and resist the action of the winds. The wire employed in these crossings is of iron known as No. 16, and weighs about 63 lbs. to the mile. Sunken cables are fast taking the place of all such river crossings. The ordinary telegraph poles require to be of sufficient strength to sustain a weight of over 400 lbs. suspended upon the wire between them, and at corners they should be still stronger. The following table represents the common numbers of iron wire used for this purpose and its strength, as plain wire, and also when coated with zinc, the figures representing in pounds the strain at which each kind broke. The American wire is stronger than the English, and about equal in this respect to the Swedish:

No.	Plain iron.	Zinc-coated.	No.	Plain iron.	Zinc-coated.
6	2,890	2,900	10	1,285	1,370
7	2,210	2,010	11	1,155	1,048
8	1,965	1,890	12	999	889
9	1,665	1,520	13	886	641

As, with batteries of the same intensity, the power of conducting currents of electricity increases with the superficial area of the conductor, large wires are to be preferred to smaller ones upon long circuits. In working direct, a distance of over 400 or 500 miles, the line is

usually divided at some intermediate point into two distinct circuits, which are connected by means of a "repeater." This operates as a double relay, so that if the circuit be broken on either side of the repeater, it will break the circuit on the other side also. The combined circuits can thus be operated from either end as if they were one continuous wire, while the current of each battery has to pass only half the distance between the terminal stations. A line can thus be extended indefinitely by interposing repeaters at proper intervals and dividing it into a number of separate circuits. Copper wire is a much better conductor than one of iron of the same size, and would carry the electric current from 5 to 6 times as far; but want of strength, and frequent breakage from its greater expansion and contraction by the changes of temperature, prevent its use except on important submarine lines.—Upon some telegraph lines in Europe and in Asia, the wires, instead of being supported upon poles, are buried beneath the ground. Their first cost is always heavy, and many of them have soon proved failures through imperfection in the insulation of the wires, and sometimes from settling in the ground. The wires are best insulated by coating them with gutta percha, and they are protected from injury by laying them in pipes of lead or of earthenware, or in wooden boxes preserved by saturating the wood with a solution of sulphate of copper or chloride of zinc. Some of these lines have worked perfectly well for many years, but when they fail it is a matter of great expense and difficulty to discover their defective points. The insulation of the wires upon the posts is a matter of much importance, and is not easily effected, for any non-conducting substance interposed between the wire and the post becomes a conductor when its surface is wet with rain. Glass knobs with grooves around them for securing the wire have been made of a great variety of forms, and secured to the posts, or to the cross bars where these are to carry several wires, by pins of wood or iron. A great improvement upon this is a glass cap exactly fitting over a wooden pin $1\frac{1}{4}$ inches in diameter, and having an outer covering of wood, saturated like the pin with coal tar and pitch, to which the wire is fastened, and which, projecting below and entirely covering the glass, keeps it dry and makes the insulation complete. Hard rubber insulators have been very extensively applied in the northern states during the past five years. The devices in use in different countries for this purpose are very numerous. In forests the wires should be allowed to pass loosely through the supports, so that in case of a tree falling upon them they need not be broken; but in an open country they are usually fastened to each post. The wires are tightly strained as they are set and secured to the posts; and after the work is completed they require to be frequently looked after by attendants designated repairers, who follow the line and connect the wires when

broken by drawing the ends together and soldering them. These men are often expert operators, and it is narrated of some of those employed in the United States, and familiar with the Morse system, that they can receive intelligible communications through the impressions made by the electric current upon the tongue when the two wires are placed one above and one beneath it.—In the extent of its telegraphic lines the United States has exceeded every other country. In 1860 it was estimated that there were over 50,000 m. in operation; and since that time the number has been largely increased by the completion of the line from St. Louis to San Francisco, which was opened Oct. 25, 1861, and thence to Oregon. In New York city a great number of lines are concentrated, and the following will convey some idea of the extent of the business carried on by the associated companies in their building situated at the corner of Broadway and Liberty street. The basement contains the "delivery" department and the supply department or storeroom, where all materials and instruments used on the lines are kept on hand to be used as required. On the first floor is the department for the reception of messages, in the rear of which is the operating room of the American company, a spacious apartment containing 25 instruments, each arranged on its own table. The wires enter at the rear of the room, and pass to a "switch," which is so arranged that any instrument in the room may at pleasure be instantly placed in connection with any line entering the office. From the switch wires are conducted separately to each instrument. On the second floor are rooms occupied by the president, secretary, and other principal officers of the company. The third floor contains the operating room of the New York and Buffalo and Erie lines. The rooms of the associated press are on the fourth, and the battery room on the fifth floor. In the latter room are some 375 cells of Grove's battery, from which all the lines are supplied with their electric current.—It is estimated that in Great Britain and Ireland there are 40,000 m. of telegraph; in Germany, 35,000; in France, 26,000; in Russia, 12,000; in Italy, 6,600; in Switzerland, 2,000; in Denmark and Sweden, 2,000; in Turkey and Greece, 500. In Australia it is believed there are about 1,000 m. completed, and in India over 5,000 m. controlled by the East India company. The Russians are engaged in extending a very important line from Moscow to the Pacific, which will thus connect eastern Asia with the countries of Europe, and eventually by Behring's straits with the American continent. This line was completed to Perm on the borders of Siberia, and thence over the Ural mountains to Omsk on the Irtysh, in 1861; thence it is to be continued to Tomsk, and S. E. to Irkutsk, the capital of Eastern Siberia. It will then cross the Altai mountains to Kiakhta on the Chinese frontier, and then to Cheta on the Amoor. It will then cross to Nertchinsk, to

which point it is to be completed in 1868. From Oroum or some other point on the Amoor one branch will extend down the river, and another toward the S. to a Russian port on the Japan sea. The route from the mouth of the Amoor toward the American continent may be by a short submarine cable to the island of Saghalien and the whole length of the island to its southern extremity, and by a submarine cable to the island of Yesso, and thence by a succession of cables and short land lines through the Koorile islands to the S. point of Kamchatka; thence along the E. coast by Petropavlovsk to a point opposite Behring's island. By another series of cables and land lines the telegraph will then be extended by the Aleutian islands to America. These islands are inhabited, and the line through them is doubtless much more practicable than by Behring's straits. The longest cable required will not, it is supposed, exceed 200 m. From Russian America to Oregon the intervening space is about 1,700 m., and on the Asiatic side from the straits to the mouth of the Amoor the distance is about 2,200 m. It is believed that the cost of making this connection, unless more serious difficulties are encountered with the savage tribes than is apprehended, will not exceed the cost of the Atlantic cable which was laid in 1858.—The applications of the telegraph have been extended to purposes never anticipated by those who have been most instrumental in establishing it. In 1852 Dr. William F. Channing and Moses G. Farmer of Boston devised a system of telegraphic fire alarms, which was adopted in the city of Boston. Five so called signal circuits were extended from the city hall to different parts of the city, and in connection with these were stationed 50 signal boxes attached to buildings at convenient points. The door of each box being opened, a crank is seen with directions for the number of times it is to be turned to convey to the central office the number of the station and district. From the central station 5 wires called alarm circuits connect with the different fire bells throughout the city, the hammers of which, run by weights, are set in action by the telegraph itself and strike the number of the district and station of the alarm. The electric current is excited by a magneto-electric machine which is set in motion by the pressure of the water with which the city is supplied, and the same power is employed to wind up the weights that move the bell hammers. The bells have been rung as an experiment from Portland through the telegraph wires extending to that place, and arrangements had been made just as the Atlantic cable ceased to work to have them set in operation from the telegraphic station in London. The fire alarm also affords an incidental protection to the city from lightning. Large metallic surfaces being placed near the wires at all the stations and connected with the ground, a stroke of lightning upon the wires will leap across to these conductors, and pass harmlessly

to the ground, while the artificial current possesses too little intensity ever to overcome the intervening space, and continues in the circuit. Similar arrangements are provided upon many telegraph lines. The fire alarm telegraph is also employed to designate the exact noon by a single stroke upon the bell of the Old South church, an exact chronometer being placed in the circuit and arranged so as to pass the current at 12 o'clock precisely. By a similar arrangement in London a large ball is made to drop exactly at 12 o'clock from a pole erected in the Strand by the action of a current from the royal observatory. The same thing is also done at Nelson's monument, Edinburgh. In Paris a cannon is fired upon a similar plan. Chronometers in observatories are also made to run synchronously with a standard instrument by means of the electric current connecting them with this.—The application of the telegraph to the determination of longitude has been described in the article *COAST SURVEY*, vol. v. p. 397.—Upon some railroads, as the Erie road especially, the telegraph is used with great advantage for regulating the running of trains from the different stations, and it is found that a single track by its aid may safely work up to the usual capacity of two tracks.—In numerous places telegraphs have been constructed for private purposes, as from the workshops to the offices of manufacturing establishments; and for government purposes from the halls of legislation to the printing offices, thus affording the greatest facilities for the immediate printing of important public documents, and of speeches while these are in course of delivery. A system of telegraphs for the use of large cities has been recently devised by Prof. Wheatstone, by which a company will lease the use of a small wire by the year to individuals. For distances not exceeding 20 m. a copper wire no larger than a cotton thread is sufficient. Numbers of these, insulated by being wound with thread, it is proposed to bring together into one cord, and suspend as many of these as may be required from strong iron wires passed in different directions through a city upon the houses. The latter, communicating with the ground at numerous points, will convey away all atmospheric discharges that might otherwise be troublesome.—The idea of a submarine telegraph appears to have been conceived by several of the earlier electricians. Don Francisco Salva is said to have proposed one as early as 1797 between Barcelona and Palma in the island of Majorca. Experiments were made in India by Dr. O'Shaughnessy in 1839 with this object, and he insulated his wires by covering them with tarred yarn, enclosing them in split rattan, and covering this again with tarred yarn. Prof. Wheatstone in 1840 gave it as his opinion before a committee of the house of commons that a submarine communication between England and France was practicable. Prof. Morse, on Oct. 18, 1842, laid a copper wire, insulated by means of a hempen

strand coated with tar, pitch, and India rubber, from Governor's island to the Battery in New York, and the next morning was beginning to receive communications through it, when the wire was caught in the anchor of a vessel getting under weigh, and being hauled on board was robbed of a considerable portion which the sailors carried away. It was to avoid the risk of disturbance that Prof. Morse entered upon those investigations which led to his discovery of a method of transmitting the current across a body of water by means of extending the wires a distance proportionate to the width along the banks on each side, and causing the poles to terminate each pair opposite each other in large metallic plates in the water. Mr. Samuel Colt laid a submarine cable in 1848 from Coney island and Fire island, at the mouth of New York harbor, up to the city, and operated it successfully. (See COLT, SAMUEL.) The first submarine telegraph wire laid in Europe was across the Rhine from Deutz to Cologne, a distance of only about half a mile; it was insulated with gutta percha, and laid by Lieut. Siemens of the royal Prussian artillery. This appears to have been the first application of gutta percha to this purpose, the substance about that time first beginning to attract attention. The grand attempts to connect the European with the American continent by laying a cable across the Atlantic, commenced in 1857 and perfected Aug. 5, 1858, have been noticed in the article FIELD, CREUS W. Before these were undertaken great encouragement was given to the enterprise by the successful experiments made on Oct. 9, 1856, in transmitting distinct signals at the rate of 210, 241, and even 270 per minute through a number of connected coils of wires insulated with gutta percha, and making a total length of about 2,000 m., increased to a virtual circuit of 2,800 m. by the interposition of fine wires at the joinings of the coils. The wires were excited through the magneto-electric coils of Mr. Whitehouse, and the signals were received upon the ordinary recording apparatus of Prof. Morse. But a great difference was afterward experienced in the working of the wires when submerged. Before the laying of the cable it was ascertained that insulated wires acquire a new character when submerged, and instead of transmitting the current as simple conductors, they are of the nature of the Leyden jar, the gutta percha corresponding to the glass, the inner wire to the interior coating, and the iron coating or the fluid surrounding the cable to the exterior conducting surface, and that consequently the cable must be charged throughout the entire length before any effect is produced. Among other interesting phenomena, it was observed that the voltaic current is not transmitted so rapidly through such a conductor as the magneto-electric current; that several distinct impulses may pass in succession at the same time, one after the other, through the wire within certain limits without interference; and that alternating positive and

negative currents are transmitted many times more rapidly than successive impulses of the same character. After being laid, the wires were first worked by the Ruhmkorff induction coils and a Smee's battery, and afterward with a Daniell battery; but the current was for the most part so weak as scarcely to work the most delicate relay, susceptible to an impulse that can hardly be perceived on the tongue. The effect was indicated at the Newfoundland station by the deflection of a delicate galvanometer, and at Valentia in Ireland by that of the reflecting galvanometer of Prof. William Thomson, the effect of which is to multiply the movement in a ray of light reflected from a mirror attached to a very delicate magnetic needle. This ray being thrown upon a surface at some distance, a movement of the needle, that is otherwise imperceptible, may be even measured upon a graduated scale. The transmitted current was, much of the time that the cable continued in action, so weak that every expedient of this kind was necessary to render the signals perceptible. From the first there appears to have been a defect in the part of the cable laid toward the Irish shore, and this caused a temporary interruption of the communications that passed between the ships, and excited much fear for the result of the enterprise until these were soon renewed; and it is generally believed that the very imperfect signals and variable conditions of the cable during the time that signals passed through it from Aug. 18 to Sept. 1 were attributable to this original defect, at least as the main cause. During this time 129 messages were sent from Valentia to Newfoundland, and 271 from Aug. 10 in the other direction. The number of words in the former direction were 1,474, and in the latter 2,885. The message from Queen Victoria to the president of the United States, consisting of 99 words, occupied in its receipt at Newfoundland 67 minutes. The rate of reception of messages at the two stations was however very variable, the signals being often unintelligible and requiring several repetitions. The retardation consequent upon the phenomena of induction, incident to the wire assuming the character of a Leyden jar, was considered by W. T. Henley, telegraph engineer, of London, so great that in the most perfect cable across the Atlantic no more than 4 words per minute under the most favorable circumstances could be transmitted on the plan of the dots and lines; but if a letter could be indicated by one or two signals, the rate of course would be proportionally increased. The feebleness of the current through the cable in consequence of any defect rendered its working liable to be interrupted by the natural currents of electricity in the earth, which by induction excite in an insulated wire currents moving in a contrary direction to their own, and overcome any artificial electricity of little force in the conductor. The changes in the natural currents from positive to negative and back again may be often mistaken for those

transmitted from the opposite station. With perfect insulation the natural currents would in general be overcome by the greater power of the battery. On the failure of the cable to communicate intelligible signals, every effort was made to ascertain the exact cause with a view of remedying the defect if possible. The most able electricians were sent to Valentia, and the most powerful batteries, as well as the great magneto-electric machine of Mr. Henley, were applied to test the condition of the cable. On Oct. 20, in the course of these trials, a communication was received at Valentia and imperfectly read as follows: "Two hundred and forty. t- k—— Daniells now in circuit." These were the last intelligible signals transmitted through the wires, and it afterward appeared that the full message was: "Two hundred and forty trays and seventy-two liquid Daniells now in circuit." The power thus employed was more than 1,000 times what would be required in an ordinarily well insulated conductor to give perfect signals to the mirror galvanometer; and the hopelessness of further attempts to transmit through the cable was apparent unless the faulty points could be repaired. The report of Mr. Henley of Sept. 30, 1858, to the directors of the Atlantic telegraph company, is full of interesting information as to the methods employed and the principles involved in these experiments. To the end of the cable a voltaic battery was connected by one of its poles, a galvanometer was placed in the circuit, and the other pole was connected with the earth. The current being then transmitted, the resistance it meets is indicated by the deflection of the galvanometer. The comparative resistance of the cable and that of a given fine copper wire being known, which for one of No. 40 gauge may be as 175 to 1, and the degrees of deflection caused by the cable being accurately read, with batteries of different degrees of strength, the processes are repeated with coils of fine wire, the length of which is added to or diminished until the readings of the galvanometer exactly coincide in every case with those noted when it was connected with the cable. The length of the fine wire will then give that of the cable to the extreme end of the circuit, or to the point where the battery current leaves it to return through the earth. By this method chiefly the electricians came to the conclusion that the fault in the cable was about 279 m., or not more than 800 m., from Valentia; and they also inferred that the wire was not separated, inasmuch as obscure signals were received through it from the other station. This, and the establishment of a current through the wire and back by the earth, also proved that the copper wire could not at the faulty place have come in contact with the iron covering of the cable. The impossibility of raising the cable from deep water without breaking it rendered any attempt to remedy the defect hopeless. Portions of the cable in Trinity

bay on the Atlantic side were recovered in 1860, and in the short time that it had been submerged the iron covering was found to be much eaten by rust, so as sometimes to fall off as the cable was hauled in. In those parts that were wrapped with tarred yarn the iron wires were preserved bright and free from rust. The gutta percha and copper wires seemed to be in as good condition as when the cable was laid. The cost of the Atlantic cable was as follows: for 2,500 m. at \$485 per mile, \$1,212,500; for 10 m. at \$1,250 per mile, \$12,500; and for 25 m. shore ends at the same price, \$31,250; making altogether \$1,256,250. The expenditures of the company up to Dec. 1, 1858, had amounted to \$1,884,500.—After the failure of this great enterprise the attention of some telegraphers was directed to the practicability of extending a cable across the Atlantic from Labrador to Scotland, by way of Greenland, Iceland, and the Farøe islands. The route is about 1,800 m. long, and would present no continuous length of submarine cable for a greater distance than that between Labrador and Greenland, which is about 600 m. Mr. T. P. Shaffner, of the United States, had obtained in 1854 from the king of Denmark a concession of exclusive rights in Greenland, Iceland, and the Farøe islands for this purpose. Failing to interest the government of the United States, Mr. Shaffner chartered a vessel and sailed from Boston, Aug. 29, 1859, to make the preliminary surveys at his own expense. After his arrival in Glasgow, Scotland, the project was brought before the British government, and in June, 1860, a steamer of the royal navy was despatched to take the deep sea soundings, and a private steam yacht was also sent to examine the landing places for the cables and the proposed overland routes. Mr. Shaffner with this expedition again visited the islands and the interior of Greenland, and it is said that a report favorable to the route was carried back to England. No further steps however have yet been taken for establishing this line, and the prospects of its being constructed are not encouraging. The failure of a number of submarine lines, some of which are named below, causes great distrust as to the practicability of keeping up a telegraphic communication across the Atlantic with the knowledge and resources at present available; and the whole subject was generally regarded as abandoned, when, in Feb. 1862, Mr. Cyrus W. Field again visited London with the view of carrying out the original enterprise. He there received from Messrs. Glass, Elliot, and co., manufacturers of most of the submarine cables that have been made, favorable propositions for furnishing and laying a good and durable cable, in the practicability of which they showed their confidence by offering to share the risk. The cable which they laid for the French government between France and Algeria, 520 m. in length, they state, is in perfect and successful working order, under water as deep as any between Newfoundland

and Ireland; and they refer to the following list of cables manufactured and laid down by them, all of which, except three short lines, broken by ships' anchors, are in successful operation:

* Strand.

† Steel covered with hemp.

The line from Malta to Alexandria is laid in sections by direction of the British government; the manufacturers would have preferred to make it a single continuous line. The gutta percha company of London also express full confidence in the successful working, and their readiness to guarantee this, of one of their manufacture. England is connected with the continent by 7 submarine cables. The line from Dover to Ostend, laid in 1852, is 75 m. long, and contains 6 wires. The lines laid in the Black sea in 1855, for communication between the Crimea and Constantinople, were in two sections, one from Constantinople to Varna, 200 m. long, and one from Varna to Balaklava, 150 m. These contained but one wire each. Their cost when laid was £22,000, and they worked with complete success. In 1857 a line was laid, at a total cost of £125,000, from Malta to Corfu in the Mediterranean, on which 400 m. of cable similar to that adopted for the Atlantic route was paid out. This is reported to have failed. The Dutch laid down a cable in 1861 between Batavia and Singapore, a distance of 660 m.; and after conveying a few messages it was several times broken by anchors or coral reefs, and was finally abandoned. The English government a few years since attempted the establishment of a line through the Red sea to connect the telegraphs in India with those of the Mediterranean. This proved entirely unsuccessful, never conveying even a single message throughout, and the project was abandoned, although the government had given a guarantee of 4½ per cent. on £1,000,000 for half a century. A project to connect Falmouth in England with Gibraltar was abandoned after

the cable had been made for this purpose at a cost of £400,000. All these failures are explained chiefly through the neglect of the parties employed in laying the cables, and in no case through insuperable natural obstacles. The Atlantic cable was no doubt originally defective, and was injured beside, first in the way in which it was exposed to the sun, and afterward in the handling, and finally in the laying. Its weight was about 19 cwt. per mile. Some of the earlier cables were much heavier—even 7 tons per mile. For cables to lie in deep water, where no disturbance from anchors, currents, or drifting materials is likely to reach them, great weight beyond that required to sink them is considered of no especial advantage, and the heavy iron coating is found to be altogether useless; but near the shore cables of greater strength and weight are required to withstand the disturbing causes to which they are exposed.—The principles of the electric telegraph are treated in many of the works on electricity, and the ablest papers upon this subject by the most eminent electricians are found in the volumes of the transactions of the scientific societies of Europe. Of the works specially devoted to this subject may be named "The Electro-Magnetic Telegraph, with Reports to Congress," by A. Vail (Philadelphia, 1845); "The Electric Telegraph, its History and Progress," by Edward Highton, C. E., a number of Weale's series (London, 1852); "Historical Sketch of the Electric Telegraph," by A. Jones (New York, 1852); "The Electro-Magnetic Telegraph," by L. Turnbull (Philadelphia, 1853); "The Telegraph Manual," by Tal. P. Shaffner (New York, 1859); and "History, Theory, and Practice of the Electric Telegraph," by George B. Prescott (Boston, 1859).

TELEKY, or TELEKI, LÁSZLÓ, count, a Hungarian patriot, born in Pesth, Feb. 11, 1811, died there in the night of May 7-8, 1861. Belonging to a family distinguished by its possessions and connections in Hungary and Transylvania, as well as by political and literary merits, he early prepared himself for a political career, studying at Pesth and Patak, gained a reputation for rare attainments, contributed to political and miscellaneous periodicals, and in 1837 was elected a corresponding member of the Hungarian academy, of which his half brother Count Joseph Teleky (born 1790, died 1855), the author of the great history of "The Age of the Hunyadya," was the president. In 1842 he published his *Hegyenek* ("Favorite"), a drama, which has since successfully maintained itself on the stage. Having been for some years a member of the diet of Transylvania, he in 1843 took his seat in the upper house of that of Presburg, where he soon became prominent for his eloquence, boldness, decided opposition to the rule of Metternich, and a consistent advocacy of liberal reforms. He subsequently became president of the "Opposition Club" at Pesth; and on the advent of his party to power in 1848 he was elected to the reorganized house

of representatives, in which he sided with the radicals. In Sept. 1848, he was sent as envoy of the Hungarian government to Paris, where he published *Le bon droit de la Hongrie* (1849), and zealously but vainly strove to gain the recognition by the French government of the independence of Hungary, on its proclamation at Debreczin. After the close of the Hungarian war, residing alternately in Paris, Brussels, and Geneva, he continued active in rousing the sympathies of the western nations for the cause of his country by contributions to the press, and in securing by personal representations the moral support of men of high standing. He gained easy access to the French court, during the war of 1859 was a member of the Hungarian national committee in Italy, and toward the close of the following year secretly repaired to Dresden. Here he was arrested by the Saxon police, and surrendered to the Austrian government, who 10 years before had sentenced him to death. The changed condition of affairs in that empire, however, made the execution of the sentence a political impossibility, and the emperor Francis Joseph, in a personal interview with the prisoner (Dec. 31, 1860), restored him to liberty on the promise of severing his connection with the Hungarian refugees and of abstaining for a time from political agitation. The returned exile was received by his countrymen with the liveliest demonstrations, and was soon elected by his former constituents to the newly convoked house of representatives. The diet was opened April 6, 1861, and the leader of the more moderate supporters of the laws of 1848, Francis Deák, prepared an address to the monarch, on which the debates were to open on May 8. Teleky, the leader of the radicals, who opposed any measure looking like a recognition of Francis Joseph as king of Hungary, and any advances on the part of the house toward a compromise, prepared an elaborate and statesmanlike discourse on the situation, in opposition to the address. This discourse was found on his desk, on the morning of the 8th, and near it on the floor the dead body of the writer, pierced by a pistol ball. Doubts on the expediency of his almost revolutionary policy, scruples concerning his word of honor pledged to the emperor, and bodily suffering are believed to have induced him to commit suicide. When the president of the house announced the catastrophe, several of its members burst into tears and the session was suspended. The debate on the address was commenced later, and after a protracted contest Deák's proposition was carried.

TELEMACHUS, a Greek prince of the heroic age, the son of Ulysses and Penelope. When Ulysses went to Troy, Telemachus was an infant, and in his father's absence he grew nearly to manhood. About the time that the gods had decreed the father's return home the son made an unsuccessful endeavor to eject the troublesome suitors for his mother's hand, and

then set out to seek information of his long absent parent. Accompanied by Minerva, who had assumed the appearance of Mentor, a faithful friend of his father, he visited Pylos and Sparta, and was hospitably received by Nestor and Menelaus. From Sparta Telemachus returned home, and on his arrival found his father with the swineherd Eumæus, disguised as a beggar. Their mutual recognition followed immediately, the suitors were slain or driven out, and Telemachus accompanied his father to the aged Læertes. He is called by different authors the father of Latinus, and the founder of the town of Olusium in Etruria.

TELEOSAURUS, a genus of fossil crocodilians of the secondary epoch established by Geoffroy, differing from the living crocodiles in having biconcave vertebrae. The general form of the cranium was that of the gavials; the nostrils opened anteriorly at the end of the muzzle and posteriorly on a level with the jugal arch; the lower jaw was spoon-shaped at the end, with teeth on the sides like canines, the other teeth being small, equal, conical, and adapted for seizing a fish prey; the body was protected by larger and more solid plates, the anterior limbs were smaller, and the posterior more fin-like than in the present crocodilians. The strata which enclose their remains indicate a marine habitat, and their habits were probably those of the gavials. The genus has been divided by modern palæontologists into several subgenera, as given by Pictet. In the lias is found *mystriosaurus* (Kaup), having a very long muzzle, flattened head, and eyes directed upward. The *T. (M.) Chapmanni* (König), from the upper lias of Yorkshire, England, is described in the "Philosophical Transactions" of 1758; the vertebrae were 64, 16 being dorsal, and the teeth about 70 in each jaw; some of the dermal plates were $8\frac{1}{4}$ inches in their transverse diameter; it attained a length of about 18 feet. *Macropondylus* (H. de Meyer) had longer vertebrae and the S-shaped femur not longer than the leg; *pelagosaurus* (Bronn) had the eyes more widely separated, a shorter symphysis of the lower jaw, and the anterior limbs relatively small. The name has been generally restricted to the species found in the oolite, especially the *T. Cadomensis* (Ét. Geoffr.), or crocodile of Caen, from the limestone of Normandy. This is characterized by large orbits near together, a flattened muzzle 5 times as long as wide, very long transverse processes of the dorsal vertebrae, and thick rectangular scales forming 10 regular series, each containing 15 or 16; it must have attained a length of 20 feet. Other genera are *glaphyrorhynchus*, *aeolodon*, and *gnathosaurus* of H. de Meyer. The *T. longirostris* (Ét. Geoffr.) was found in the kimmeridge strata of Havre and Honfleur, and described by Cuvier in his *Ossemens fossiles*.

TELESCOPE (Gr. *τῆλε*, far, and *σκοπεω*, to view), an optical instrument designed to aid the eye in viewing distant objects, causing them to appear magnified by enlarging the

angle under which they are seen, and at the same time increasing their brightness by collecting into the eye a greater number of rays than would naturally enter it. To this instrument we are indebted for almost every item of our knowledge respecting the physical appearance of the heavenly bodies, while to the navigator, the explorer, and the engineer, it is a powerful and often indispensable auxiliary, either as an instrument of research or when adapted to instruments of observation.—The general construction of the telescope is based upon the well known property possessed by a convex lens or concave mirror, of converging to a focus the rays of light falling upon it from any object, and of forming at that focus an image of the object itself. This image may be rendered visible, as in the camera obscura, by interposing at the focus a white screen, a plate of ground glass, or, still more strikingly, a cloud of light smoke within which the image will appear suspended. But if the rays be allowed to proceed without interruption, and the eye be placed in the axis of the lens or mirror and at the proper distance from the focus, the image will be seen more distinctly than before; and if the focus be nearer to the eye than to the lens, the apparent dimensions of the image will be greater than the apparent dimensions of the object itself. This is the simplest, though not the common form of the telescope. Usually a second lens, of shorter focus than the first, is introduced near the image, the effect of which is to increase still further the apparent magnitude of the object; and thus is constituted the ordinary telescope, which, in its elementary construction, consists of an "object glass" or "object mirror," of as large dimensions as practicable, and an "eye lens," which enables the eye to receive the image under the greatest practicable angle. The object glass is always necessarily convex, and the mirror concave, but the eye glass may be either; if convex, it is placed at the proper distance beyond the focus, and, the rays having crossed, the image then appears inverted; if concave, as in the common opera glass, it is placed within the focus, and objects appear in their natural position. The magnifying power of the instrument is measured by dividing the focal distance of the object glass by that of the eye piece; the illuminating power depends mainly on the size of the object glass.—English writers are fond of alleging that the telescope was certainly known to Roger Bacon and used by Digges before the 17th century, but the first really definite accounts of the invention date from the latter part of the year 1608. Magnifying lenses had long been known, and even the compound microscope had been invented by the Janssens nearly 20 years before this date—a discovery which has somewhat embarrassed the study of the question before us from confusion of the by no means explicit terms with which both instruments are described. But it is now generally conceded that the honor of having made the first telescope belongs to one of two

individuals, Hans Lippersheim, a spectacle maker in Middelburg, and Jacob Adriaens, called also Metius, a native of Alkmaar. The former of these, on Oct. 22, 1608, presented to his government three instruments with which "one could see things at a distance," applying at the same time for a "protection" or other equivalent for a patent. Metius made a similar present and a similar application later in the same month, but said that he had manufactured such instruments two years before. It has been frequently stated that Zacharias Jansen also invented the telescope more than a year later; but the evidence adduced only proves, according to Olbers, that he made telescopes which may have been imitated from those of Lippersheim; and this is the more likely as both were spectacle makers in the same city, and it is hardly possible that the public transaction with the latter could have escaped the knowledge of Jansen. The attempt was made by the states-general, it is said, to retain to themselves the knowledge of this invention, whose importance in war was at once perceived by Prince Maurice; but it is also said and believed that the French ambassador soon succeeded in obtaining from them an order for two telescopes for his own government. It is certain that the report of the invention soon spread abroad, and the new and wonderful instruments found their way to London, Paris, and even Venice. But by no person in any city was the idea more eagerly welcomed, or its great importance more quickly recognized, than by Galileo, then visiting at the last named place. He was evidently willing, at a later day, to be thought the second inventor, guided only by an uncertain rumor; but it is reported by some that he actually saw one of the Dutch telescopes, and Huyghens, referring to the matter, declared that the man who could invent the telescope unguided by chance would be more than mortal. Whether seeing the instrument or not, however, his sagacious intellect fully appreciated the great scientific value of the invention; and returning to Padua with some lenses, he immediately began to improve upon what he had seen, if not to experiment independently, under guidance of the mere report, and he soon found a better and more certain result than had been chanced upon by the original inventor. He made a leaden tube, and fitted at one extremity a plano-convex lens for object glass, and at the other a suitable plano-concave for eye piece. This, his first telescope, magnified only three times; he then made another of more than double this power, and soon after, with a magnifying power of 30, the "Tuscan artist" betook himself to the study of the heavens, where his first discoveries excited more wonder than that of the "optic glass" itself. The popular curiosity excited by both was so great, as he himself tells us, that he was compelled night after night, though wearied, to stand by his glass to show its wonderful performances to the curious. But we can scarcely

form a conception of the importance to science of the new invention. The phases of Venus, questioned hitherto, were revealed to sight; the satellites of Jupiter and the oblong shape of Saturn were distinctly seen; the lunar mountains were measured; spots were found upon the sun's disk; the milky way was resolved into stars; and on every side paths were opened for entering upon new and more correct views of the constitution of the universe. In 1609, the same year in which Galileo's telescopes were made, others found their way into England, and were soon sought after with an avidity that was stimulated by the report of Harriot's discoveries. This young astronomer, with zeal and enthusiasm no whit inferior to Galileo's, made drawings of the moon, discovered the satellites of Jupiter, and observed the spots upon the sun. The new "cylinders," as they were called, were soon in general use, and amateurs were greatly delighted with the new aspects of the heavenly bodies, especially of the moon, where they found luminous points "like starres" appearing separated from the main illuminated portion of the new moon, and where, as one expresses himself, "the whole brimme along lookes like unto the description of coasts in the Dutch bookes of voyages." Telescopes were also exposed for sale in Paris in the early part of the same year.—It is generally supposed, in the absence of evidence to the contrary, that these first telescopes were all, like Galileo's, made with a concave eye lens, a construction in which, as has been said already, objects appear in their natural position, but with a very limited field of view. Kepler, in 1611, suggested the use of a convex eye lens; but the first actual application of one was made by the capuchin Schyrle de Rheita, who describes it in his work *Oculus Enoch et Elias* (1645). This eye lens gives a much larger field of view, but shows objects inverted. On the other hand, the Galilean telescope possessed the advantage of greater distinctness and brightness than was found in the "astronomical" form. It was imagined by some that a sort of interference of rays took place at the crossing point, and at first sight, and while the true cause of the indistinctness was unknown, the opinion appeared plausible. Even as late as 1776, the elder Herschel thought it worth while to disprove this idea by an actual experiment, devised with his characteristic ingenuity. The true cause of the advantage of the Galilean form is now known to lie in the partial compensation by the negative eye piece of the aberrations caused by the object glass, the result being in this case the difference, while in the astronomical telescope it is the sum, of the aberrations of the two lenses. Rheita invented also the binocular or double telescope, a construction which frequently recurs afterward, but always as a thing of curiosity rather than of practical utility until in modern days, as the double opera glass or lorgnette, it has become serviceable in reconnoissances, terrestrial and celestial.—The very

first attempts to gain magnifying power and light, by enlarging the object glasses of telescopes, revealed a most unexpected and formidable obstacle. It was found that all objects appeared strongly tinged with prismatic colors. This obstacle remained unexplained until the time of Newton, and unconquered more than half a century longer; and the final victory over it will ever remain as one of the great achievements of the human intellect. But if at the time insurmountable, it did not prove unavoidable, for it was ascertained that by making the focal distance of the object glass very great in proportion to the diameter, the colored fringes could be reduced so as to become practically imperceptible. Enormously long telescopes were therefore constructed, and it was with them that the brilliant discoveries of that day were made. Huyghens used telescopes of his own manufacture, and one of his object glasses, 123 feet in focal length, is still to be seen in the library of the royal society of London. English makers also produced telescopes of nearly equal dimensions, and Auzout in Paris spoke of surpassing all others, but it does not appear whether he succeeded or not. The elder Campani, at Rome, made lenses of from 70 to 136 feet focus, and with these Cassini discovered 4 of the satellites of Saturn, an addition to astronomical knowledge which was thought worthy of commemoration by a medal. Beside the lenses of Campani, some of which are still preserved in Paris, Cassini used also others made by Borelli of 40 and 70 feet, and by Hartzoecker of not less than 250 feet focus. These object glasses were used without any tube, the lens being placed upon a mast, or, as Cassini recommended, at the angle of a tower, and controlled, not without considerable difficulty, by cords leading to the observer at the eye lens.—The source of the inconveniences attending the use of shorter lenses was generally supposed to lie wholly where it did really lie in part, in the imperfect collection of the rays of light, which were at that time believed to be homogeneous, into a simple focus. It was distinctly understood that the rays which passed through a lens near its centre would not be refracted to precisely the same point with those which pass through it near its circumference; that is, there would be what is technically called spherical aberration. This is a true cause, but by no means the whole cause of the indistinctness of images in the telescope. Accordingly, with that belief, it was thought the evil might be remedied by grinding lenses with other surfaces than spherical, and machines were devised by Descartes, by Hevelius of Dantzic, by Du Son of London (who ground deep parabolic concave lenses, with which he asserted that telescopes might be used "with full aperture," and yet show no colors), by Sir Christopher Wren, and others. The main reliance of the astronomer however until near the close of the century was in the aerial telescope, with which, unwieldy though it might be, many

brilliant discoveries were made.—An improvement, of more importance than that of the figuring of lenses, consisted in the modification of the eye piece. By the introduction of more than one convex lens, Rheita had reinverted the image; but this was all the gain that either he or Kepler, who also proposed the same thing, seems to have expected. In fact, there resulted an increase of aberrations which begat distaste of the plan, and it was not until about 1659, when Huyghens invented the combination which still bears his name, that much advantage was gained by multiplying lenses. This eye piece is composed of two convex lenses, whose focal lengths are as 3 to 1, and which are separated from each other by an interval equal to half the sum of these focal lengths; the place of the telescopic image being between the lenses. This arrangement was found to have a remarkable advantage in point of distinctness over the single eye glass, by reason of the apportionment of spherical aberrations between the lenses, and the consequent less amount of injurious effect in the result, while no addition whatever was made to the color of the images formed by the object glass. To this day the "Huyghenian eye piece" remains one of the best combinations for ordinary viewing purposes. Another eye piece, less successful, however, was constructed by Campani with 3 lenses so arranged as to show objects "without any iris or rainbow colors."—In the form to which the refracting telescope had now been brought, it remained full three quarters of a century without further material improvement. But during this interval, by the application of the telescope to instruments of observation, astronomy was continually gaining in the accuracy and extent of knowledge respecting the positions and movements of the heavenly bodies. Morin, professor of mathematics in the college of France, first in 1634 attached a telescope to the moving index of a graduated arc, in order, as he says, "to measure the fixed stars quickly and accurately." He was also the first to gain sight of stars in the daytime. Having, one morning in the early twilight, directed a 1½ foot telescope attached to the alidade of a planisphere upon Arcturus, he followed the star until after the sun had risen; and finding that it still continued visible, his joy was so demonstrative that his instrument was displaced and the star lost. He afterward succeeded in following Venus and other planets, as well as several fixed stars, into the daylight. But it was only after the introduction of fixed threads into the field of the telescope, that it became a really useful auxiliary to instruments of measurement. At the present day it seems at first strange that astronomers should have preferred the simple "sights" or "pinnules," with which they had always been accustomed to observe, to the far more accurate perception furnished us by the telescope; and yet they, without any means of designating the centre of the field of view, and

with only the feeble optical power at their command, were right in their preference. Even as late as 1678, Hevelius, who had spent a long life in the construction and use of large instruments, as well as telescopes, argued earnestly in favor of the pinnules for observing—not, as stated by Whewell, because it would make all the old observations of no value, but rather from a want of confidence in the new method, which he said had not yet proved itself superior, especially in the case of comets. A controversy upon this question arose between him and Hooke, in consequence of which Halley was requested to visit Dantzic and make actual comparison of the two methods. He did so, when it appeared that Hevelius had acquired such skill in the use of his favorite method, that the difference of their observations seldom exceeded a few seconds, and in no case amounted to so much as a minute! As early as 1641, Gascoigne, an accomplished young English astronomer, had applied fixed threads to the telescope. In a letter to Crabtree he says that he has fitted his sextant "by the help of the cane (tube), two glasses in it, and a thread, so as to be a pleasant instrument." The object he had proposed to himself was the improvement of the lunar theory, and he "doubted not in time to be able to make observations to seconds." He had also at this time invented the wire or filar micrometer, in the details of which it is pleasant to find not merely mechanical ingenuity, but also a true appreciation of the astronomical requirements of such an apparatus; and there is no doubt that had the inventor lived to make a more extended application of his contrivance, the results would have been of high value. Gascoigne perished untimely at the battle of Marston Moor, and his invention, of which no account had been published, and which does not seem to have been sufficiently appreciated at the time, remained forgotten until nearly 80 years after, when an opportunity for reclamation occurred upon the reinvention of the micrometer by Anzout. It was about the same period that Roemer gave to the telescope one of its most important applications, by attaching to it an axis at right angles to its length, and placing it so as to revolve in the plane of the meridian; and shortly afterward Picard in Paris, and Flamsteed at Greenwich, following up this capital idea, commenced a new era in observation. For a more detailed account of this application, see TRANSIT CIRCLE.—Mersenne, in his correspondence with Descartes, had before the year 1639 suggested the practicability of using a concave mirror instead of the principal lens in the telescope; but the idea appears to have been unfavorably received by the latter. In 1663 James Gregory, of Edinburgh, published in his work entitled *Optica Promota*, the plan of a reflecting telescope, consisting of a concave mirror, perforated in the centre, by which the rays were to be converged to a focus before it, and after crossing would be received upon a

second small concave mirror, be reflected back by the latter, and, crossing again near the opening in the first reflector, would be there received by a lens and thus transmitted to the eye. The rays having crossed twice, objects would appear in their natural position. An attempt was actually made to construct one of these telescopes; but owing to want of a proper appreciation of the extreme nicety required in the figures of the mirrors, and in the relative adjustment, no satisfactory result was obtained. In 1671 Newton took up the study. By those beautiful and simple experiments, the account of which in his own words so highly claims our admiration, he soon found the true cause of the prismatic colors which had proved such a stumbling block to the progress of the instrument, and arrived at the conclusion "that the perfection of telescopes was hitherto limited, not so much for want of glasses truly figured according to the prescriptions of optic authors, . . . as because that light itself is a heterogeneous mixture of differently refrangible rays. So that, were a glass so exactly figured as to collect any one sort of rays into one point, it could not collect those also into the same point which, having the same incidence upon the same medium, are apt to suffer a different refraction." Abandoning therefore as hopeless all further attempts at improvement in this direction, he was led "to take reflectors into consideration," since here there would be no separation of colors; but inasmuch as any irregularity of figure in a concave mirror would produce greater distortion in the image than would be the case with a lens, "a much greater curiosity would be requisite than in figuring glasses for refraction." The Gregorian construction, mentioned above, appeared to him to have such disadvantages, that he "saw it necessary to alter the design, and place the eye glass at the side of the tube." Having then found an alloy of copper and tin which appeared to possess the requisite qualities for mirrors, and having also devised a "tender way of polishing proper for metal," he attempted the construction of a reflecting telescope upon the plan which has ever since borne the name of Newtonian, and soon succeeded in making an instrument with which he could discern the "concomitants" of Jupiter and the phases of Venus. Another one made soon after, having a speculum of $1\frac{1}{2}$ inches diameter and $6\frac{1}{2}$ inches focus, was presented by him to the royal society of London, by whom it is still preserved. In these telescopes the mirror is placed at the lower end of the tube, whence it reflects the rays forward toward a focus; but before reaching this point, their course is diverted by a small plane mirror inclined to the axis at an angle of 45° , so that the image is formed at the side of the tube near its mouth, and is there viewed by the eye lens, so that the observer looks in a direction at right angles to that of the object. In the same year that Newton's telescopes were made, Cassegrain, a

Frenchman, proposed still another construction, which bore a similar relation to the Gregorian that the Galilean refractor does to Kepler's. The large mirror was perforated, but the rays proceeding from it were, before reaching their focus, received upon a small convex mirror which sent them back with less convergence to form the image near the eye piece. It was asserted that this form, which, like Gregory's, was not immediately brought into use, would possess several advantages over the Newtonian; but the English philosopher showed that these advantages were rather objections, and that the difficulty of properly working the mirrors would always be a serious obstacle to their general acceptance. In fact, we hear little more of them until some 70 or 80 years later, when Short, a celebrated artist of Edinburgh, revived their manufacture, and, by his peculiar skill in figuring and mutually adapting the mirrors, "marrying them," as he termed it, brought them into favor for a time. But practical difficulties, especially in the manipulations of the large speculum, interposed for many years to prevent even the Newtonian construction from coming into general use. It was known indeed that in order to reflect all the rays accurately to the same focus, the figure of the mirror should be not spherical but parabolic; but no method was known whereby this figure could be attained with certainty. At length, in 1718, Hadley succeeded in making a mirror 6 inches in diameter and with a focal length of 62 inches, which bore a magnifying power of 280. This instrument may be considered to have established the reputation of reflectors; for on being compared by Bradley and Pound with the 123-foot aerial telescope of Huyghens, it proved fully a match for the refractor, except that the latter showed objects somewhat brighter. But those practised observers were able to see nothing with the Huyghenian telescope which they could not see also with the reflector, and sometimes the latter had the advantage. After this period reflectors came rapidly into general use, and have ever since, as indeed they were from the first, been the favorite kind of telescope in England. Their construction was greatly facilitated to practical men by the appearance in 1777 of an elaborate memoir by Mudge, giving a detailed account of his process of making and finishing specula; a memoir for which the author received the royal society's gold medal. Another important memoir upon the same subject by the Rev. John Edwards, was published in the appendix to the "British Nautical Almanac" for 1787.—About the year 1766 a small telescope, only two feet in length, fell into the hands of a German organist residing in England. His curiosity and zeal were both aroused; he sent to London for a larger instrument, and, finding its cost too great for his then limited means, undertook to make one for himself. The organist was the elder Herschel. With rarely equalled perseverance and mechan-

ical ingenuity, he devoted all the time at his command to the manufacture of reflectors. Improving continually upon his successive results, and with increasing means at his disposal, he made many Newtonian reflectors, some even as large as 20 feet, as well as a number of the Gregorian form of 10 feet focus; in the course of all which work he acquired naturally most profitable experience. Astronomical observation also went hand in hand with his mechanical progress, and the pages of the "Philosophical Transactions" bear abundant testimony, not only to his skill and success in observing, but also to the great philosophical powers of his mind. The discovery by him of the planet Uranus, in 1781, brought him to the favorable notice of George III., by whose liberal patronage he was enabled in 1785 to undertake the construction of the celebrated 40-foot reflector, which under these auspices progressed rapidly to completion. The instrument was pronounced finished in Aug. 1789, when the labors of the persevering and zealous astronomer received their first reward in the discovery of the 6th satellite of Saturn. The tube of this great telescope was of sheet iron, nearly 40 feet in length, and more than 4 feet in diameter. The speculum, weighing 2,118 pounds, had 48 inches of effective aperture, and was $3\frac{1}{2}$ inches thick. By slightly inclining it, the rays forming the image were thrown to one side of the tube, just beyond its mouth, and there received by the eye piece directly, thus saving the percentage of light ordinarily lost by the second reflection. The motion of this massive instrument was effected by means of a symmetrical arrangement of masts and ladders, which formed a framework or scaffolding within which the telescope could be not only supported, but directed with ease and certainty to any part of the heavens. After the lapse of 50 years, during the latter portion of which the telescope had lain unused, it was dismounted by Sir John Herschel at the end of 1839, and on New Year's eve his family assembled within the tube and sang its requiem. It now rests horizontally upon three stone pillars, a monument to the memory of its constructor.—It would seem that the improvement of the refracting telescope after the middle of the 17th century was long retarded in consequence of the opinion, quoted above, of one whose views were always to be received with deference. Newton evidently conceived that the prismatic rays of light, once separated, could not be recomposed into white light except by the same refraction that had separated them, and that therefore the removal of these colors from a telescopic image was impossible. The opinion was seemingly self-evident, and yet was incorrect. The weight of Newton's authority, however, was sufficient for a time to repress further investigations in this direction; and it was not until 1729 that an Englishman named Hall, guided, it is said, by a study of the mechanism of the eye, was led to a plan of combining lenses so

as to produce an image free from colors. Telescopes were made according to his directions, and were said to perform well; but the secret of their construction died with him, and no public account of the facts was given until called forth by later occurrences. In 1747 Euler, referring to the construction of the human eye, declared that a combination of lenses of different media was possible which should give a colorless image, and investigated analytically the curvatures for a lens compounded of glass and water. His result was questioned, singularly enough, by the man from whom opposition might have been least expected, John Dollond, who, relying too implicitly upon Newton's dictum, was contending against his own future fame. His questioning, however, partook more of the nature of the same dictum itself than of argument, and he was soon led to consider the subject more attentively by the remark of a Swedish mathematician, that there were certainly some cases to which Newton's rules did not apply. Thus shaken in his confidence, Dollond undertook experiments, at first with prisms of glass and water, and soon found that when the prisms were so combined that the rays passed through without refraction, they were tinged with the colors; next, arranging the prisms so that the rays appeared without colors, he found them displaced by refraction. Here, then, was in his hands the grand principle which was to make a revolution in the construction of the telescope. He pursued the study, and arrived at the same results by using prisms of crown and flint glass. From prisms to lenses the transition was easy, and his triumph was finally completed, when, having combined a convex lens of crown glass with a suitable concave of flint, he was able to correct the colors and leave sufficient refraction outstanding to produce a telescopic image. And now, singularly again, it was Euler's turn to doubt. He still believed all kinds of glass alike in their optical properties, and that it was only some happy combination of curvatures at which Dollond had arrived. But his doubts soon gave way before experience, and the masterly powers of his analysis were brought to bear successfully upon the problem of the compound object glasses. The subject attracted universal attention, and mathematicians everywhere contributed toward perfecting by theory the requisite conditions of curvature of the lenses. The new telescopes were appropriately called achromatic, or free from color, and henceforth the "dispersive power" of any medium, by virtue of which the differently colored rays are differently refracted—that is, are dispersed from each other—was recognized as independent of the "refractive power," by virtue of which the whole pencil is diverted from its original source. Side by side with the theorists was Dollond with his practical skill. Attempting, in 1758, to make double object glasses of short focal distance to be used with a concave eye lens, he found difficulties in the man-

agement of the spherical aberration, whereupon the idea occurred to him of dividing this aberration by having two lenses of crown glass and including the flint lens between them, an arrangement which accomplished the purpose in view, but did not succeed with convex eye pieces also. Afterward, his son Peter, whose own skill combined with his father's inventive genius to render the name of Dollond inseparably associated with the history of the telescope, resumed these experiments, and as a result presented to the royal society of London a triple object glass of $3\frac{1}{2}$ feet focal length and $3\frac{3}{4}$ inches aperture, with which the telescopic image was pronounced by Short, an excellent judge, to be "distinct, bright, and free from colors." The proper combination of three lenses into a system in which any the least departure from harmonious action will offend the practised eye, if not vitiate the whole action, was of course recognized as a matter requiring the utmost delicacy. A beautiful suggestion was made by Wollaston of a means of testing and correcting the concentric adjustment of lenses. By removing the eye glass of a telescope and viewing any bright object, as a lighted candle, through the object glass, there may be observed at the same time with the refracted image a series of fainter images formed by the second reflections from the different surfaces. It is evident, then, that if the glasses be truly centred, these images will all be in the same straight line; or if there be any error of position of either lens, it will be decidedly manifested, and by proper adjusting screws may be corrected accordingly.—Among the many mathematical solutions of the new problem of the object glasses, the precepts given by Klügel, in his "Dioptrica," commended themselves to the general apprehension, and served as a basis for subsequent fruitful investigations. These precepts were: 1, that the radii of curvature of the first, or crown lens, should be such that the angles of the incident ray with the normal would be equal at both surfaces, which would give for crown glass a ratio of nearly 1 to 3; 2, the radius of the third surface, the first of the flint lens, should be such that the rays of mean refrangibility passing through both the centre and edge of the lens would unite as nearly as possible in the same part of the axis, so that the spherical aberration would be sensibly destroyed; and 3, having determined the outstanding dispersion for the red and violet rays, the fourth surface should be made such as to unite these rays as nearly as possible in the same point with the rest. Early in 1816 Bohnenberger, commenting upon these precepts, showed that, by changing the ratio of the first two surfaces from $\frac{1}{2}$ to $\frac{3}{8}$, the proportion of aperture to focal length could be materially increased without prejudice to the performance of the instrument. Not long after, Gauss remarked that it was possible, theoretically, to construct an object glass which would unite all the rays of any two colors as well as

the mean rays at the centre and at a given distance therefrom into one and the same point. Both lenses should be concavo-convex in form, and with a proportion of aperture to focal length of $\frac{1}{15}$ he obtained an almost perfect union of rays. The unusually deep curvatures of the lenses seem to have occasioned some scruples on the part of opticians, and this construction remained almost forgotten for 40 years, until Steinheil, with characteristic boldness, has recently taken up the study, found and conquered the practical difficulty, and has arrived (in 1860) at complete success in the manufacture of the Gaussian object glasses.—The proper construction of eye pieces was also a matter of some consideration. Beside the Huyghenian form already mentioned, and which is only applicable for viewing objects, Ramsden, in 1783, introduced another, which is still used in micrometer observations. It consists of two plano-convex lenses, of equal focus, with their convex surfaces toward each other, and separated by a distance of two thirds of the common focal length. By this arrangement, to which he was guided by a remark of Newton, the essential condition of a "flat field" is gained, and the aberrations, chromatic and spherical, are so much reduced as to be practically insensible. For terrestrial observations, the elder Dollond sought to reduce aberrations and enlarge the field of view, by increasing the number of lenses, and, after having first improved the 4-glass eye pieces already in use, obtained, by adding yet a 5th lens, a combination which very satisfactorily effected both the desired objects.—Among the distinguished names connected with the history of the telescope, some, like those of Euler and Gauss, brought lustre to it; others, like Dollond's, received lustre from it. The name of Joseph Fraunhofer did both. Devoting the labors of a life (see *FRAUNHOFER*) all too short for science to the improvement of the achromatic telescope, he studied the theory of light and the laws to which it was subject in transmission through various media, and, by aid of his own ingeniously devised apparatus, gained perfect familiarity with all its modes of action. Then, fully appreciating the obstacles to practical application of this knowledge, lying in the difficulty of procuring disks of homogeneous flint glass, his mechanical ingenuity contended successfully against this difficulty. The process by which his glass was manufactured is kept a secret, but it is generally understood that the disks themselves are obtained by selecting and melting together the most faultless specimens from larger masses of the best glass, whose constituent parts however are not known. Having now the glass, he well knew how to combine curvatures to suit its peculiar properties, and the results are to be found all over Europe. His life's labors were fitly crowned by the completion, in 1824, of the splendid telescope for the observatory at Dorpat, a masterpiece which excited no less wonder than admiration. The object

glass of this instrument—double and not triple, as stated by some writers—has a clear aperture of 9.6 inches, and a focal length of 170.5 inches. Its optical performance is of the highest character, such that Struve did not hesitate to pronounce it unsurpassed in this respect by any in existence. It gave to the stellar images a perfect sharpness of definition, which enabled it not only to resolve the closest known double stars, but also to discover as double or multiple others that had passed unchallenged before the exquisite 20-foot reflectors and the practised eye of the younger Herschel. But the true hand of the artist was shown in this instrument no less in the mechanical than in the optical part; and the best evidence of his success in foreseeing and meeting every requirement of the astronomer is in the fact that his style of “mounting” the telescope remains to this day essentially unimproved, and has served as the model for subsequent artists. Fraunhofer died at the early age of 39, and the two words inscribed upon his tomb tell the truth: *Approximavit sidera*.—The manufacture of optical glass has received much attention in England. In 1824 a committee was appointed by the royal society to take into consideration the theory and to experiment upon the manufacture of such glass. Their chief labors devolved upon three members, Dollond, Faraday, and Herschel. The first results were reported to the society in 1829. The efforts of this committee were directed to the manufacture of very heavy glass, and they succeeded in obtaining disks of 7 inches, which seemed, so far as tried, to answer all the requirements of the telescope. Dr. Ritchie also devoted much attention for several years to the same subject, and with considerable success, but was prevented by premature death from publication of any of his processes. Mr. Simms, who obtained most of the glass, applied afterward to Messrs. Chance and co. of Birmingham, who had manufactured it according to Dr. Ritchie's instructions, for information relative to the matter, but received only unsatisfactory answers. Judging by the appearance of the glass as it came into his hands, Mr. Simms inferred that it had been fused in moulds and there subjected to pressure. The largest disk had 7½ inches diameter, and was ground for use by Simms himself. It was, on trial, found to be “an excellent glass, but not altogether faultless.” In this state of difficulty respecting large disks of flint glass, the idea occurred to some that the desired achromaticity might be obtained by separating the lenses and placing the flint at some distance down the tube in the narrowing cone of rays. In 1828 Alexander Rogers proposed to introduce in combination with the crown lens a smaller compound lens of plate and flint glass, in which the refraction is entirely destroyed, and the outstanding dispersion left available for the desired correction of that of the outer lens. The investigation of the requisite curvatures of this compound lens

was found to present no peculiar difficulty; and moreover the final perfection of the compensating action could be accomplished by proper adjustment of the relative positions of the lenses, so that less rigorous accuracy is requisite in their mechanical formation. Upon studying the details of construction, Rogers found it probable that a telescope of 18 feet focal length, and with a crown lens of 12 inches aperture, could be made achromatic with a flint lens only 4 inches in diameter. Four years later this same construction was introduced into actual use by Plossl at Vienna, and his success was such as to attract considerable notice. The new form received the name of “dialytic” or separated telescope. One of them, in the possession of Schumacher, having an aperture of 2½ inches and focal length of 3 feet, was described by him as of extraordinary excellence of defining power. Both Schumacher and Struve, the latter doubtless the best living judge of telescopic performance, said that they had never seen a telescope of equal dimensions that could compare with this. Afterward Struve, canvassing Europe for masterpieces worthy to adorn the new observatory at Pulkowa, visited Vienna, and while there compared a dialytic telescope of 8½ inches aperture, bearing a magnifying power of 135, with a Fraunhofer telescope of half an inch greater aperture and a power of 210, and was scarcely able to perceive any superiority in the Munich glass. The possibility also of making telescopes achromatic by combinations of other media with glass naturally received due attention. Telescopes with lenses of rock crystal and glass were advertised to be made in Paris by Cauchoix in 1831, and some few came into favorable notice; but, it is hardly necessary to say, the difficulty of obtaining the materials in proper shape and size will be a permanent obstacle to their general manufacture. A better idea was suggested, and carried into practice also, by Dr. Blair, who aimed at something more than the ordinary correction of colors. It had long been observed that, even in the best telescopes, there were residual colors having their origin in the want of a perfect correlation of the colored spaces in the spectra formed by the crown and flint lens; so that if any two colors be made to unite at the same focus, as in the ordinary object glasses, there would not be at the same time a complete union of the rest. This want of correlation is called the “irradiation” of the colored spaces, and its effect is known as the “secondary spectrum.” Blair, by a beautiful refinement of the original theory, first made each lens of his object glass independently achromatic, and in such a way that their secondary spectra corrected each other. This he accomplished by using fluid media, two lenses of which were enclosed in combination with three of glass. Moreover, in the course of his experiments, he discovered that muriatic acid combined in proper proportions with metallic antimony gave a spectrum in which

the colors had exactly the same proportions as in crown glass; and therefore by enclosing this fluid between two crown lenses, one a plano-convex and the other a meniscus, he obtained the gratifying result of a telescope absolutely free from colors. The name "aplanatic," or without error, was given to this combination. Another fluid-lens telescope, of the dialytic form, was constructed by Barlow, who made use of the high dispersive power of sulphuret of carbon, a beautifully transparent and colorless fluid. He was able to render achromatic a combination of a crown lens 8 inches in diameter with a fluid lens of half the size. There is however a practical objection to the use of sulphuret of carbon arising from the variability of its density by variations of temperature. By actual experiment, Barlow ascertained that in the first mentioned telescope, the refractive index of the fluid would be changed by one tenth of its whole amount by a change of temperature from 32° to 212° . This susceptibility would require a more habitual determination of the corresponding effect upon the value of a revolution of a micrometer screw when one is used with such an instrument.—Reverting to what may be called the regular construction of achromatics, we find that the successors of Fraunhofer at Munich, and Guinand and Cauchoix at Paris, have succeeded in producing object glasses of dimensions far superior to those of the Dorpat lens. Disks of 10, 12, and even more inches in diameter have become familiar to these master opticians, whose skill in working them keeps even pace with their manufacture; and two Munich telescopes, each with more than 15 inches of clear aperture, one at Pulkowa and the other at the observatory of Harvard college, have for years, in the successful exercise of their wonderful powers, been adding richly to the stores of astronomical knowledge.—A few attempts have been made in the United States to manufacture optical flint glass, but they have hitherto been but partially successful, and that with only small disks. But the American-wrought object glasses have earned for themselves a high place. Many have been made in New York by Henry Fitz, and submitted to the test of comparison with Fraunhofer's lenses, size for size, nor are we aware that the test has failed in a single instance. His largest glass, 18 inches in diameter, was made for the Dudley observatory at Albany. Spencer, already famous for the excellence of his microscopic objectives, has made for Hamilton college a $18\frac{1}{2}$ inch telescope, which is highly commended. But in exquisiteness of workmanship and performance, the object glasses made by Alvan Clark, of Boston, have fairly distanced all competitors, native or foreign. Whoever will glance over the list of close double stars discovered with his 7 and 8 inch lenses (see "American Journal of Science," vols. xxv. and xxix.) will remark several stars that must have passed unnoticed under the review of Struve with his superior op-

tical power. Mr. Clark has recently completed a magnificent object glass of $18\frac{1}{2}$ inches in clear aperture and with a focal distance of 28 feet, the largest in the world, if we except one of 20 inches diameter upon which Porro, in Paris, is said to be now engaged. Mr. Clark's object glass is made from disks of Birmingham glass, which have a uniform density and freedom from veins, and, though only rudely mounted as yet, has already revealed the duplicity of the minute companion of α^3 Capricorni; and in Jan. 1862, it detected a companion to Sirius, perhaps the hitherto invisible one whose workings have been indirectly manifested in the variable movement of the larger star. It is probable that this masterpiece, prevented from reaching its original destination, will now be secured for the observatory of Harvard college.—In England, the attention of the mechanical astronomers, if we may so call them, has been of late years more especially occupied with the construction of large reflecting telescopes, and preëminent in this department is Lord Rosse, who about 1848 completed a telescope which has a clear aperture of 6 feet and a focal length of 58 feet. This enormous instrument has two specula, one about $8\frac{1}{2}$ and the other about 4 tons in weight. At first each rested upon a system of 27 platforms most ingeniously arranged to distribute their support of this enormous weight in such a manner as to produce equal pressure in every position of the instrument. The vital importance of securing this equilibrium of all parts of the speculum is best illustrated by the remark of the maker, that a strong pressure of the hand at the back of a speculum 4 tons in weight and nearly 6 inches thick produces flexure sufficient to distort the image of a star. At a later period 27 triangles, each with a ball at each angle, were substituted for the platforms, so that now the speculum rolls freely on 81 balls. The tube of the telescope is supported upon a massive universal joint of cast iron resting upon a pier of stonework built in the ground, and it is so counterpoised by a chain suspension applied at the centre of gravity, that it can be moved with great facility, a quick motion being given by a windlass below, and a controlling slow motion in either direction by hand of the observer above. Various micrometers have been tried with this instrument, but the common filar micrometer with coarse threads answers best; and such is the quantity of light collected by the immense reflecting surface below, that the threads in the micrometer are always distinctly visible without artificial illumination even in the darkest night. This illustration of the illuminating power of such a telescope reminds us of a similar one related by Herschel, who said that with his 20-foot reflector he could read the figures on the dial of a church clock when the twilight was so far advanced that the tower itself of the church could not be seen by the naked eye. The general processes of casting, grinding, and figuring these large specula have been already de-

scribed in the article *SPECULUM*. Several other large reflectors have been constructed by Lassell, De la Rue, and Nasmyth; and very recently the first of these has succeeded in transporting to Malta a Newtonian telescope 4 feet in diameter. De la Rue has successfully applied his large telescopes to celestial photography, in which he has made many important improvements.—The manufacture of reflecting telescopes with glass specula has of late received a new impulse from the discovery by Liebig of a process of coating glass with an infinitesimal film of pure metallic silver. From the first days of reflectors, as early as Newton, we find a proposition to substitute a silvered lens for the metallic mirror of his telescope, on account of the greater perfection with which glass could be wrought, and the greater durability of the polished surface. In 1740 Caleb Smith showed how, with glass mirrors silvered upon the posterior surface, the rays of different refrangibility, after twice passing through the glass, and thus becoming separated, might be united again by the action of a small concave lens placed not far from the focus of the mirror. The elder Herschel sometimes used glass reflectors for his smaller telescopes. In 1822 Airy proposed a combination of two silvered lenses in the Gregorian or Cassegrainian form, and showed how, by proper mutual adjustment of the two, a perfect achromatism might be obtained. In 1838, and again in 1841, Barfuss of Weimar investigated the theory of telescopes with glass mirrors, and found that, of the various forms of reflectors, the Cassegrainian was best adapted for this construction. He demonstrated that in this form both chromatic and spherical aberration may be sensibly corrected in a telescope of 20 inches focus with full 5 inches aperture, and that such a telescope would bear even a power of 600. But by Liebig's discovery a still better field has been opened. His process consists in precipitating the silver upon the glass surface from an alkaline solution prepared by addition of caustic soda to the ammonio-nitrate. After immersing the glass for about three quarters of an hour, an extremely thin and regular film is obtained which has a slight bronzy hue by reflected light, and will transmit a deep blue light when interposed between the sun and the eye. This film is said to be harder than ordinary silver, and, by friction with soft leather and perhaps a little dry rouge, is susceptible of receiving the most brilliant polish externally, while it answers perfectly in figure to that of the glass beneath. Foucault has also made use of a process of similar nature (see *SPECULUM*), and succeeded in constructing telescopes of considerable dimensions. One was made by him of 13 inches aperture and only 88 inches focus, with which, under a magnifying power of 600, he could separate the components of the small companion of γ Andromedæ. Even now (1862) he is completing for the Paris observatory a silvered mirror of 81 inches diameter, which is not yet definitively mounted,

but with which Chacornac has found and measured the position of Clark's satellite of Sirius. Steinheil, investigating the relative reflecting power of a speculum coated by this new process, as compared with others and with the transmitting power of some object glasses, found that, under an angle of reflection of 45° , the amount of brightness obtained was as follows:

Direct light.....	100
Silvered mirror.....	91
Quicksilver glass.....	76
Metallic mirror, one reflection.....	67
Herschel gives also:	
Newtonian telescope.....	44
Gregorian or Cassegrainian.....	40
Steinheil:	
Object glass by Fraunhofer transmits.....	76
Object glass by Steinheil.....	57

But beside the gain in brilliancy, there is another, less important perhaps, but by no means inconsiderable advantage; for we are now able to substitute for the heavy and intractable speculum metal a disk of glass which is far easier to cast and anneal, and being much firmer can be made of less than half the weight of the present mirrors. We may therefore look with confidence for the yet greater perfection of reflectors, and for corresponding progress in discovery.—A beautiful application of glass mirrors, unsilvered, has been proposed by Sir John Herschel and realized by Porro of Paris, for use in observations of the sun. It is customary in these observations to diminish as much as possible the aperture of the telescope, and to protect the eye by using shades of stained glass. Still, great inconvenience is felt from the intense heating power of the concentrated solar rays, which frequently breaks the shades, and, in long continued observation, always causes trouble and straining to the eye. Herschel proposed to use only the very small portion of light reflected from the first surface of glass, by constructing the large mirror of a Newtonian telescope of a double-concave, well polished lens, whose first surface only is truly figured to serve as reflector for the 2.6 per cent. of rays untransmitted and unabsorbed. The lower end of the telescope tube being left open, all the remainder of the light passes out and is dispersed. But even the small amount of reflected rays is still further reduced by the second reflection, which is made to take place at the first surface of a prism whose refracting angle should not be less than 30° or 40° , so that now the portion of light finally reaching the observer is but $\frac{1}{1375}$ of the direct illumination, in consequence of which immense reduction a very light shade only is needed to protect the eye. Porro, in constructing a telescope upon this principle, improved it by placing the prism for the second reflection at the polarizing angle for glass, whereby, upon introducing a Nicol's prism, the light may be enfeebled as much as desired without using any shade at all.—The proper construction of the support or stand upon which the telescope is to rest, and by which it is to be directed to the heavens, is a matter of very great impor-

tance; for it has more than once happened that good telescopes have been condemned, and they may frequently be rendered useless, by the defective manner of their mounting. The great requisites of a telescope stand are firmness and stability, combined with a facility of motion which will allow the instrument to be pointed with ease and certainty to any part of the heavens. Fraunhofer, whose plan is now generally followed, adopted the equatorial form, as it is called, which consists essentially of a polar axis upon which the whole instrument is moved parallel with the celestial equator, and which carries in a socket another axis at right angles to itself, upon which latter the telescope moves from or toward the pole. By the combined motions command of the whole visible hemisphere is given, and with the advantage that, the instrument being once directed to a star, the observer can follow it in its diurnal path by motion upon the polar axis alone; moreover, by application of a simple train of wheel-work this motion can be effected by machinery, and the observer is thus enabled at his leisure to contemplate or to measure the objects which appear fixed as though in an immovable sky. This elegant appliance was made by Fraunhofer, who so beautifully and accurately balanced every moving part of his instruments, that the slightest force was sufficient to keep the whole in motion. In the immense English reflectors, the lower end of the tube rests upon the ground or some solid support, and even then for the needful motions of the instrument powerful appliances of machinery have been required; but in latter days mechanical engineers have been able so to combine and counterpoise great masses of cast iron machinery, as to effect with wonderful ease every delicate movement desired by the astronomer, and now the idea of mounting even these large telescopes equatorially is growing familiar. The application of clockwork movement to such large reflectors renders it practicable to use them for celestial photography, as well as for some of those extremely delicate astronomical measurements which the science is now demanding for the resolution of sundry long vexed problems.—The application of the telescope to meridian instruments is exemplified in the article **TRANSIT CIRCLE**; but the telescope is also universally used for differential measurements. When applied to this class of observations, various modifications or appliances have been from time to time suggested or practised. The filar micrometer is the most common auxiliary of the telescope, and in skilful hands is capable of astonishing accuracy. Great use has also been made of the power of producing and comparing together double images of the objects to be measured. These double images are produced in various ways. Savary in England in 1743, and Bouguer in France some 4 years later, proposed, independently of each other, to measure the diameter of the sun by using

two object glasses in the same telescope and with the same eye piece. In Savary's plan, the glasses were all fixed so as to give two images of the sun whose outer edges were nearly in contact; and by measuring the variable distance of these edges, he obtained the corresponding variations of the semi-diameter from perigee to apogee. Bouguer's invention was more generally applicable, for he made one of his object glasses movable, and thus could measure any angle from zero to his maximum limit, which was probably somewhat greater than the sun's diameter. In 1758 John Dollond invented the divided-object-glass micrometer, which has in later years, under the technical name of heliometer, achieved such wonders in the hands of Bessel and his followers. In this instrument the object glass itself when finished is divided into two equal segments, each of which forms its image independently of the other. When the semi-lenses are brought to their normal position of coincidence, the two images coincide also; but when separated, the images diverge, and the angle of divergence is measured by the amount of separation of the lenses. Thus the apparent diameter of a planet, for instance, is obtained by separating the images until their outer edges are in exact contact, and this may be more accurately perceived than the coincidence of the edge with a fine thread placed tangent to it as in the filar micrometer. Dollond proposed moreover to gain both accuracy and convenience of use by placing a divided object glass of very long focus before the speculum of a reflecting telescope, which would give a larger scale for the measurement of a given angle than would belong to a simple telescope of the same length. Fraunhofer was at the time of his death engaged in devising a heliometer which, when afterward completed, was placed at Königsberg. Bessel, whose "Theory of the Heliometer" is one of the most elaborate and beautiful monographs of astronomy, was able with this instrument to grapple successfully with that even now most difficult practical problem, the measurement of the parallax of a fixed star. Several attempts have also been made, as by Rochon, Maskelyne, and Boscovich, to produce the double images by refraction through prisms or pairs of prisms, either beyond the object glass, or sliding within the tube, as well as by dividing the small mirror of reflecting telescopes, as Ramsden suggested for the Cassegrainian form, and Brewster for the Newtonian. Divided-eye-lens micrometers have also been made, the best form of which is that given by Airy, who found the four-glass eye piece best adapted for this purpose, and divided the second lens, counting from the object glass. There is, however, in all the arrangements of divided lenses, an essential imperfection arising from the exhibition of color and of some diffraction in the direction at right angles to that of the line of separation, and this practical inconvenience may be seriously felt in some

classes of observations. On this account, it will probably yet be found most advantageous to make use of the double refracting property of certain crystals for the separation of images.

TELFAIR, a S. co. of Georgia, bounded S. and W. by the Ocmulgee and N. E. by the Little Ocmulgee river; area, 925 sq. m.; pop. in 1860, 2,713, of whom 886 were slaves. The surface is level and the soil sandy, with extensive pine forests. The productions in 1850 were 77,085 bushels of Indian corn, 44,250 of sweet potatoes, and 572 bales of cotton. There were 14 churches, and 248 pupils attending public schools. Capital, Jacksonville.

TELFORD, THOMAS, a Scottish civil engineer, born in Westerkirk, Eskdale, Dumfriesshire, Aug. 9, 1757, died in Westminster, Sept. 2, 1834. At the age of 14 he was apprenticed to a stone mason, and in 1780 went to Edinburgh, and while there in all his intervals of leisure studied architecture and drawing. Two years later he removed to London, and was employed by Sir William Chambers on the quadrangle of Somerset house, then building. He was afterward employed for 8 years as architect in the Portsmouth dockyard, then upon the alterations of Shrewsbury castle, and in the construction of numerous bridges, one of which over the Severn had a flat arch of 130 feet span. He superintended the construction of the Ellesmere canal, 103 miles in length, and requiring several extensive aqueducts over the valleys, which he built for the first time of iron; the Caledonian ship canal, whose locks surpassed any previously built in size; and 6 other canals of considerable extent in England and Scotland, the Götha canal in Sweden, an immense tunnel at Harecastle on the Grand Trunk canal, and the works executed under the commissioners of highland roads and bridges, which included the construction of 1,000 miles of new road and 1,300 bridges, and the improvement of several harbors. The St. Katherine docks of London, the improvement of the Aberdeen and Dundee harbors, the construction of iron bridges with flat arches of 170 feet span, and above all the great Menai suspension bridge, were among his subsequent engineering triumphs. He was elected a member of the royal society of Edinburgh in 1803, and of that of London in 1827. He was president of the institution of civil engineers from 1820 till his death, and bequeathed to it £2,000 for a premium fund, together with all his scientific books, prints, and drawings. Beside the account of his labors on public works, which, with additions made by his executors after his death, constituted a biography, and was published under the title of "Life of Thomas Telford, Civil Engineer, written by Himself" (4to., with a folio volume of plates, 1838), Mr. Telford in early life published some poems under the signature of "Eskdale Tom."

TELL, WILLIAM, the legendary hero of the Swiss revolution, born at Bürglen, canton of Uri, in the latter part of the 18th century, died in 1854. The holder of a farm belonging to

the abbey of Fraumünster in Zurich, he married the daughter of Walter Furst of Uri, and joined the patriots, who, meeting on the Rütli under the leadership of his father-in-law, of Werner Stauffacher of Schwytz, and Arnold von Melchthal of Unterwalden, Nov. 7, 1307, swore to overthrow the tyranny of the Austrian bailiffs. Passing one day with his son through the market place at Altorf, where Hermann Gessler, the bailiff of Küssnacht, had caused a pole to be erected with the dual hat of Austria on its top, he, notwithstanding orders to that effect, declined uncovering his head as a token of submission. For this offence he was arrested and brought before Gessler, who threatened him with death. On second thought, the bailiff, who had heard that Tell was the most skilful bowman among his countrymen, told him that he could redeem his life by shooting an apple from his own child's head. Vainly did he beg the tyrant to be relieved from so dreadful a trial; he was compelled to obey. Gathering all his energy and invoking the Almighty, he succeeded; and in the fulness of his joy was embracing his son, when an arrow was discovered which he had concealed in his bosom. "What was it for?" asked the bailiff. "To kill you if I had hurt my boy," was the answer. He was immediately chained by order of the bailiff, who, taking him in his own boat, intended to have him incarcerated in the castle of Küssnacht; but during the sail across the X. bay of the lake of Lucerne, a storm arose which put the craft in imminent danger. Tell was a good boatman; by order of Gessler he was unfettered, grasped the rudder, and soon brought the boat safely near to the land; but now, seizing a favorable opportunity, he sprang upon a projecting headland, which is still known as "Tell's Rock" or "Tell's Leap," while he pushed back the boat into the surf. Then he hid himself in a ravine through which his enemy had to pass on his way to Küssnacht, and mortally wounded him with an arrow. This event is said to have hastened the breaking out of the Swiss revolution, in which he actively participated; and he fought at the battle of Morgarten in 1315. He had reached a good old age, when, in attempting to save a boy's life, he was drowned in the Schächen. The dramatical part of this story has been questioned by modern critics; it is not narrated nor even alluded to by contemporary chroniclers, and is first found in writers of the 15th century; moreover, the name of Gessler does not figure on the records of the Austrian bailiffs. It has been remarked also that a tale to the same import was current in the ancient annals of Denmark, as appears in the *Historia Danica* of Saxo Grammaticus. (See Hisey's *Récherches critiques sur l'histoire de Guillaume Tell*, Lausanne, 1843.) Whatever the truth may be, Tell's memory is still bright in his native country; and Johannes von Müller, in his history of Switzerland, regards him as a historical character.

TELL-TALE. See **TATTLE.**

TELLURIUM (Lat. *tellus*, the earth), an elementary substance, discovered and named by Klaproth in 1798; symbol, *Te*; chemical equivalent, 64.5; specific gravity, 6.85; hardness, 2-2.5. Though commonly classed among the metals, it has much analogy in its properties to sulphur and selenium. It occurs in a native state associated with iron pyrites and various metals, as gold, silver, bismuth, copper, or lead. The native metal is of a brilliant metallic lustre, of a tin-gray or lead-gray color, passing to steel-gray. It is very fusible before the blowpipe, and burns with a bluish flame, green on the edges; it volatilizes in white fumes, leaving no residue; and it is wholly soluble in nitric acid. The substance occurs in small masses, irregularly lamellar, and crystallized in 6-sided prisms, at the mine of Maria Loretto near Zalathna in Transylvania. Tellurium is almost always combined with small portions of iron or gold in a metallic state, silver, or lead, so that some have supposed that the substance ought to be considered as a telluret of iron or of gold. Many natural alloys have been met with at the mines of Hungary and Transylvania, and from the collection of those presented by the emperor of Austria to the museum of natural history at Paris, Dufrenoy has arranged the varieties among the following 5 species: native tellurium, auro-argentiferous tellurium (graphic gold), auro-plumbiferous tellurium (mullerite), plumbo-auriferous tellurium (nag-agite), and telluric-bismuth (bornite). Auro-argentiferous tellurium was recognized at the Gold Hill mines, North Carolina, by Dr. Genth, and telluric bismuth is found in many of the gold mines of Virginia and North Carolina, in foliated scales and lamellar masses. Tellurium combines with oxygen to form two compounds of feeble acid characters, TeO , and TeO_2 , corresponding in composition with sulphurous and sulphuric acid. With hydrogen it forms the gaseous compound TeH , analogous to sulphuretted hydrogen.

TELLUS. See **TERRA.**

TEMESVÁR (anc. *Thybisus*), a town of Hungary, capital of the county of Temes, and formerly of the Banat, situated on the Bega canal, 75 m. N. N. E. from Belgrade; pop. in 1854, 20,800. It stands in an extensive marshy plain, is defended by walls and outworks, and entered by 3 gates. Iron wire, silk, cotton cloth, paper, and leather are manufactured. The Bega canal connects it with the Danube, and a railroad with Szegedin and Pesth. Temesvár is the see of both a Greek and a Roman Catholic bishop, and the seat of several law courts. It was captured after a heroic defence and sacked by the Turks in 1552, and held till 1716, when it was taken from them by Prince Eugene, and rebuilt and strongly fortified. It was besieged for about 100 days by the Hungarian revolutionary army in 1849, and was relieved by Gen. Haynau, who near its walls achieved the most important Austrian victory in that war (Aug. 9, 1849);

but it suffered severely from the bombardment, as well as from fever and cholera.

TEMPE, a valley of Greece, in the north of Thessaly, celebrated in antiquity for its beauty. It is a glen between Mts. Olympus and Ossa, through which the Peneus flows into the sea. Poets and rhetoricians often mentioned it as a type of sylvan loveliness, and it was also famed as a haunt of Apollo. It was with laurel from Tempe that the victors in the Pythian games were crowned. Only some of the later classical authors seem to have described it from observation, and to have been aware of its savage grandeur, the lofty cliffs rising almost perpendicularly on either side, and the Peneus rushing through the middle of the valley. The defile is about 5 m. in length, and is so narrow in parts as to afford space only for the river and the road. It is the only channel through which the waters of the Thessalian plain reach the sea, and was believed to have been formed by some convulsion of nature, by Hercules, or by Neptune, as an outlet for what had previously been a vast inland sea. It was also one of the few passes through which an army from the north could invade Thessaly, and was therefore of great military importance. Four carefully constructed fortresses added to its natural impregnability.

TEMPERAMENT, a term used by physiologists to express the differences in the physical and mental constitutions of individuals, referred from remote antiquity to peculiarities in the quality of the solids and fluids of the body. These peculiarities cannot be accurately estimated and defined, nor be demonstrated by the anatomist and chemist, and are detected and appreciated chiefly by the character which they impress upon the thoughts and actions, always within the limits of health. The ancients believed that the fluids of the body consisted of 4 humors (corresponding to the 4 then so called elements, earth, air, fire, and water), which they named bile, blood, black bile (supposed to come from the spleen), and phlegm or watery fluid (believed to come from the brain); and, if either of these elements was in excess, that it gave rise in the above order to the bilious or choleric, sanguine, melancholic, and phlegmatic temperaments. This view prevails in the popular mind to the present day, and was maintained by physicians to the time of Cullen, who admitted only 2 temperaments, the sanguine and the melancholic, regarding the phlegmatic as a degree of the former and the choleric of the latter. Of course, there is an endless variety in the shades of temperament in different individuals, but the characters of the 2 temperaments of Cullen are as follows: The sanguine temperament is marked by a predominance of the circulatory system, with a strong and frequent pulse, firm flesh, plump figure, smooth and fair skin, ruddy complexion, soft and light hair, and light eyes; there is great nervous susceptibility, ready memory, lively imagination, cheerfulness, and a love for sensual pleas-

ures; its diseases are generally violent and inflammatory. The English as a race are good examples of this temperament; its physical traits may be seen in the Apollo Belvedere, Venus de' Medici, Antinous, and the "Greek Slave," and its moral traits in the lives of Alcibiades, Washington, Mark Antony, Lady Jane Grey, John Adams, and Winfield Scott; and both are represented in the god Bacchus and in the celebrated duke of Richelieu. A variety of this is the muscular or athletic temperament, in which with all the external signs of strength the intellect is poorly developed; the Farnese Hercules is a good embodiment of this temperament. In Cullen's melancholic temperament, which later physiologists consider as secondary or morbid, the solids predominate, the figure being less plump and more firm, the hair and eyes black, the skin coarse and dark, the countenance sallow and sad; the vital functions are slowly performed, but the strength is considerable; the disposition is gloomy and the temper suspicious; the manner is slow, grave, cautious, impassive, but tenacious of all emotions when once excited. Don Quixote is a good representative of this temperament; also Louis XI., Tasso, Pascal, Zimmermann, and J. J. Rousseau. Other temperaments as well characterized as the above are the bilious, lymphatic, and nervous. The bilious or choleric temperament is marked by a supposed predominance of the biliary system, with strong hard pulse, yellowish brown skin and dark hair, and moderately fleshy body; by violent and easily excited passions, firmness and inflexibility of character, boldness, and perseverance. The greatest virtues and the greatest crimes are met with in persons of this temperament; here are generally placed (though in some instances erroneously, as will be seen below) Alexander the Great, Julius Cæsar, Brutus, Mohammed, Charles XII., Peter the Great, Cromwell, Cardinal Richelieu, Attila, Charlemagne, Tamerlane, Richard III., and Napoleon I. The moral faculties are early developed. It is difficult to draw the line between this and the sanguine temperament. In the phlegmatic or lymphatic temperament, the proportion of the fluids is supposed to be too great, from activity of the secreting system and inactivity of the absorbents; the flesh is soft, the skin pale and flabby, hair light, pulse weak, and the figure rounded, with little expression of countenance or activity of mind and body. Here have generally been placed Charles IV. of Spain, Augustus III. of Saxony, and Ferdinand I. of Sicily. The prominent character of the nervous temperament is a great excitability of the nervous system, and the preponderance of the emotions and impulses over the reason and will; the muscles are small and soft, and the form generally slender. Here belong fidgety and restless people, the so called creatures of impulse, and erratic men of genius; Voltaire and Frederic the Great are good examples of it. It can hardly be said to exist independently, and generally accompanies the

sanguine temperament, being best and most frequently seen in the female sex; it is often the consequence of sedentary life and of sensual indulgence and excitement; its diseases are generally hysterical and convulsive.—According to Dr. R. B. Todd, the quantity of pigment or coloring matter in the body is intimately associated with the temperaments; individuals and races of tropical and warm regions, with dark hair, eyes, and skin, belong as a rule to the melancholic temperament; while those of cold and temperate zones, with light hair and eyes and fair complexion, belong to the sanguine. Whatever physical conditions produce color and its concomitants determine also the nature of the temperament; these conditions act also to a certain extent on the mind, aiding or impeding its workings. There can be no doubt that the mind has its temperaments independent of those of the body, according as the emotions or the reasoning will vary in their natural intensity, educational development, or manner of working. The temperaments are intimately related to individual constitutions, idiosyncrasies, acquired differences, and varieties in the human race; they are more or less combined together, and by external circumstances are convertible into each other; indeed, the whole subject is so indefinite that some physiologists consider the above doctrine of the temperaments as a mere superstition connected with the old humoral pathology, and regard the mental and moral influences formerly attributed to the organic peculiarities upon which these temperaments were founded as pertaining to differences of cerebral organization.—The most recent and plausible classification of the temperaments is that originated by Dr. William Byrd Powell, and defined and illustrated in his "Journal of Human Science" (Cincinnati, O., 1860). He makes only two vital, primary, or original temperaments, the sanguine and the bilious, the latter even being only a modification of the sanguine from climatic or other external influences; to these he adds the lymphatic and encephalic (instead of the melancholic), secondary or acquired, but by transmission now become as elementary as the other two, to one or the other of which they are always adjuncta. He makes 10 compound temperaments, divided into binary, ternary, and quaternary. With the study of the temperaments, to which he has devoted nearly 40 years of his life, he has connected the very important subject of incompatible marriages; he lays it down as a physiological law that there is a sexual incompatibility in the marriage of persons who have the same or nearly allied temperaments (as he defines them), and that the children from such a union, if there be any, will die early or linger out a miserable existence. All kinds of physical degeneracy, deformity, scrofulous and cerebral diseases, he refers, and with great apparent justice, to the reduced vitality resulting from incompatible or unphysiological marriages; the union of blood

relations may be fraught with the direst consequences, not because of the blood relationship, but from the greater probability that consanguine marriages will bring together persons of incompatible temperaments; cousins will, as surely as strangers, have healthy children, provided their temperaments are compatible. Marriage in contravention to the physiological conditions known as temperaments he names physiological incest, whether with blood relations or not. The law is briefly this: one of the parties must possess exclusively a vital temperament, and the other a more or less non-vital one; and all marriages in opposition to this law are more or less incestuous; in other words, physiological incest arises from physiological and not personal or external similitude. 1. His sanguine temperament does not differ essentially from that described above; he places in it, with various adjuncts, beside Washington and Gen. Scott, Alexander the Great, Caesar, Napoleon I., Cornwallis, and Edward Everett (the last, however, with a decided encephalic adjunct). 2. In the bilious temperament the outlines of the person are angular, and the muscular movements are supple; the complexion is not necessarily dark, any more than it is of necessity florid in the sanguine; its members are apt to be impatient and impetuous; among them he places Gustavus Adolphus of Sweden, Mohammed, Dante, Pizarro, Wellington, Jefferson, and Andrew Jackson. 3. In the lymphatic temperament the head is of good size, without angularity; the person is rather shapeless, the flesh soft, the lips thick, the cheeks heavy, and the expression when at rest listless; it is compatible with excellent judgment and exalted patriotism, and is by no means necessarily the disgusting sac of humors generally represented by physiologists. This temperament is usually the result of the ease and indulgence arising from wealth, and is greatly favored by a moist atmosphere, as in China, Holland, and the deltas of the Nile and the Mississippi; it is well illustrated by the Chinese mandarins, and in the works of Rubens. The Esquimaux are bilious, not lymphatic, as often described; fat must not be confounded with lymph, the latter pervading the whole system; obesity blunts every capacity, sometimes reducing man almost to the condition of a hibernating animal, while a decidedly lymphatic person may display high mental endowments. 4. In the encephalic temperament (probably what the ancients meant by the melancholic) the cerebrum is relatively large and the cerebellum small; the person is contracted, the limbs slender, neck long, chest narrow, and abdomen flat; the face is thin, and the forehead massive and especially expanded in the upper third; the expression is severe, thoughtful, and often gloomy; the vital powers are slowly developed, and yet it is compatible with health and longevity; persons of this class are capable of profound investigation, but are very subject to monomania; of

this Pascal is an example. The last two temperaments are the results of civilization, and are not found among savage races; none of the 4 mentioned are found pure and single, or very rarely, but almost always in combination. 5. In the union of the sanguine and the bilious the hair, eyes, and complexion are light or dark according to the preponderance of each element; the head is compact, and the muscles firm and strong; Alfred the Great of England is a good example of this temperament. 6. In the sanguine-lymphatic the head is round, the face broad, the person full, and the complexion fair; the females are often beautiful, their complexion being a mixture of the lily and the rose; it is an unfavorable combination, and few who have it become celebrated for any thing good; it entails the tendency to crime, especially assassination and rowdiness; the emperor Nero may be taken as an example of it. 7. In the sanguine-encephalic the head is narrow and the forehead elevated, the skin, &c., light, the person slight, and the muscles feeble; its members are amiable, but too gentle for the rugged pursuits of life; they are generally found in the counting room and in stores, and in employments better fitted for females; some artists have been of this temperament, of which Benjamin West is an instance. 8. In the bilious-lymphatic the head is rounded, the hair, &c., dark, and the face and person full; the females are often very handsome. Persons of this temperament are good-natured, not ambitious, but useful for the soundness of their judgment. 9. The bilious encephalic is like the sanguine encephalic, except that the hair, &c., is dark; illustrations are Columbus, Shakespeare, Lord Bacon, Dr. Johnson, Pope, and Prescott the historian. 10. The first of the ternary compounds is the sanguine-bilious-lymphatic, like the sanguine-bilious, but with less plump person, thicker lips, and forehead broad below, contracting rapidly as it rises; the nose has generally a small protuberance at the end. It may possess much muscular strength and activity, many of the English prize fighters having belonged to it, and it forms a large element in mobs and riotous assemblages, whether in a good or bad cause. In this have been placed Peter the Great, C. J. Fox, Leo X., George IV. of England, Stephen Girard, Baron Larrey, and Henry Ward Beecher. 11. In the sanguine-bilious-encephalic the head is above the average size, and generally rather angular with the upper forehead expanded; it has less muscular energy than the last; many artists are of this temperament; Melancthon belonged to it, as does Gov. Banks of Massachusetts, the latter with a bilious predominance. 12. In the sanguine-encephalic-lymphatic the head is large, with elevated and expanded forehead; it has great literary capacity, but is little adapted for the sharp conflicts of life; Addison, Swift, Walter Scott, Lewis Cass, and the late Chief Justice Shaw are examples of it. 13. In the

bilious-encephalic-lymphatic the head is large, with expanded forehead, dark complexion and eyes, and full person; it is adapted for high position in any sphere of life; examples of it are Daniel Webster, the emperor Nicholas of Russia, John Bunyan, Gibbon, Prof. Agassiz, and Washington Irving. 14. The quaternary, and most gifted of all the temperaments, is the sanguine-encephalic-bilious-lymphatic; the sanguine element gives vitality, the bilious activity, the encephalic intellectual energy, and the lymphatic prevents morbid irritability; the head is large, the complexion dark, the forehead high, and the person full and round; here most probably belong Julius Cæsar, Napoleon I., Oromwell, Daniel O'Connell, and Stephen A. Douglas; it is a combination of the forces of all the elementary temperaments. All of the above temperaments are incompatible with themselves, but 1, 2, and 5 are the least so; these 3 are compatible with all the others, and one of the parties, to insure healthy progeny, should be of them or exclusively vital.

TEMPERANCE SOCIETIES. See ABSTINENCE, TOTAL.

TEMPERATURE. See CLIMATE.

TEMPLARS, or KNIGHTS OF THE TEMPLE, the most celebrated and powerful of the religious military orders of Christendom. Its origin is ascribed to Hugues de Payens, Geoffroi de St. Omer, and 7 other French knights, who in 1118 or 1119, in addition to the 8 vows of chastity, poverty, and obedience, took a 4th, by which they bound themselves to defend the holy sepulchre of Christ and to afford protection to the numerous pilgrims who then annually flocked to the Holy Land. The military character associated with the new order attracted immediate attention, and after its formal incorporation by Pope Honorius II. in 1128 at the instigation of St. Bernard, its numbers rapidly increased, members of the noblest families of Europe seeking admission into its ranks, and people of every degree vying with each other in endowing it with gifts of land or money. In 1128 the templars also received from Honorius a peculiar dress consisting of a white mantle, to distinguish them from the hospitallers, who were habited in black; and in 1146 they added a red cross on the left breast. This emblem was also borne on their banner, formed of striped black and white cloth, and called *déauçant*, a word rendered famous throughout Christendom as the battle cry of the order. Soon after their establishment Baldwin II., king of Jerusalem, gave them a part of his palace as a residence, to which the canons of the adjoining convent of the temple added another building for keeping their arms, whence they were called knights of the temple. After the order had acquired power and possessions throughout Europe and the East, it came under the control of a complex form of government, consisting of a grand master or head of the order, elected by the chapter or general body of the knights, and

who had under him a seneschal and other high officers; provincial masters, who presided over the several countries or provinces in which the templars had possessions; priors or masters, who had charge of the districts into which a province was divided; and preceptors or superintendents of the single houses of the order in the districts. The province in which the grand master resided, and which for upward of 173 years from the foundation of the order continued to be in Palestine, was always considered the chief seat of the order, and its chapter had the powers of a general chapter when that body was not in session. Of the 2,000 lordships and estates which the order possessed in the middle of the 13th century, the chief part were in France, and to that country generally belonged the grand master, who in some respects assumed the dignity of a sovereign prince. For more than 40 years after their organization the templars comprehended only laymen; but by a bull of 1172 Pope Alexander III. allowed the order to receive spiritual members, who celebrated mass and other religious offices in its houses, acted as secretaries to the chapter, or filled the office of preceptor. Somewhat later persons not of noble birth or knightly rank were admitted as servitors or serving brethren, of whom there were two classes, those who attended the knights in the field in the capacity of squires, and those who exercised various handicrafts in the preceptories, the former being held in the greater estimation. There were also affiliated members, who took none of the vows and assumed none of the duties of the order, but sought even a qualified admission into its ranks for the security thereby afforded; and lastly children dedicated by their parents to the order, and hence called *donati*, and persons who under the name of *oblats* pledged themselves to maintain its rights. Among other important advantages conferred upon the templars was that of having the offices of religion performed in their houses once a year, even in countries under an interdict, whence in practice they became exempt from the effects of an interdict, a circumstance which added greatly to their influence and numbers. They became in time a formidable and wealthy military community, the members of which, animated by the closest corporate spirit and subjected to the severest internal discipline, had no property or interest distinct from the order in general, acknowledged no spiritual authority but the pope, and held themselves amenable to him only in secular matters. Originally subsisting upon the alms of the charitable and making a show of poverty, as illustrated by their seal, which represented two knights riding upon a single horse, they increased so rapidly in wealth as to become more interested in extending and guarding their possessions than in affording protection to pilgrims; and notwithstanding their unquestioned prowess and daring, their frequent feuds with the rival order of the hospitallers, and

their open licentiousness and lust of gain, often injured rather than aided the cause to which they had devoted themselves. Hence they fought more for themselves than for the common cause of Christianity, aided or thwarted the plans of campaigns at their pleasure, and frequently stained their knightly name and fame by open treachery, as in the 6th crusade under the emperor Frederic II., the partial failure of which was attributed to the machinations of the templars. So far had they departed from the motives and principles of the founders of the order, that during the gradual decline of the Christian kingdom in Palestine they endeavored by separate treaties with the Saracens to secure their own possessions in that country. After having their chief seat successively in Jerusalem (1118-'87); Antioch (1187-'91), Acre (1191-1217), and the Pilgrim's Castle near Ossaesa (1217-'91), they were nevertheless compelled at the final extinction of the Latin power in Palestine in 1291 to remove to the island of Cyprus, which they had purchased from Richard I. of England for 35,000 silver marks. Though driven out of the Holy Land, the organization evinced no signs of decay, and its extensive ramification throughout Europe drew upon it the suspicion and jealousy of princes, whose cupidity was also excited by its immense wealth in landed revenues and hoarded coin. Under the influence of these motives, and irritated by his inability to tax the order, Philip the Fair of France, in concert with Pope Clement V., determined upon its destruction. Accordingly, in 1306 Jacques de Molay, the grand master of the templars, was enticed to Paris, on a pretext of consulting him with reference to a new crusade and other matters; and on Oct. 18, 1307, all the members of the order in France, including De Molay himself, were taken into custody, and their houses and goods were everywhere seized. The formal charges on which they were arrested, and which were preferred by two degraded templars, imputed to them grave heresies connected with their secret rites of initiation and internal discipline, and graver violations of morality. How far the influence of oriental manners and superstitions may have affected the belief or habits of the order during their long residence in Palestine, it is difficult to determine; but although it is not improbable that they had borrowed to some extent from the Gnostic rites and magical practices of the eastern races with whom they had come in contact, there is no evidence beyond their own confessions, wrung from them by torture, to substantiate the charges of their accusers. Under these circumstances the pope hesitated to promulgate the decree for the extinction of the order; but the less scrupulous Philip, finding his colleague loath to imitate his own intemperate zeal, procured one of his creatures, the archbishop of Sens, whose jurisdiction extended over Paris, to convoke his provincial council in that city on May 10, 1310; and on the

18th of the month, by command of that body, 54 members of the order were burned at the stake in a field behind the abbey of St. Antoine. The example was imitated elsewhere, and on May 2, 1312, Clement on his own responsibility, the general council of Vienne then in session being averse to precipitate measures, issued a bull for the abolition of the templars. Their movable property was for the most part appropriated by the sovereigns of the countries in which it was deposited; and although their landed possessions were nominally transferred to the hospitalars, the crown as a general thing secured the disposition of them. The order ceased at once throughout Christendom except in Portugal, where it merely assumed the name of the chevaliers of Christ, which order still subsists. The last act of the drama was the execution at the stake of De Molay, Guy of Auvergne, and other high dignitaries of the order, of whom the two first named died protesting their innocence, having previously recanted the confessions extorted from them by hopes of absolution or by torture.

TEMPLE, RICHARD GRENVILLE, earl, an English statesman, born in 1711, died in 1777. He was the eldest son of Richard Grenville and Hester Temple, and in 1752 succeeded his mother, who had in 1749 been created Countess Temple, as Earl Temple. The marriage of his sister Hester Grenville with William Pitt, afterward earl of Chatham, was the means of introducing him to public life, and during the first Pitt administration he was a prominent member of the cabinet. According to Macaulay, he was not remarkable for administrative talents, but was a skilful parliamentary tactician. In 1852-'8 appeared "The Grenville Papers" (4 vols. 8vo.), comprising the correspondence of Earl Temple and his brother George Grenville between 1743 and 1777, edited by W. J. Smith from the original papers deposited at Stowe, the chief seat of the family. They throw much light upon the political movements of the period which they cover, and are asserted by the editor to afford evidence of the identity of Earl Temple with Junius. The present representative of the Grenvilles is the duke of Buckingham and Chandos.

TEMPLE, SIR WILLIAM, an English statesman and author, born in London in 1628, died at Moor Park, Surrey, Jan. 27, 1699. He was the son of Sir John Temple, master of the rolls in Ireland. He passed two years at Emmanuel college, Cambridge, went abroad without taking a degree, and after a somewhat extended continental tour, in the course of which he acquired a mastery of the French and Spanish languages, he returned to England, was married in 1654, and for several years resided with his father in Ireland. In 1660 he was chosen a member of the Irish convention for the county of Carlow, and also represented that constituency in the first Irish parliament convoked after the restoration. In 1668 he repaired to England with his family, carrying letters of recommendation

from the duke of Ormond to Lord Arlington, one of the secretaries of state, and in 1665 was sent by that minister on a secret mission to the bishop of Münster, who had stipulated, in consideration of the payment by the English government of a large subsidy, to make a land attack upon the Dutch, who were then at war with England. Although the bishop deserted his allies and made a separate treaty with the Dutch, Temple's diplomatic services were so highly esteemed by Charles II. that he was created a baronet and appointed resident at Brussels. In the autumn of 1667, soon after the conclusion of peace with Holland, Temple made a visit incognito to that country, and, in view of the dangerous encroachments of France upon the Spanish Netherlands, urged upon his government the necessity of an offensive and defensive league with Holland against the projects of Louis XIV. Receiving, in Jan. 1668, the necessary powers to negotiate such a treaty, he concluded in the same month the celebrated triple alliance between England, Holland, and Sweden, by which the contracting parties bound themselves to endeavor to bring about a peace between France and Spain, and to keep the former power out of the Low Countries. This measure, characterized by Macaulay as "the single eminently good act performed by the government during the interval between the restoration and the revolution," gave Temple at once a European reputation, and is considered the master stroke of his political career. After perfecting at Aix la Chapelle negotiations for peace in pursuance of the triple alliance, he repaired in Aug. 1668, in the capacity of ambassador, to the Hague, where he cultivated a warm friendship with the grand pensionary De Witt and the young prince of Orange. Recalled to England in Sept. 1670, he discovered that the ministry had treacherously formed a secret treaty with France, by which the triple alliance was rendered of no effect, and in June, 1671, received his dismissal from office. For two or three years he resided at his estate of Sheen; but in 1674 he was summoned from his retirement to negotiate a peace with Holland, which he accomplished in London in the space of 8 days. He returned soon afterward to his former position at the Hague, and was also one of the mediators deputed to attend the congress of Nimeguen, which after tedious negotiations resulted, in the latter part of 1678, in a hollow and unsatisfactory treaty of peace between France and Holland, to which Temple declined to affix his signature. In the interval he contributed largely to bring about the marriage of the prince of Orange with Lady Mary, daughter of the duke of York. Returning to England in 1679, he was solicited by the king to accept the office of secretary of state, which had indeed been offered to him before; but feeling, to use his own words, that "the scene was unfit for such an actor as he knew himself to be," he excused himself on the score of not having a seat in parliament. The king, harassed

by the violence of parliament, gladly availed himself of the advice of Temple, whose plan for a new privy council of 80 members, 15 to be great officers of state and 15 independent noblemen and gentlemen of great weight and landed possessions, was in April, 1679, carried into effect, to the great satisfaction of the public. Almost immediately afterward one of the fundamental principles on which it had been constructed, the prohibition of a secret interior council or cabinet, was violated; Lord Shaftesbury was admitted a member against the remonstrance of Temple; and in general the objects of the projector were so perverted, that he gradually ceased to attend the regular meetings. A single session of parliament, to which he had been elected from the university of Cambridge, sufficed to satisfy him with legislative life; and upon his name being stricken by the king from the list of privy councillors, he gladly retired in 1680 to his gardening and library at Sheen. Thenceforth he lived in retirement, either at Sheen or at Moor Park, a seat in Surrey, engaged in the completion of his memoirs, and enjoying the confidence and friendship of William III., who vainly urged him in 1688 to accept the secretaryship of state, and who frequently visited him for advice in public matters. During the last 10 years of his life he was attended in the capacity of secretary by Jonathan Swift. His works, comprising "Observations upon the United Provinces of the Netherlands," essays on the "Origin and Nature of Government," "Ancient and Modern Learning," "Gardening," &c., and a variety of political and miscellaneous tracts, contain many acute observations, expressed in so easy a style that he is called by Johnson "the first writer who gave cadence to English prose." Sir James Mackintosh calls him "the model of a negotiator;" but according to Macaulay "he was merely a man of lively parts and quick observation; a man of the world among men of letters; a man of letters among men of the world." As a fine gentleman he was one of the most distinguished of the age. His collected works were first published in 1720; the last and best edition is in 4 vols. 8vo. (London, 1814).

TENANT. See LEASE, and TENURE.

TENASSERIM PROVINCES, a tract of land in British India beyond the Ganges, attached to the government of Penang, under the Bengal presidency, extending about 500 m. along the E. side of the bay of Bengal, with a breadth of from 40 to 80 m., between lat. 11° and 19° N. and long. 97° 30' and 99° E., bounded N. by the native state of Laos, E. and S. by Siam and the Malay peninsula, and W. by the bay of Bengal gulf of Martaban, and Pegu, from the last of which it is separated by the river Salwin; area, 30,000 sq. m.; pop. estimated at 200,000. The country is divided into the provinces of Amherst, Tavoy, Ye, and Mergui; and the chief towns are Amherst, the capital, Maulmain, Martaban, Tavoy, Mergui, and Tenasserim. The sea coast S. of lat. 11° 40' is bold and rocky, while to the N.

it is flat and much more indented with bays, creeks, and the estuaries of rivers and streams. Along its whole extent are situated islands which appear from seaward to form part of the shore. Those lying between lat. 8° and 14° 40' N. are known collectively under the name of the Mergui archipelago, and extend from 30 to 80 m. from the shore. The principal islands of this group, from S. to N., are Sullivan island, Kisseraing, Domel, Kalegouk or Bentinck, Ross, King's, and Tavoy. The most important island on the coast, however, is Balugyun, opposite the town of Maulmain, 17 m. long and 8 broad.—The whole territory of Tenasserim, particularly toward the N., is intersected by numerous rivers, the principal being the Salwin, Atta-Yen, Tavoy, and Tenasserim. The E. boundary is formed by a range of wooded mountains varying in height from 3,000 to 4,000 feet above the sea. In the N. there is a separate range, about 2,000 feet high, covered with bamboo jungles. There are extensive plains and fertile valleys lying upon the banks of the rivers toward the N. The staple productions are rice, cotton, sugar cane, indigo, and tobacco; and wheat, nutmegs, different spices, and dye stuffs are raised. Nearly 880 different varieties of timber have been enumerated. Iron ore is very abundant, and exceedingly rich. Tin, gold, copper, bismuth, antimony, and manganese are also found. Coal of good quality has been discovered in several places. The climate is considered remarkably healthy, the rate of mortality among Europeans being little more than it is in Europe in like circumstances. The thermometer never rises above 90°, the average being 77°. The rainy season begins in the S. part of the territory about the 1st of May, and at Maulmain a month later; the fall is much the greater toward the N., where it is estimated at 200 inches in a year.—The population comprises Burmese, Peguans, Siamese, Karens, Seelongs, Hindoos from the Coromandel coast, half caste Portuguese, Chinese, a few American missionaries, and the English officials and traders. The Burmese and Peguans are the most numerous; and the Siamese are principally settled in the neighborhood of the Tenasserim river. The chief manufactures are cotton and silk goods, coarse pottery, and iron cooking vessels. Ship building is largely carried on at Maulmain, and to a less extent at Mergui and Tavoy. The chief exports consist of rice, tobacco, gambier, ivory, edible birds' nests, and teak timber.—The Portuguese visited the territory which forms the Tenasserim provinces early in the 17th century; and in 1687 some English were massacred at Mergui, the country being then a dependency of Pegu. It afterward became subject to Siam, from which power it was taken about the middle of the last century by the Burmese, who held it till it was annexed to British India at the termination of the Burmese war in 1826. From the long unsettled state of the country, the entire population of the 4 provinces at that time only amounted to

about 80,000; but since security for life and property has been established population has rapidly flowed in from the surrounding states.

TENCOH, a soft-rayed, fresh water fish of the carp family, and genus *tinca* (Cuv.), peculiar to the old world. The best known species is the *T. vulgaris* (Cuv.), rarely more than 14 inches long, of a deep yellowish brown color, and sometimes golden and greenish; the dorsal and anal fins have no osseous rays, and the former is inserted behind the commencement of the ventrals; the teeth on the pharynx are compressed and club-shaped; scales very minute, covered with mucus; a very small labial barbel at each side of mouth; the body thick and broad, and the ventrals in the male much larger than in the female. It is spread over Europe and N. Asia, and is more or less abundant in the ornamental waters and ponds of Great Britain, but is not found much above lat. 60° N.; it prefers stagnant waters with a muddy bottom, concealing itself in winter in the mud in a torpid state; like the carp it is very tenacious of life; the food consists of worms and aquatic insects, with sometimes seeds and plants. The eggs are deposited in May or June; they are very minute, of a greenish color, about 800,000 in a single female, and are placed among aquatic plants. In its natural state the flesh is apt to be soft, insipid, or ill-flavored, and difficult of digestion; but it is said to be very delicate when the fish are properly fed.

TENCOIN, CLAUDINE ALEXANDRINE GUÉRIN DE, a French courtesan and novelist, born in Grenoble in 1681, died in Paris, Dec. 4, 1749. Yielding to the wishes of her family, she became a nun; but, struggling to free herself from her vows, she first succeeded in being transferred as canoness to the chapter of Neuville, near Lyons, where she enjoyed much more liberty, and finally in 1714 obtained her complete secularization. She repaired to Paris, and became first the mistress of the duke of Orleans, and then of the abbé Dubois, who gave her a splendid house. She advanced the fortune of her brother, afterward Cardinal de Tencin and minister of state under Fleury, to whom she was passionately attached, while gaining for herself wealth through her connection with the financier John Law, and fame through her intercourse with Fontenelle, Montesquieu, and other literary characters, whom she entertained at her house and playfully styled her "beasts" or "menagerie." By Destouches-Canon, one of her numerous lovers, she had a child who was abandoned at the porch of the church of St. Jean le Rond, and became afterward the celebrated D'Alembert. In April, 1726, another, La Fresnais, a councillor in the parliament, in a fit of despair killed himself at her house, and in his will accused her of being his destroyer. She was consequently incarcerated in the Bastille; but the charge was proved to be unfounded, and she was released in the beginning of July. She now became more discreet, lived more than ever among the society of wits

and gentlemen, made her parlor a school for refined taste and elegance, exchanged letters with Cardinal Lambertini, afterward Benedict XIV., who after his accession sent her his likeness, and wrote novels, which are remarkable for observation, good taste, and perspicuity.

TENDER, in law, an offer to perform an act, to the performance whereof one person is bound to another. The obligation, and so the offer, may be to pay money or to deliver specific articles. If the tender be of money, it is effectual only when the demand is one of money, and is definite in amount, or is capable of being made so. Thus, a tender cannot be pleaded as a defence to an action for general damages upon a contract, nor to an action in covenant, unless the contract be one for the payment of money, as for rent; nor to an action for a tort, as for assault and battery. In short, wherever the claim is for unliquidated damages, the general rule is that no tender is admissible. In the United States, however, cases of involuntary trespass form an exception, founded partly on usage and partly on express statutory provisions.—A tender need not be made by the defendant personally. If made by a third person at his request, it is sufficient; and even if made by a stranger without his knowledge or request, it seems that a subsequent assent of the debtor will operate as a ratification of the agency and make the tender good. Any person may make a valid tender for an idiot. Tender must be made to the creditor personally, or to some one authorized by him to receive the money. Tender to the creditor's attorney, authorized by him to collect the claim, is usually sufficient; and in such a case the tender need not include the amount of the attorney's fee for his letter to the debtor.—At common law, a tender must be made on the very day the money is due, if that day be made certain by the contract. But the statutes and usages of the states generally permit the tender to be made after that day, if before the action is brought; and in some it may be made after the action is brought. Tender is generally not good if made before the debt is due, but may in some cases be so if it includes interest up to the day of maturity.—A tender of money is not complete without production and offer of the money, unless the creditor expressly or impliedly waives the production. Thus it is said not to be enough in a plea of tender, if the plaintiff did not object to receive the money, for the defendant to prove that he had the money in his pocket, and said to the creditor that he had it ready for him, and asked him to take it. He ought to have produced and offered the money specifically. What amounts to a waiver on the part of the creditor is a nice if not difficult question. It seems from the cases that the creditor may not only waive the actual production of the money, but the actual possession of it in hand by the debtor. The debtor is not bound to count out the

money if he has it and offers it.—The tender must be made without any condition that the creditor may with good reason object to. A demand of a receipt in full of all demands has often been held to invalidate a tender; not so much, however, because a receipt was asked for, as because part was offered in full payment. And it seems that a debtor would lose the benefit of a tender if he should accompany it with a demand of a receipt for the sum that he pays, and because it was refused should retain the money. Tender of a larger sum than is due, with a request of the change or the balance, is not good. Thus the offer of a \$5 bill, with a demand of the change, is not a good tender of \$4. Refusal of the money offered, for reasons distinct from the manner in which the offer is made, as for the insufficiency of the sum or the like, is a waiver of all objection to the form of the tender. The tender should be made in lawful coin of the United States, or in money made lawful by the state in which it is offered. A tender of good and current bank notes is good if no objection is made on the ground that they are not money.—As tender means not only that the debtor was once ready and willing to pay, but that he has always been so and still is, the effect of it will be destroyed if the creditor can show a subsequent demand by him of the proper fulfilment of the contract at the proper time, and a refusal by the debtor. Some authorities have held that a demand and refusal may in some cases have the effect of annulling a tender even if they take place before the tender was made; although generally, if not universally in the United States, a tender is valid and effectual if made at any time after a debt is due.—Tender does not bar a debt as payment would, but rather establishes the liability of the defendant; for, in general, he is liable to pay the sum which he tenders whenever he is required to do so. But the tender stops the recovery of damages or interest for delay in payment, and gives the defendant subsequent costs, provided the plaintiff recovers nothing beyond the sum tendered.—It may be regarded as settled that acts which would constitute a sufficient tender of money will not always have this effect in relation to chattels. Thus, if one who is bound to pay money to another at a certain time and place, is there with the money in his pocket for the purpose of paying it, and is prevented from doing so only by the absence of the payee, this has the full effect of a tender. But if he is bound to deliver chattels at a particular time and place, it may not be enough that he has them there; they may be mingled with others of the like kind which he is not to deliver, or they may need some act of separation, identification, or completion, before they can become the property of the other party. As in sales the property in chattels does not pass while any such act remains to be done, so if there be an obligation to deliver those articles, it may be said as a general rule that the obligation is

not discharged so long as any thing is left undone which would prevent the property from passing under a sale. If one bound to deliver 20 bushels of wheat at a certain time and place, came there with 50 bushels in his wagon, all of the same quality, and in one mass, with the purpose of measuring out 20 bushels, and was prevented from doing so only by the absence of the promisee, this would probably be held as a sufficient tender. The tender of goods may be made to an agent or by an agent, and must be equally unconditional as if of money; and if the agent of the deliverer has orders to deliver the chattels to the receiver only if he will cancel and deliver up the contract, this is not a tender, although the agent had the chattels at the proper time and place.—Generally, if no time or place be specified, the articles are to be delivered where they were at the time of the contract, unless collateral circumstances designate a different place. If the time be fixed, but not the place, it will be presumed that the deliverer was to bring the articles to the receiver at that time; and for that purpose he must go with the chattels to the residence of the receiver, unless something in their very nature or use, or some other circumstance of equivalent force, distinctly implies that they are to be left at some other place. And it may happen from the cumbersomeness of the articles, or other circumstances, that it is obviously reasonable and just for the deliverer to ascertain from the receiver, long enough beforehand, where they shall be delivered; and then he will be held to this as a legal obligation. If the receiver refuses or neglects to appoint a place, or purposely avoids receiving notice of a place, the deliverer may appoint any place with a reasonable regard to the convenience of the other party, and there deliver the articles. If no expressions used by the parties and nothing in the nature of the goods or the circumstances of the case control the presumption, then the place where the promise is made is the place where it should be performed; and no action can be maintained upon such a promise unless the plaintiff can show a demand at the proper place and time, or a readiness to receive, and notice equivalent to a demand, or else that the demand would have been nugatory because the defendant could not have complied with it. If by the terms of the contract specific articles are to be delivered at a certain time and place in payment of an existing debt, this contract is fully discharged and the debt is paid by a complete and legal tender of the articles at the time and place, although the promisee was not there to receive them; and no action can be thereafter maintained on the contract. But the property in the goods has passed to the creditor, and he may retain them as his own, or take them elsewhere; or he may demand them, and if they are refused bring an action for them as his own.

TENDON, the firm fibrous bundle or cord, the continuation of the intermuscular areolar

tissue, by which a muscle is ordinarily attached to bone. Tendons are of a shining white color, dense and inextensible, flattened or rounded, and more or less elongated; when very much flattened and membranous, they are called *aponeuroses* and sometimes *fascia*. They glide smoothly in sheaths, especially in the extremities, and on the surface of flexion of the limbs; in some cases many are enveloped in a single sheath, in others they are kept in place by an annular ligament, as in the wrist and ankle. One of the most important is the *tendo Achillis*, by which the muscles of the calf are attached to the heel bone, so named from Achilles having received his death wound there from Paris during the siege of Troy; it is often contracted, as in the various forms of club foot, and is frequently divided to enable the foot to be brought down by extension apparatus. Contractions of the tendons of the fingers and toes, and of the elbow and ham, are frequently remedied by the same subcutaneous method of tenotomy; *torticollis* or wry neck is also benefited by the division of the tendon of the sternomastoid muscle. One of the most beautiful contrivances and evidences of design in the human body is the manner in which the superficial flexor tendons in the fingers stop short at the middle phalanx, and divide to allow the tendons of the deep flexor to pass through to the terminal phalanx, thus securing compactness and beauty of shape, with freedom and extent of motion.

TENEDOS (in earliest antiquity *Calydna*, *Leucophrys*, *Phœnice*, and *Lyrnessus*), a small island in the Ægean sea or Grecian archipelago, now belonging to Turkey, about 12 m. from the mouth of the Hellespont or Dardanelles, and 4 m. W. from the coast of Asia Minor. It is about 5 m. long by 2 broad, and owes its chief importance to its position. In the legend of the Trojan war it is mentioned as the place to which the Greeks withdrew after leaving the wooden horse before Troy, and it was employed in the Persian war by Xerxes as a naval station. Subsequently, on several occasions, as in the Peloponnesian, Macedonian, and Mithridatic wars, it figured conspicuously as a stronghold.

TENERANI, **PIETRO**, an Italian sculptor, born in Torano, near Carrara, in the latter part of the 18th century. After studying a while under his uncle Pietro Marchetti and in the academy of Carrara, he established himself in 1814 in Rome, and finished his art education in the studio of Thorwaldsen. His "*Psyche with the Box of Pandora*" (1819), now in the Lenzi palace, Florence, was succeeded by numerous works illustrating both Christian and classical mythological subjects. Of his religious works, the most remarkable are "*Christ on the Cross*," in silver, in the church of San Steffano, Pisa; the "*Descent from the Cross*," in the Torlonia chapel of the church of St. John Lateran, Rome; the martyrdom of Eudorus, &c.; beside a number of statues of saints and monu-

mental works. Of the latter class, the "Angel of the Last Judgment," in the church of Sta. Maria in Rome, is a characteristic specimen. Among his classical subjects may be enumerated the "Swooning Psyche," the "Faun playing on a Flute," the "Flora," in the possession of the queen of England, and the "Cupid extracting a Thorn from the Foot of Venus," of several of which he has executed duplicates. His statues of public characters include those of Leuchtenberg and Orloff at St. Petersburg, of Ferdinand II. and III. of Naples, of Bolivar, and of Count Rossi, who was killed in Rome in 1848. His portrait busts are also numerous, those of Thorwaldsen and Pius IX. being among the best. He is professor of sculpture in the academy of St. Luke, Rome.

TENERIFFE (Sp. *Tenerife*), the principal island of the Canary group, 90 m. N. W. from Cape Bojador on the African coast, between lat. 28° and 28° 36' N., and long. 16° 5' and 16° 55' W.; extreme length 60 m., breadth 20 m.; area, about 1,000 sq. m.; pop. 85,000. The coast is very irregular, and is formed of an uninterrupted succession of lofty cliffs penetrated by a few narrow ravines. The only good harbor is that of Santa Cruz, the chief town, upon the N. E. side, which is protected by two rocky points enclosing a semi-circular bay. Teneriffe is wholly of volcanic formation, and is composed of masses of trachyte, lava, and basalt. The peak of Teyde, toward the N. W. of the island, attains the height of 12,205 feet above the sea. The crater is situated at the summit, and is about 1 m. in diameter; but the eruptions which have happened during the last 8,000 or 4,000 years appear to have been made through the sides. There are 5 other craters, one of them much larger. Since the island was occupied by the Spaniards in 1496 only two eruptions have taken place, one in 1706 and the last in 1798; but clouds of vapor frequently ascend from the craters. Along the base of the great mountain and for some distance up its sides there are villages, fields, gardens, and vineyards, next to which succeeds a tract of forest, and beyond that is a barren plain covered with blocks of lava and pumice stone. The N. E. part of Teneriffe is the most fertile, but only about $\frac{1}{4}$ of the whole surface is arable. The chief productions are cochineal, wine, silk, maize, wheat, oranges, potatoes, pulse, almonds, honey, wax, &c.

TENIERS, DAVID, called the elder, a Flemish painter, born in Antwerp in 1582, died there in 1649. He was educated in the school of Rubens, and subsequently studied in Italy, where he acquired from his countryman Adam Elsheimer a taste for cabinet pictures, to which he exclusively devoted himself after his return to Antwerp. His favorite subjects were rural sports and merrymakings, alehouse interiors, chemists' laboratories, and grotesque subjects, such as the temptation of St. Anthony, all of which he treated with great humor and fidelity to nature. He was greatly distinguished as a

colorist, and his pictures commanded during his lifetime large prices.—DAVID, the younger, born in Antwerp in 1610, died in Brussels in 1690 or 1694. He has been said on doubtful authority to have studied under Rubens, Adrian Brauer, and Elsheimer, but probably received most of his instruction from his father. The archduke Leopold, then governor of the Spanish Netherlands, having appointed him his principal painter, with the superintendence of his gallery of Italian and Flemish masters in Brussels, he soon rose to the head of his profession. He was distinguished by a talent for imitating the works of others, and executed views of the interior of the grand duke's gallery, representing the walls with the pictures on them, and faithfully giving the style of each painter. He also painted a number of ingenious compositions of his own in the style of Tintoretto, Paul Veronese, Bassano, Rubens, and others. His authentic works amount to upward of 1,000, and bring prices varying from 800 to 1,500 and 2,000 guineas. There are also about 500 spurious pictures attributed to him. Some of his pictures are of great size, one at Schleissheim, 18 feet 6 inches by 10 feet, containing 1,188 figures, of which those in the foreground are 12 inches in height. He worked with great rapidity, and some of his thinly painted pictures are said to have been begun and finished at a single sitting.

TENISON, THOMAS, an English prelate, born in Cottenham, Cambridgeshire, Sept. 29, 1636, died Dec. 14, 1715. He was graduated at Corpus Christi college, Cambridge, in 1657, and began to study medicine, but in 1659 was privately ordained. After the restoration he was appointed to St. Andrew's church, Cambridge, and in 1680 was presented by Charles II. to the living of St. Martin's in the Fields, where he endowed a free school, and built and furnished a library. William III. made him archdeacon of London in 1689, bishop of Lincoln in 1691, and archbishop of Canterbury in 1694, on the death of Dr. Tillotson.

TENNANT, WILLIAM, a Scottish poet and orientalist, born in Easter Anstruther, Fife-shire, in 1785, died near Dollar, Feb. 15, 1848. He was educated at the university of St. Andrew's; but, debarred from active employment by having lost at an early age the use of his feet, he became in 1801 clerk to his brother, a corn factor of Glasgow, and in this situation studied zealously and unaided the modern languages and Hebrew. Returning to Anstruther, he published in 1812 "Anster Fair," a humorous poem in the *ottava rima*, which received high praise from Jeffrey in the "Edinburgh Review," and passed through many editions. In 1818 he became parish schoolmaster of Dunnino, and while teaching there made himself master of the Arabic, Syriac, and Persian languages. In 1816 he taught at Lasswade, and in 1819 went to Dollar academy, where he acted as instructor of the classical and oriental languages until 1835, when he was made pro-

fessor of oriental languages in St. Mary's college, St. Andrew's. Here he compiled Syriac and Chaldaic grammars, which appeared in 1840. Beside writing some miscellaneous poems and translations from the Persian, Greek, and German, he published "The Thane of Fife" (1822); "Cardinal Beaton" (1828), a tragedy; "John Baliol" (1825), a drama; "The Dying Down of the Cathedral" (of St. Andrew's); "Hebrew Dramas founded on Bible History" (1845); and a "Life of Allan Ramsay" was first issued in New York (1858).

TENNEMANN, WILHELM GOTTLIEB, a German historian of philosophy, born at Brembach, near Erfurt, Dec. 7, 1761, died in Marburg, Sept. 30, 1819. He studied at Erfurt, where he abandoned theology for philosophy, and at Jena, where he was both one of the first opponents and one of the first adherents of the Kantian system. He became professor extraordinary of philosophy at Jena in 1798, and at Marburg in 1804, and retained the latter position till his death. His most important work is the *Geschichte der Philosophie* (11 vols., Leipsic, 1798-1819), in which all systems are regarded from the standpoint of the critical school. An abridgment, entitled *Grundriss der Geschichte der Philosophie* (Leipsic, 1819), has been translated into English by Arthur Johnson (1862; revised by J. R. Morell, 1858). Among his other publications are: *Lehren und Meinungen der Sokratischer über Unsterblichkeit der Seele* (Jena, 1791); *System der Platonischen Philosophie* (4 vols., Leipsic, 1792-4); and translations from German from Locke, Hume, and De Gerando.

TENNENT, GILBERT, an American clergyman, born in the county of Armagh, Ireland, Feb. 5, 1703, died in Philadelphia, July 28, 1764. He was the son of the Rev. William Tennent, an Irish Presbyterian clergyman who emigrated to America in 1718, and several of whose sons and grandsons entered the ministry. He was ordained in 1726 at New Brunswick, N. J., and remained there as pastor till 1748, though he spent several months with Whitefield on a preaching tour in New England, where his eloquence and terrible descriptions of the eternal punishment due the sinner produced a great effect. In 1741 he was instrumental, by his fiery denunciations of those who differed from him in doctrine, in causing a division in the Presbyterian church, which 17 years later he did his utmost to heal. In 1748 he was called to the charge of a Presbyterian church in Philadelphia, where he resided during the remainder of his life, excepting a visit to England in 1758, in company with the Rev. Samuel Davies, to solicit aid for the college of New Jersey. He published many works, but few of permanent interest.—WILLIAM, an American clergyman, brother of the preceding, born in the county of Antrim, Ireland, Jan. 3, 1705, died at Freehold, N. J., March 8, 1777. When he had nearly completed his theological course, he became seriously ill, fell into a catalepsy or

trance, and remained for several days in a condition of apparent death. His physician, perceiving a slight tremor under his left arm, refused to consent to his burial; and, although his friends were satisfied that he was dead, his funeral was postponed for 8 days, and subsequently for several hours, efforts being made for his resuscitation, which finally occurred just as his physician was giving up in despair. His recovery was very slow and painful, and for many months his memory and intellectual faculties were almost lost, but were eventually and suddenly restored. Mr. Tennent's own account of his emotions during this period was, that at the moment of his apparent decease he found himself surrounded by an unutterable glory, and saw a great multitude, apparently in the height of bliss, singing most melodiously; and that when he was about to join the great and happy multitude, some one came to him, looked him full in the face, and said: "You must go back." At the shock this intelligence gave him he opened his eyes, and, finding himself in the world, fainted. For 8 years he said the recollection of what he had seen and heard was so intense as to make earthly things seem worthless. Mr. Tennent was ordained in 1788 at Freehold, Monmouth co., N. J., where he continued as pastor 44 years. He published only a few occasional sermons. A memoir of him, giving a very full account of his trance, was prepared and published by Judge Elias Boudinot.

TENNENT, SIR JAMES EMERSON, a British author and statesman, born in Belfast, April 7, 1804. His name was originally Emerson, Tennent being added on the succession of his wife to the estate of her father, William Tennent. He was educated at Trinity college, Dublin, and was called to the bar at Lincoln's Inn in 1831, but never practised. Under the name of Emerson he published "Travels in Greece" (1825); "Letters from the *Ægean*" (2 vols., 1829); and "History of Modern Greece" (2 vols., 1880). In 1832 he was elected to parliament for Belfast, and continued to represent that city most of the time till 1845. From 1841 to 1845 he was secretary to the India board; in 1845 he was appointed civil secretary to the colonial government of Ceylon, and knighted. He returned in 1850, and in 1852 was member of parliament for Lisburn, and for a few months of that year secretary of the poor law board. In Nov. 1852, he became one of the joint secretaries of the board of trade, which office he still holds. He is also deputy lieutenant of the county of Sligo, and a magistrate for Antrim and Down. His works, beside those already mentioned, are: "Belgium" (2 vols., 1841); "A Treatise on the Copyright of Designs for Printed Fabrics, &c." (1841); "Christianity in Ceylon, with an Historical Sketch of the Brahminical and Buddhist Superstitions" (8vo., 1850); "Wine, its Use and Taxation" (8vo., 1855); "Account of Ceylon" (2 vols., 1859); and "Sketches of the Natural History of Ceylon" (1861).

TENNESSEE, one of the southern states of the American Union, and the third admitted under the federal constitution, situated between lat. 35° and 36° 30' N., and long. 81° 37' and 90° 28' W.; greatest length from E. to W. about 430 m., breadth 105 m.; area, about 45,600 sq. m., or 29,884,000 acres. Its shape is rhomboidal, its E. and W. sides sloping at considerable, though not equal angles. It is bounded N. by Kentucky and Virginia, S. E. by North Carolina, S. by Georgia, Alabama, and Mississippi, and W. by Arkansas and Missouri, from which it is separated by the Mississippi river. The state is divided into 84 counties, viz.: Anderson, Bedford, Benton, Bledsoe, Blount, Bradley, Oampbell, Cannon, Carroll, Carter, Cheatham, Claiborne, Cocke, Coffee, Cumberland, Davidson, Decatur, De Kalb, Dickson, Dyer, Fayette, Fentress, Franklin, Gibson, Giles, Granger, Greene, Grundy, Hamilton, Hancock, Hardin, Hawkins, Hardeman, Haywood, Henderson, Henry, Hickman, Humphreys, Jackson, Jefferson, Johnson, Knox, Lauderdale, Lawrence, Lewis, Lincoln, McMinn, McNairy, Macon, Madison, Marion, Marshall, Maury, Meigs, Monroe, Montgomery, Morgan, Obion, Overton, Perry, Polk, Putnam, Rhea, Roane, Robertson, Rutherford, Scott, Sequatchie, Sevier, Shelby, Smith, Stewart, Sullivan, Sumner, Tipton, Union, Van Buren, Warren, Washington, Wayne, Weakley, White, Williamson, and Wilson. The chief cities and towns are: Nashville, the seat of government; Memphis, the most important commercial point; Knoxville, Columbia, Murfreesborough, Shelbyville, Lebanon, Pulaski, Jackson, Brownsville, Franklin, Greenville, and Dresden. The following table exhibits the decennial progress of population since 1790:

Census.	White.	Free colored.	Slaves.	Total.	Increase per cent.
1790....	32,018	861	8,417	35,791	...
1800....	91,709	809	13,584	105,602	195.05
1810....	215,875	1,817	44,585	261,737	147.84
1820....	389,927	2,719	90,107	482,813	61.65
1830....	535,746	4,555	141,808	681,904	61.25
1840....	640,627	5,524	188,059	829,210	21.60
1850....	754,586	6,432	289,459	1,047,717	30.92
1860....	824,223	7,235	275,784	1,107,947	10.63

Density of population in 1850, 21.98 to the square mile; in 1860, 24.12; ratio to the total population of the Union in 1860, 3.85 per cent. Of the white population in 1850, 382,235 were males and 374,601 females; of the free colored, 3,117 males and 3,305 females; and of the slaves, 118,780 males and 120,679 females. Of the free colored, 2,646 were blacks and 3,776 mulattoes; of the slaves, 219,103 blacks and 20,856 mulattoes. The white and free colored inhabited 129,419 dwellings, and constituted 180,604 families. Births (white and free colored) in 1849-'50, 23,090 (3.03 per cent.); deaths, 7,825 (1.03 per cent.), and including slaves, 11,874 (1.18 per cent.); married (whites), 7,872 (1.04 per cent.). Deaf and dumb, 377; blind, 474; insane, 407; idiotic, 848. Of the white and free colored population (763,258), there

were born in the state 585,385; in other states, 170,184; in foreign countries, 5,653; unknown, 1,586. Ages of the total population: under 1 year, 30,151; 1 and under 5 years, 140,117; 5 and under 10, 187,608; 10 and under 15, 142,257; 15 and under 20, 118,260; 20 and under 30, 172,851; 30 and under 40, 101,250; 40 and under 50, 65,579; 50 and under 60, 40,486; 60 and under 70, 21,255; 70 and under 80, 9,483; 80 and under 90, 2,976; 90 and under 100, 573; 100 and upward, 148; unknown, 224. The occupations of 168,240 free male persons over 15 years of age were as follows: commerce, trade, manufactures, mechanic arts, and mining, 23,432; agriculture, 118,979; labor not agricultural, 17,559; navigation, 258; law, medicine, and divinity, 3,363; other pursuits requiring education, 3,589; government civil service, 705; domestic servants, 10; other pursuits, 345. The number employed in manufacturing establishments in 1820 was 7,860; in 1840, 17,815; in 1850, 12,082. The number of slaveholders in 1850 was 38,864, viz.: holders of 1 slave, 7,616; of 1 and under 5 slaves, 10,583; of 5 and under 10, 8,814; of 10 and under 20, 4,852; of 20 and under 50, 2,202; of 50 and under 100, 276; of 100 and under 200, 19; of 200 and under 300, 2; of 300 and under 500, 1. The federal representative population of Tennessee in 1850 was 906,933, and entitled the state to 10 members of congress; in 1860 it was 1,031,794, giving, under the new apportionment, 8 members.—The Mississippi river, washing the western border of the state, gives it important commercial advantages which have been successfully improved. The Cumberland river, rising in Kentucky, traverses N. Tennessee for a distance of 250 m., and returning to Kentucky falls into the Ohio at Smithland; it is navigable by the largest steamboats to Nashville, and by smaller boats to Waitsburg, Ky., 400 m. above. The Tennessee traverses the state in a S. W. direction, passes across the N. part of Alabama, and returning runs due N. across Tennessee and Kentucky into the Ohio at Paducah. The other principal streams are the Holston and its affluents, the Watuga, Nolichucky, French Broad, and Little river; the Hiwassee, Sequatchie, Duck, and Elk, all tributaries of the Tennessee; the Oahey fork of the Cumberland; and the Obion, Hatchie, and Wolf, which flow into the Mississippi. Nearly all of these are navigable by steamboats or small vessels. The facilities for water communication are unsurpassed, and there is a great abundance of water power for manufacturing purposes.—The range of mountains which forms the boundary between North Carolina and Tennessee bears in its different divisions the local names of Stone, Iron, Bald, Smoky, and Unaka mountains. South-west of this ridge is the valley enclosed by it and the Blue ridge, in which are the head streams of the Tennessee, and further W. are the Cumberland mountains, which stretch across the state from N. to S., bearing a little S. W., and in the middle of the state take a W.

direction, gradually diminishing into moderately hilly ridges, enclosing beautiful and fertile valleys. These mountains in some places occupy a breadth of 50 m., and are a prolongation of the Alleghany range and the Laurel and Chestnut ridges. All the mountains of Tennessee belong to the great Appalachian chain, and the loftiest are not more than 2,000 feet above the level of the sea. The surface of the state consists of three natural divisions: East Tennessee, comprising the mountainous region from the E. boundary to the Cumberland mountains; Middle Tennessee, embracing the hilly portion of the state from the Cumberland mountains to the Tennessee river; and West Tennessee, composed of the level part lying between the Tennessee and Mississippi rivers. —Tennessee is divided geologically into 5 districts or cross belts running from N. to S. The first, comprising the interval between the Mississippi and Tennessee rivers, is occupied (in an order from W. to E.) by the alluvial, the tertiary, and the cretaceous formations of the gulf of Mexico and the Atlantic seaboard. The 2d or central portion of the state, from the Tennessee river to the W. foot of the Cumberland mountains, is a rolling country of nearly horizontal palaeozoic rocks, with a great island-like district of lower silurian ground in the centre, watered by the Cumberland, Stone's, Duck, and Elk rivers, and surrounded on all sides by devonian hills. The 3d is the mountain division of the coal; a plateau 8,000 feet above the sea, 40 m. wide by 140 long, bounded on the E. by the valleys of the upper Tennessee and Holston rivers, and covered with a plate of carboniferous rocks, which is thinned and broken up into patches and mounds as it approaches the Alabama state line. The last workable coal mines of any importance going S. are the Sewanee mines at the N. end of a branch railroad 16 m. long, which leaves the Nashville and Chattanooga railroad at the tunnel where it crosses the mountain. The Sequatchee river valley, cut down through this plateau to its base, follows the line of a profound fault like those which characterize the belt next to be described. The 4th district is the great valley of Knoxville or East Tennessee, through which the waters of S. W. Virginia flow to compose the upper Tennessee river. It is a prolongation of the great valley of Virginia, the valley of the Shenandoah, and the valley of Harrisburg and Reading, Penn. Its rocks are of silurian age, upturned and broken by enormous faults, which bring them against the coal. On the E. side of this great valley rise the Onaka or Smoky mountains, forming a 5th district, the true prolongation of the Blue ridge and South mountain range, extending laterally into North Carolina, and composed of rocks of undetermined age, the equivalents of the slate rock, gneiss, and marble of western Massachusetts and Vermont, and probably of "calciferous sandrock" age. Among these rocks (as at Alton in Canada) occur the remarkable copper

mines of Ducktown, Polk co. (See COPPER MINES.) The limestone of the great valley yields, at innumerable places, fine limonite or brown hematite iron ore, affording stock for many forges and furnaces, which receive an additional supply from long straight outcrops of "dyestone" or upper silurian fossil ore along the whole W. side of the great valley. Lead and zinc ores are also met with, but have been little worked. This district also affords brecciated marbles, large quantities of which have been introduced in the new capitol at Washington. (See MARBLE.) The remarkable iron-making region, with its numerous furnaces, in the W. part of the state, between the Tennessee and Cumberland rivers, is a prolongation and widening out southward of the iron region of western Kentucky. Its ores are subcarboniferous brown hematite deposits in hills of sand and gravel. (See IRON.) —Like other regions where the cavernous limestone is the prevailing surface rock, Tennessee has numerous caves, of which but few have yet been explored. In the Cumberland mountains are several which are 100 feet or more below the surface and several miles in extent. One has been descended to a depth of 400 feet, where a stream of water was found having sufficient force and fall to drive the machinery of a mill. Another, on the summit of Cumberland mountain, is perpendicular in its descent, and its depth has never yet been fathomed. Some of these caves contain fossils and bones of extinct species of animals. Big Bone cave when first explored contained a skeleton of the mastodon. The Enchanted mountain, also one of the Cumberland range, has impressions of the feet of men and animals in the limestone rock. There are throughout the cavernous limestone region occasional "sink holes," as they are termed, where the roof of a cavern has given way under the superincumbent pressure, and a tract of several acres, often with a grove of trees and sometimes with dwellings upon it, has sunk down 75 or 100 feet below its former level. Near Manchester, Coffee co., is an ancient work called the Stone Fort, enclosed by a rude stone embankment by tourists called a wall, upon which trees are growing whose age is estimated at over 500 years. This mysterious enclosure lies in a peninsula formed by the near approach of two forks of Duck river, and occupies an area of 47 acres. —The climate is generally mild and remarkably salubrious, excepting in the swampy districts of the N. W. The eastern division is noted for its pure, bracing mountain air. East Tennessee, from its rough and mountainous character, has but a limited surface adapted to cultivation. The soil of Middle Tennessee is generally good, producing large crops of wheat, rye, oats, Indian corn, buckwheat, barley, potatoes, hemp, hay, sweet potatoes, flax, cotton, and tobacco. The western division is almost level, and cotton, tobacco, and all kinds of grain are grown in extraordinary abundance.

The soil of this part is a rich black mould of unsurpassed fertility. Along the banks of the Mississippi and Tennessee are extensive cane brakes, covered with reeds of immense size. The state altogether forms one of the finest agricultural regions on the continent. The country is well watered, and has an abundance of choice timber. The N. W. part contains an extensive tract of swampy land. The high mountains in the east are covered with forests of pine, which yield tar, pitch, turpentine, and lumber for exportation. On the mountain slopes the sugar maple, cedar, juniper, and savin are also abundant; and in the lower lands as well as in Middle Tennessee the poplar, hickory, black walnut, oak, beech, locust, and cherry are found. In the swamps and lowlands of West Tennessee the cypress, hickory, cottonwood, and swamp cedar occur in large quantities. The pawpaw, a low bushy tree or shrub, bearing a fruit somewhat resembling the banana, though inferior to it, is found in the river bottoms. The wild animals of the state are the bear, found only in the mountainous districts, deer, raccoons, foxes, opossums, and squirrels. Horses, cattle, sheep, and swine are raised on a large scale, and many thousands are annually exported. The hills and mountain slopes afford an abundance of fine pasturage. Much attention is given to wool growing, and there are hundreds of flocks of sheep of the best varieties. A state agricultural bureau was established in 1854, and an annual bounty is paid to district and county societies under certain regulations. In 1859 there were 37 county societies organized in the state, and the general interest taken in these associations is proving highly beneficial to the farmers.—The number of farms and plantations in Tennessee in 1850 was 72,735, embracing 5,175,178 acres of improved and 13,808,849 of unimproved land, valued at \$97,851,212; an average of 261 acres to each farm, and of \$5.10 per acre. The value of implements and machinery was \$5,860,210. The live stock consisted of 270,636 horses, 75,308 asses and mules, 250,456 milch cows, 86,255 working oxen, 414,051 other cattle, 811,591 sheep, and 3,104,800 swine, all valued at \$29,978,016. The numbers of asses and mules and of swine were the largest of any state in the Union. The value of animals slaughtered in the census year was \$6,401,765. The products of animals were: wool, 1,864,378 lbs.; butter, 8,139,585 lbs.; cheese, 177,681 lbs. The value of live stock, June 1, 1860, was \$61,200,000. The crops of 1859, as returned by the census of 1860, were as follows: wheat, 5,410,000 bushels; Indian corn, 50,748,000; oats, 2,343,000; Irish potatoes, 1,175,000; sweet potatoes, 2,614,000; flax, 146,000 lbs.; tobacco, 38,981,000; cotton, 212,000 bales; hay, 146,000 tons; wool, 1,400,000 lbs. During the year ending June 1, 1860, the values of some of the chief manufactures were as follows: sawed and planed lumber, \$1,970,000; flour, \$3,820,-

000; steam engines and machinery, \$170,000; agricultural implements, \$18,000; bar iron, \$483,000; pig iron, \$457,000; home manufactures, \$3,166,000. Total value of products of industry, \$17,080,000.—Tennessee, being an interior state, has but little foreign commerce, though Memphis and Nashville are ports of entry; but its commerce with New Orleans, St. Louis, Louisville, and Cincinnati, through its navigable rivers, is very large; and by means of its railroads it is in connection with Mobile, Charleston, and Savannah. The exports are principally live stock, pork, bacon, lard, butter, ginseng, cotton bagging, flour, Indian corn, fruits, tobacco, cotton, hemp, feathers, and a little saltpetre. Tennessee has 23 lines of railroad; all, except some small branch railroads, proceeding from 3 centres, Memphis, Nashville, and Knoxville. Memphis and Nashville are thus connected with Cairo and St. Louis, with New Orleans and Mobile, with Charleston and Savannah, with Bowling Green and Louisville, with Nashville, and with Knoxville, Lynchburg, Richmond, and Washington. Knoxville is connected with Memphis, with Atlanta and Charleston, with Columbia, S. C., and Wilmington, N. C., on the S.; with Danville, Lexington, and Cincinnati on the N.; and with Lynchburg and Richmond on the E. On Jan. 1, 1861, there were 1,412.68 miles of railroad projected in the state, of which 1,238.54 were in operation; the cost of the lines already completed was \$30,793,180. On Jan. 1, 1860, there were 34 banks in the state, the condition of which was as follows: capital, \$3,067,037; loans and discounts, \$11,751,019; stocks, \$1,233,432; real estate, \$595,759; other investments, \$84,355; due by other banks, \$2,618,910; notes of other banks, \$495,362; specie funds, \$93,092; specie, \$2,267,710; circulation, \$5,538,378; deposits, \$4,824,799; due to other banks, \$264,627; other liabilities, \$462,420.—There is a state hospital for the insane near Nashville, which has accommodations for 250 patients, and has 455 acres of land connected with it; number in the hospital in 1860, 211; the expenditure is about \$48,000 per annum. There is also an institution for the instruction of the blind in Nashville, which in 1860 had 36 pupils, and the expenditures were \$7,642; the state allows \$200 a year for each indigent blind pupil. At Knoxville there is a school for the deaf and dumb, which is also allowed \$200 per annum for each indigent pupil; the number of pupils in 1860 was 61, and the expenditures \$13,000. The Tennessee penitentiary is at Nashville; it is conducted upon the Auburn or silent system, and on Sept. 30, 1859, had 373 inmates, of whom 366 were white males and 3 white females, 8 black males and 1 black female; 156 were natives of Tennessee, and 60 were born out of the United States; 10 were sentenced for life, and 73 for 10 years and upward.—The following table gives the principal colleges and professional schools with their statistics to about Jan. 1860:

Institutions.	When founded.	Instructors.	Students.	No. of vols. in libraries.	Remarks.
University of Nashville, Nashville.....	1806	8	104	10,000	
Franklin college, near Nashville.....	1844	6	106	4,000	
East Tennessee university, Knoxville.....	1806	8,500	
Cumberland university, Lebanon.....	1844	11	165	4,000	Cumberland Presbyterian.
Jackson college, Columbia.....	1828	5	84	4,500	
Union college, Murfreesborough.....	1848	6	150	4,600	Baptist.
Greenville college, Greenville.....	1796	2	20	3,600	
Washington college, Washington co.....	1795	3	..	2,000	
South-western university.....	1860	Not yet in operation.
South-western theological seminary, Maryville.....	1821	2	24	6,000	Presbyterian.
Theological school of Cumberland university.....	1855	2	58	..	Cumberland Presbyterian.
Cumberland university law school.....	1847	3	188	500	
Medical department of Nashville university.....	1850	8	486	..	
Medical department of East Tennessee university.....	1856	5	

There is a common school fund, declared by the constitution to be perpetual and not to be diminished, which consists of \$1,500,000 deposited in the bank of Tennessee; of property given by deed, will, or otherwise for the use of the common schools; proceeds of escheated lands and lands donated by the United States; and the personal effects of intestates having no kindred entitled thereto by the laws of distribution. The annual fund for distribution to the schools in 1859 was \$230,430.27. It consisted of the dividends from the bank of Tennessee, bonuses of banks and other incorporated companies, 25 cents on each \$100 of capital of banks organized under the banking law of the state, and sundry taxes. The distribution is made at the rate of 75 cents per scholar. The scholastic population in 1859 was 294,497. The number of free persons over 20 years of age in the state who could not read or write in 1850 was 78,619. There were in the same year 264 academies in the state, with 404 teachers and 9,928 pupils, and an annual income of \$155,902. The college and seminary libraries of the state in 1860 had 46,000 volumes, the state library 9,000 volumes, and other public libraries at least 15,000 volumes more, making a total of 70,000 volumes. —The leading religious denominations in Tennessee are Methodists, Baptists, and Presbyterians. Of the last named there are several distinct organizations, the most prominent of which are the Cumberland and the Old School Presbyterians. In 1850 there were 867 Methodist churches in the state, holding church property to the amount of \$381,811; 648 Baptist churches, \$271,899; and 363 Presbyterian churches, \$367,081. The church accommodations for these 3 denominations the same year were: Methodists, 247,853 sittings; Baptists, 197,315; Presbyterians, 185,517. The other denominations were: Disciples or Campbellites, 63 churches; Episcopalians, 17; Free churches, 80; Friends, 4; Lutherans, 12; Roman Catholics, 4; Union churches, 15; Dunkers, 1, &c. The whole number of churches was 2,027, and of sittings 628,495, and the total value of church property \$1,316,201. In 1850 there were 8 daily, 2 triweekly, 36 weekly, and 4 monthly newspapers published in Tennessee, being an aggregate of 50, and printing annually 6,940,750 copies.—The governor of Tennessee is elected by popular vote for 2 years, and has a salary of \$3,000 per annum. The legislature

consists of a senate of 25 members and a house of representatives of 75, both elected by the people. The legislature meets biennially on the first Monday of October in the odd years. The secretary of state, treasurer, comptroller, and attorney-general are chosen by the legislature on joint ballot, the first named for 4 years, the others for 2 years. The secretary of state receives \$800 and fees; treasurer, \$1,500 and fees; comptroller, \$2,750 and fees; attorney-general, \$1,500 and fees. The judiciary consists of a supreme court of 3 judges, having appellate jurisdiction only, elected by the people for 8 years, and receiving a salary of \$2,500 each; 15 circuit judges, and 6 chancellors of the court of chancery, also elected by the people for 8 years, and each having a salary of \$2,000. There are 3 special courts, the criminal court of Davidson co. (in which Nashville is situated), the criminal court of the city of Memphis, and the common law and chancery court of the same city; the judges of these receive respectively \$1,500, \$2,000, and \$1,800 salary. The present constitution, adopted in 1835, provides that every free white male of the age of 21 years, being a citizen of the United States, and a resident of the county wherein he may offer his vote 6 months next preceding the day of election, may vote for members of the general assembly and other civil officers. Representatives must be at least 21 years of age, and senators 30. No clergyman or person holding office under the U. S. government is eligible to a seat in the legislature; and no person who denies the being of a God or a future state of rewards and punishments can hold any office in the civil department of the state. All persons concerned in duels, either as principals, seconds, aiders, or abettors, are deprived of the right to hold any office of honor or profit. No person who is or has been a collector or holder of public moneys can have a seat in either house of the general assembly until he shall have accounted for and paid into the treasury all sums for which he may be accountable or liable. A plurality of lucrative offices is forbidden. No judge can preside on the trial of any cause in the event of which he may be interested, or where either of the parties is connected with him within the degrees of consanguinity, or in which he may have been counsel, or in which he may have presided in an inferior court, except by consent of all the parties.

The bill of rights is made a part of the constitution, and is not repealable by the legislature, but shall for ever remain inviolate.—In Sept. 1851, the value of the real and personal property of the state was \$260,319,611, of which \$166,417,907 was real estate, \$82,319,728 slaves, other taxables \$11,581,982. In Sept. 1859, the aggregate taxable property of the state had increased to \$877,208,641; and in 1860 it was \$493,903,892. The average value of land per acre in 1859 was \$8.19; of slaves, \$854.65. The receipts of the state treasury for the two years ending Oct. 1, 1859, were \$1,848,094.88, of which was received from taxes on property and polls, \$878,087.50; taxes on registration of deeds and lawsuits, \$375,509.09; bank of Tennessee dividends, \$420,408.32; dividends of turnpike roads, \$84,093.04; bank and insurance company bonuses, \$29,417.96; railroad sinking fund, \$88,358.45. The whole expenditure was \$1,704,287.61, of which \$20,521.57 belonged to executive, \$118,574.05 to legislative, and \$226,180.59 to judicial expenses; \$457,257.93 was paid as interest, \$471,950.80 for educational purposes, \$40,512.88 for the deaf and dumb and blind, \$66,500 for the insane hospital, \$43,683.71 for the penitentiary, \$25,841.87 for agricultural purposes, \$83,092.60 was invested in the sinking fund, and \$29,660.64 expended in the codification and publication of the laws of the state. The absolute liabilities of the state, Oct. 1, 1859, were \$3,844,606.66, on which \$209,388.25 of interest annually accrues. Of this, \$2,063,606.66 were internal improvement bonds, \$1,125,000 bank bonds, \$608,000 bonds for the erection of the state capitol, and \$48,000 bonds for the purchase of the Hermitage, Gen. Jackson's former residence. In addition to these absolute liabilities, the state has contingent liabilities to the amount of \$12,799,000 for indorsing bonds of or lending its own bonds to certain railroads and plank or macadamized roads; for the extinction of these a sinking fund has been commenced, which, in Oct. 1859, amounted to \$109,750. The aggregate absolute and contingent debt of the state on Oct. 1, 1859, was \$16,643,666.66. In 1857 the state owned stocks, mostly productive, costing \$3,292,717, and which were estimated as worth \$2,244,827.—The name of Tennessee is derived from Tannasee, the Indian name applied to the Little Tennessee river. De Soto probably visited the spot where Memphis now stands as early as 1549. The first settlement was attempted in 1754 by a small body of North Carolinians, but they were speedily driven from the country by the Indians. In 1756 the first permanent settlement was made, and Fort Loudon built on the Tennessee river about 80 m. from the present site of Knoxville. This was the first Anglo-American settlement W. of the Alleghanies and S. of Pennsylvania. For a time the settlers had peaceable intercourse with the Indians, but in a few years the Cherokees were incited by the French to commit depredations, and in 1760 had become so troublesome that

an expedition was sent to the relief of the settlements; but after repeated conflicts with the savages the troops retreated, and the Indians seizing the opportunity besieged the garrison at Fort Loudon. Unable to resist their greatly superior force, the whites capitulated, stipulating that they should be allowed to return to North Carolina without molestation. On the second day of their march they were overtaken by the treacherous savages and many of them butchered, and the survivors reduced to captivity. In 1761 another armed force from Virginia and North Carolina entered the district, and after frequent successful battles with the Indians compelled them to sue for peace. A treaty was made, which was observed honorably by the Indians for some time, and the settlements along the Watauga and Holston rivers increased rapidly, being known from 1769 to 1777 as the Watauga association. In 1774 the Tennesseans assisted their Virginia neighbors in Lord Dunmore's war, and behaved gallantly at the battle of Point Pleasant on the Kanawha, at which the Indians were finally routed. In the colonial assembly of North Carolina in 1776 the territory was represented by deputies as the district of Washington; and in the revolutionary war the settlers flocked to the standard of the colonists, and fought with great bravery at King's mountain, Guilford Court House, and other places in the South. At the close of the revolution a settlement was made on the Cumberland river where Nashville now stands. From 1777 to 1784 the territory formed part of North Carolina, which set apart a portion of the district in the vicinity of Nashville for bounty lands for her revolutionary soldiers. In 1785 the people became dissatisfied with the manner in which they were treated by the government of that state, and organized the state of Franklin, which was maintained until 1788, when it was again united with North Carolina. In 1789 North Carolina ceded the territory to the general government, and in 1790 it was organized, together with Kentucky, as the territory of the United States south of Ohio. In 1794 a distinct territorial government was granted to Tennessee; and in 1796 a state constitution was formed at Knoxville, and Tennessee was admitted into the Union. In the war of 1812 her troops distinguished themselves by their daring and intrepidity; and Andrew Jackson, a citizen of the state, was one of the most distinguished generals of the war. James K. Polk, the 11th president of the United States, was also a citizen of the state. In 1860 Tennessee was the fourth in population and importance among the slave states. On Jan. 17, 1861, the Tennessee legislature, which had been elected in Aug. 1859, resolved to submit to a vote of the people the question of calling a state convention for the passage of a secession ordinance, and the election of members of such convention, to serve if a majority directed its assembling. The vote

was taken on Feb. 9, and resulted in a majority of 11,935 against a convention, out of a total vote of 127,591; the union candidates for the convention received a vote of 88,868, against 24,749 for disunion candidates, and no one of the latter was elected. On May 6 the legislature, then in extra session at the call of the governor, passed an act to submit to a vote of the people, on June 8 following, "a declaration of independence and ordinance dissolving the federal relations between the state of Tennessee and the United States of America." On the same day they authorized the governor to raise a provisional force of volunteers for the defence of the state, and, should it become necessary for the safety of the state, to call out the whole available military strength; and for the purpose of carrying out this provision, he was authorized to issue and dispose of \$5,000,000 of bonds bearing 8 per cent. interest, and payable in 10 years. On May 7 commissioners appointed by Gov. Harris met the accredited representative of the confederate states at Nashville, and formed a league which the legislature ratified the same day, and by which Tennessee agreed to place her troops under the control of the president of the confederate states, in the same way as if the state had already seceded, and to turn over to the confederacy, as soon as she did secede, all United States property; and the confederate government agreed to refund her expenditures when she seceded. Twenty-five thousand men were raised immediately, and stationed at Nashville and other important points in the state. The number of votes polled at the election on June 8, on the question of separation or no separation, according to the returns, was 152,143, and the majority for separation was stated to be 57,667. During the ensuing 10 months the state raised over 50 regiments for the confederate government, beside 5 or 6 raised by the unionists for the U. S. government. After the capture of Forts Henry and Donelson on the Tennessee and Cumberland rivers, in Feb. 1862, Nashville was evacuated by the confederate forces and occupied by the U. S. army early in March. Andrew Johnson was immediately appointed by President Lincoln military governor of Tennessee, and a strong feeling of loyalty to the Union, which had all along prevailed in the eastern part of the state, began to manifest itself in the western part also. On April 14 the city council of Nashville passed a resolution requesting the mayor of the city to have the flag of the United States placed upon all public property belonging to the corporation; and on May 8 a body of some 150 influential citizens issued a call for a public meeting, as a measure preparatory for the restoration of the constitutional relations of Tennessee with the federal government.

TENNESSEE RIVER, the largest tributary of the Ohio, formed by the union of the Clinch and Holston rivers, which rise in S. W. Virginia, and, after each receiving several affluents,

unite near Kingston, Roane co., Tenn. At first the course of the Tennessee is due S. W. to Chattanooga, near the S. line of the state, where it passes through a part of the Cumberland range of mountains in a series of bends, and near the village of Jasper, Marion co., again turns S. W., entering the state of Alabama, and at Gunter's Landing, Marshall co., Ala., assumes a direction nearly W. by N. Between Lauderdale and Lawrence counties it spreads in a broad but shallow expansion called Muscle shoals, flowing over flint and limestone rocks in a succession of rapids for 20 miles, and affording a large amount of water power. At Chickasaw on the Mississippi line the river turns N. W., and forms the boundary thence to the Tennessee line between Alabama and Mississippi. Reëntering Tennessee, after a circuit of nearly 300 m. in Alabama, it flows almost due N. till it reaches Birmingham, Ky., when it turns W. N. W. and enters the Ohio at Paducah, McCracken co., 49½ m. from its mouth, near lat. 37° N. and long. 88° 35' W. Its length from Kingston to Paducah is estimated at 800 m., but from the source of its longest affluent, the Holston, it is more than 1,100 m. in length. Its principal tributaries are the Sequatchie, Paint Rock, Flint, and Duck rivers, and Elk and Shoal creeks, entering it from the N.; and the Hiwassee, Big Sandy, and Clark's rivers, and Town and Big Bear creeks, from the S. The fall of the river in its whole course is computed at about 2,000 feet. There are no rapids obstructing navigation except those at the Muscle shoals, below which it is navigable to its entrance into the Ohio, 259 m.; and above the shoals steamboats ascend as far as Knoxville, nearly 500 m., though at low water the navigation through the "whirl" in Marion co., Tenn., is difficult. The river has few large towns on its banks, being for much of the distance occupied by plantations; the only important ones are Chattanooga, Tenn., Tusculumbia and Florence, Ala., and Paducah, Ky. The scenery on the upper portion of the river is very beautiful. Darby estimates the area drained by the Tennessee and its tributaries at 41,000 sq. m. The river is seldom frozen, the ice having closed it completely but twice in more than 80 years.

TENNIS, a game of ball, played in a court by 2 persons, or by 4 divided as partners. Tennis courts are usually 96 feet long by 83 wide, with a wall sufficiently high to prevent the loss of balls by ordinary strokes. The ball is struck with a bat, called a racket, whose striking part is covered with a close hard network of animal tendon. The player or party in strikes a ball, or "serves" it, against the head wall of the court. This ball must come to the ground over a line drawn at a given distance from the head wall. It is returned by the player or party out, who must in turn deliver it, by its rebound, at a certain place in the court, when it is again struck by the player in; and so the game continues. Whoever fails

to "put the ball up" properly on the head wall, or to deliver it at the proper place on the court, loses. If it is the player in that fails, he loses his hand, and goes out; if it is the player already out, his adversary scores a stroke toward game.—The same game played without a bat, when the ball is struck with the palm of the hand, is called *fives*, hand tennis, or more commonly hand ball. Hand ball, as still played in Great Britain and the United States, appears to have been the original game; but in France it became the custom to play hand ball with a heavy glove on, then with cords or tendons bound round the hand, or with a piece of wood bound to the hand and wrist, whence it was an obvious step to the racket. From this name of the bat, the game is sometimes popularly called racket.

TENNYSON, ALFRED, an English poet, born at Somersby, Lincolnshire, in 1810. He was the third of the 11 or 12 children of Dr. George Clayton Tennyson, a Lincolnshire clergyman, remarkable for energy and physical stature. His uncle Charles Tennyson, known as the Right Hon. Charles Tennyson d'Eyncourt, was authorized by royal license in 1835 to superadd the name of d'Eyncourt to commemorate his descent from that ancient Norman family, and sat in 10 successive parliaments, representing for 20 years the metropolitan borough of Lambeth. It is related that writing tales and verses was a favorite amusement of all the children in the parsonage of Somersby. The 8 eldest sons were educated at Trinity college, Cambridge, and were pupils of Dr. Whewell, then one of the tutors. In 1828 Frederic obtained the prize for a Greek poem; in 1829 Alfred received the chancellor's medal for an English poem, of 250 lines, in blank verse, entitled "Timbuctoo;" and at nearly the same time Alfred and Charles published privately a volume of "Poems by Two Brothers." Charles entered the church, in 1835 became vicar of Graysby, and on inheriting a property in Lincolnshire through his paternal grandmother assumed her family name of Turner. Frederic published in 1854 a collection of poems entitled "Days and Hours." The first volume bearing the name of Alfred Tennyson was "Poems, chiefly Lyrical" (London, 1830), which appeared while he was still an undergraduate. It consisted of about 150 pages, and among its pieces were "Claribel," "Lilian," "Isabel," "Mariana," "Madeline," "The Merman," "The Mermaid," "The Sea Fairies," "The Kraken," "The Dying Swan," and "The Ballad of Oriana." It made little impression, and met with slight favor from the critics, though Professor Wilson declared the author to have genius as well as affectations, and predicted his fame as a poet. In this first series he seems to have cautiously avoided subjects of reality and human interest, to have wilfully abstained from any attempt to delineate actual life, passion, or thought, and to have selected remote and fanciful themes or partial and fugitive

phases of life, as if for the exclusive purpose of exercising his art, of attaining mastery over the resources of metre, rhythm, and phrasing, and of elaborating a musical style capable of nobly and naturally expressing the ideas which a ripening intellect and enlarged experience should supply. But, though aiming chiefly at artistic expression, and dwelling upon scenery that is strange and emotions that are scarcely human, the volume exhibits his power of producing pictures in which the landscape and the figures seem alike colored by a dominant idea, in which every descriptive detail and epithet contributes to the dramatic unity of the subject and the intensity of the general impression. His imagination concentrates its resources upon a limited and peculiar view, so that each of his female heroines stands for a detail; Claribel is a shadow, Lilian a peal of laughter, Mariana a melancholy look, and Isabel an attitude. His exquisite rhythm and diction, though sometimes reproached for mannerism and conceits, were best illustrated in "Oriana," "Recollections of the Arabian Nights," and "Mariana in the Moated Grange," which, if expression were the highest aim of poetry, would be among the most perfect of poems. His second volume, published by Moxon (London, 1833), contains several poems from the first, carefully retouched and improved. Among its new pieces were "The Miller's Daughter," "Enone," "The Palace of Art," "The May Queen," "The Lotos Eaters," "A Dream of Fair Women," "The Lady of Shalott," and "Mariana in the South." In most of these the painter, rather than the poet, continues to predominate, and the pictures are still remarkable rather for a remote beauty than for presenting realities of thought and affection. But "The Miller's Daughter" and "The May Queen" touched upon the interests of every-day life, revealed his power to command popular sympathy, and extended the as yet small circle of his admirers. Their charm consists in the skill with which tragic completeness and intensity are exhibited in lives moved by the simplest affections and enjoyments. "The Lotos Eaters" better illustrates the prevailing character of the volume, being merely picture and music, a rhythmical expression of the feelings of imaginary beings in an imaginary realm. Though "The Palace of Art" was avowedly an allegory, yet the pictorial and musical element prevails over the ethical and philosophical aim, and, instead of dramatizing the process by which the soul becomes discontented with a mere artistic and isolated enjoyment of the universe, the whole force of treatment is expended upon the magnificent description of the palace, while the moral is stated but not developed. His second collection, like his first, was in the main severely noticed by the critics, and for 9 years he remained silent. His third series (3 vols., 1842) contained, beside some of his former pieces considerably changed, new and various

poems which are still among the most admirable illustrations of his power. Among the latter were "Morte d'Arthur," "Godiva," "St. Simeon Stylites," "Ulysses," "St. Agnes," and "Sir Galahad," founded on legendary history; the poems of love, "The Gardener's Daughter," "Dora," "Love and Duty," "Lady Clara Vere de Vere," "The Talking Oak," "The Lord of Burleigh," and "Locksley Hall," and lyric allegories illustrating great moral problems or laws, as "The Two Voices" and "The Vision of Sin." The "Morte d'Arthur" is essentially the answer of a Christian poet to lamentations of the Christian ritualist and dogmatist over the decay of faith; "Ulysses," admirable in all respects, is a faultless specimen of blank verse; "The Gardener's Daughter" presents a combination of excellences perhaps unrivalled in any other love story, and never deviates from the simplicity of familiar life; and the hero of "Locksley Hall," one of his most finished and brilliant works, rises from an early disappointment in love to find resources in enterprise and action and in glowing anticipations of progress for the human race. No other poem more completely than the last shows his mastery of rhythm and language, or his sympathy with the tendencies and triumphs of the present age. From the publication of these volumes his preëminence among contemporary English poets began to be acknowledged. His next work, "The Princess, a Medley," appeared in 1847. Very diverse judgments were expressed concerning it. A prince and a princess are affianced without having seen each other; the lady repudiates the alliance, but relents after a series of adventures as improbable as the romances of chivalry; and the whole poem is "earnest wed with sport," treating the relation of man and woman with mock-heroic fancy, yet touching history and metaphysics with scientific precision as well as poetical grace, mingling the pleasantry of a picnic party with hopeful interpretations of socialistic theories, and rising seriously at the close to a conception of

The two-beated heart beating with one full stroke
 LII.

Some of his finest lyrical passages, as the bugle song, are interspersed. In 1850 appeared, at first anonymously, the poems of "In Memoriam," designed to express the feelings caused by the loss of his most intimate friend, the gifted Arthur Henry Hallam, who was betrothed to his sister. They are the "wild and wandering cries" of grief versified, the brief stanzas bodying forth the fancies, passing moods, yearnings, regrets, questionings, and consolations suggested at such a time. The volume contains 129 short poems, each consisting of several elegiac quatrains and presenting one leading idea, and its wisdom and beauty were ripened during an interval of nearly 20 years. In many passages he makes science subservient to poetry, illustrates the conflict between a distrustful intellect and a passionate intuition, and amid dear-

est hopes and darkest doubts "stretches lame hands of faith and gropes." Philosophical rather than pathetic, sometimes obscure, and traversing a wider circuit of thought than his other poems, the volume is perhaps less popular though often more highly admired than either of his others. He was appointed to the office of poet laureate after the death of Wordsworth, and his next publication was "Maud, and Other Poems," in 1855. The misanthropic hero who tells the story of "Maud" rushes madly from wrecked affections, scorning the social conventions by which he is thwarted, to find comfort and hope in the war which then occupied the British nation. A few critics understood and applauded the poem as significant of the awakening of his countrymen from commercial epicureanism, in which meanness, cheating, crime, and misery were rife, to a generous enthusiasm and martial purpose. Among the minor pieces in the volume was the "Ode on the Death of the Duke of Wellington," the finest work of art which any poet laureate has ever produced in discharge of the functions of his office. In 1859 appeared the "Idyls of the King," four poems, from 700 to 2,000 lines in length, upon a subject long meditated by the author, the legends of King Arthur. In form they hold a position between the idyl, as usually understood, and the epic; in tone, they are purely epic. The materials seem to be drawn from the original French and Welsh sources, rather than from the old English compilation of Mallory; the style is marked by an unaffected simplicity and grandeur suited to the spirit of the Arthurian chivalry; each of the stories is complete in itself; and the last, entitled "Guinevere," has been called his highest effort. The volume touches upon but few of the adventures in the cycle of Arthurian romance, and is believed to be only the commencement of a series of similar poems.—The mind of Tennyson seems in exact harmony with the times in which he lives. In ideas and in phraseology he echoes back the dominant feelings of his age, is touched with the triumphant temper of physical discovery, enlarges the play of thought in the domain of science, exults in endless development and broad analogies, and, while assuming the forward attitude of our hopes and philosophy, also warns against its dangers. His later poems especially reveal his appreciation of the complexities, subtleties, and difficulties of the more advanced stages of thought and history. Even his colloquial pieces, unrivalled for ease and harmony, as "The Epic," "Will Waterproof's Lyrical Monologue," and "The Talking Oak," have been said to wear the demeanor of modern English society. The repose which marks them appeared in some of his earlier productions as a dreamy, indolent air; and he always prefers, both in the natural and moral world, to paint things at rest, and rarely deals with action. His catholic sympathy with the problems and phases of modern life, as much as his

formal poetical skill and fastidious taste, has made him the favorite poet of the most cultivated and thoughtful. He lived a rather reclusive life for many years in or near London; but latterly, since his marriage, has resided at Farringford, in the Isle of Wight, and receives from the crown beside his salary as laureate a pension of £200. The university of Oxford has created him D.O.L. In person he is of dark complexion and imposing stature and appearance. His poems have passed through many editions both in England and America.

TENOR (Lat. *teneo*, to hold), the second of the 4 parts in harmonical composition, reckoning from the base, or the highest natural and most common of adult male voices, having a general compass from O, the second space in the base, to G, the second line in the treble. The term derives its name from the fact that in the ancient part compositions the tenor sustained or held the plain-song or principal air. The modern practice of giving the air to the soprano or treble is traced to the theatre.

TENREO, or **TANREO**, an insectivorous mammal of the hedgehog family, and genus *centetes* (Illiger). They differ from hedgehogs in having small cutting teeth, in being covered with spiny bristles mixed with silky hairs, and in their inability to roll themselves completely in a ball. The teeth are: incisors $\frac{1}{2}$ or $\frac{3}{4}$; canines $\frac{1}{2}$ - $\frac{3}{4}$, large, conical, incurved, and separated by a considerable interval from the incisors and molars; cheek teeth $\frac{3}{4}$ - $\frac{1}{2}$; the feet are 5-toed, well adapted for digging; ears short and rounded. There are 8 species described, all inhabitants of Madagascar, of which the best known is the silky tenrec (*C. setosus*, Deam.), 10 to 12 inches long, with no tail and a very long pointed snout; the spines are confined chiefly to the head, neck, and back, are yellowish at the root and black in the remaining portion, and the longest not more than an inch; the hair of the sides and lower parts is yellowish and rough. They live in burrows on the water's edge, passing the greater part of the hottest season in a profound sleep, as ordinary hibernating animals do in winter; they are nocturnal in habit, passing much of their time in the water, searching in the mud for their insect food. Though their flesh, like that of most insectivora, is unpleasant to the taste, it is considered a delicacy by the natives.

TENSAS, an E. N. E. parish of Louisiana, bordering on the Mississippi, and drained by Tensas river and Macon bayou; area, 680 sq. m.; pop. in 1860, 16,080, of whom 14,594 were slaves. The surface is low and flat and the soil fertile. The productions in 1850 were 21,665 bales of cotton, and 338,725 bushels of sweet potatoes. There were 3 churches, and 55 pupils attending a public school. It has steamboat communication with the interior by way of the Tensas river. Capital, St. Joseph.

TENT (Lat. *tendo*, to stretch), a portable habitation formed of cloth or skins of animals stretched upon cords or light frames, and sup-

ported by poles set in the ground. Of nomadic tribes, like those of Arabia and the surrounding countries, tents have always been the only habitations. The ancient Hebrews in their wanderings for 40 years through the desert lived exclusively in tents, and frequent allusions to these dwellings are met with in the Old Testament. The nations of the East at an early period brought them to a high state of perfection, and the tents devoted to their sovereigns were fitted up with much magnificence. At the beginning of the Christian era tents appear to have been much used in Judæa, and St. Paul is spoken of as a tent maker (Acts xviii. 3). In the wars of the crusaders the nations of Europe became acquainted with the splendid tents of the Saracens, accounts of which are preserved in the records of that period. Costly furs had also then come into use, and they were employed as a lining, as well as for coverings of tent furniture. Marco Polo found the tents of the khan of Tartary thus fitted out with the richest skins, among which were those of the ermine brought from distant northern countries. In modern times, while tents still continue among barbarous and wandering tribes as their chief dependence for shelter, their use among civilized nations is limited chiefly to military and exploring campaigns.—Though the requirements of tents seem to be very simple, much diversity exists in their forms and manner of construction. In warm and dry climates a mere shelter from the sun stretched upon cords in umbrella form, leaving an open space all around for the circulation of the air, affords sufficient shelter; and the light cloth that forms this cover is easily taken down and transported from place to place. The extension of the sides down to the ground, where they are secured by pins, renders the tent close and better adapted for inclement weather. The great military campaigns of late years have caused much attention to be directed to this subject, and introduced important improvements in tents. The common tent for soldiers was formerly a covering of light duck furnished with two upright poles, to be set in the ground, and a cross pole about 6 feet long extending from one to the other for a ridge; over this the cloth was thrown and drawn out to the ground on each side, and pinned down through loops along the edge. The ends were formed of two triangular pieces, which met and overlapped each other when the sides were drawn out to the proper pitch. These could be closed and tied together, or as usual one end was left partially open with an overlapping flap. The tents used by the French army in the Crimea, up to Oct. 1855, and known as *tentes d'abri*, were wholly of this character, with the exception that the ridge was made by a cord passed from the top of one upright to another, which was then extended down to the ground at each end to brace out the tops of the uprights. For convenience in transporting, the pieces of cloth of which the tents were composed were made

to button upon each other over the edges. A tent of more imposing character is made upon a similar plan, but with vertical sides for about two feet above the ground, and a succession of cords secured to the bottom of the sloping part, affording the means of stretching this out toward pins driven in the ground some distance from the tent on each side. An additional piece of cloth, called a fly, is often attached around the lower edge and drawn out to these pins as a further protection against the weather. Marquees are very large tents of this character, for the use of officers or for hospitals. Those in the English service for the latter purpose weigh altogether 652 lbs., and are 29 feet long, $14\frac{1}{2}$ wide, and 15 high, and should accommodate from 18 to 24 men. The ridge pole is 13 ft. 10 in. long, and is set 13 ft. 8 in. above the ground; the vertical height of the sides is 5 ft. 4 in. Where large camp fires are employed, especially by those exploring in northern forests, a form of tent much used for its convenience and comfort is made by stretching a rectangular cloth from the ridge pole down to the ground on one side, and filling in the triangular opening on the two ends by other cloths of sufficient size attached to the edge of the first piece. The whole front is left open, and the heat of the fire made opposite to it is concentrated and reflected by the top and sides, as in the portable ovens used for roasting. Such tents are sometimes known as "baker tents," and in the western prairies they are called "half-faced camps."—Some of the best models of tents are those that have long been used by the North American Indians, and of which the Comanche lodge is one of the best. Capt. (now Gen.) R. B. Marcy, in his useful little work, "The Prairie Traveller," speaks of it as the usual tenement of the prairie tribes, and of the traders, trappers, and hunters who live among them. It consists of 8 to 10 straight peeled poles about 20 feet long, and when set up overlaid with hides or cloth. Three of the poles are tied together at the small ends with one end of a long line, and are raised upright, the large ends being brought out at the same time to the circumference of the circle that is to form the base of the lodge. The other poles are then set up around the same circle with their tops laid in the forks of the first three, and are bound together by winding the long rope several times around them, and further secured by drawing this down and making it fast to the ground. The covering made to fit this frame is next put around it, and an aperture is left for a doorway where the edges come together at the bottom. A blanket affords a movable cover for this. The lower edge of the lodge is fastened to the ground with wooden pins. The apex is left open with a triangular wing or flap on each side, and that toward the wind is constantly stretched out by means of a pole set into a pocket in the end of it which causes it to draw like a sail and produce a draught from the fire, built upon the ground in the centre of the

lodge. Major H. H. Sibley of the army produced a modification of this in what is known as the "Sibley tent," in which he dispensed with the poles, and used one upright central standard set into an iron tripod. The tent is thus rendered very convenient for packing and travelling. It was used exclusively and with great satisfaction by the army in Utah in their exposed encampment during the winter of 1857-'8. The central pole and tripod within may be dispensed with where the tent can be conveniently suspended from poles or otherwise from the outside. In very cold weather the tent is made more comfortable and roomy also by excavating a basement about 8 feet deep. A great variety of tents have been brought into use for the service of the army in 1861 and 1862; but the general form of the Comanche lodge is still chiefly employed. An important improvement to the Sibley modification of it consists in making the central upright of an iron pipe of 8 or 4 inches diameter, and using this as a smoke pipe for a small sheet iron stove. Warmth and ventilation are thus both provided for.—Cloths prepared with gutta percha or India rubber afford an impervious material for tents, but are too heavy to be much used. A board of army officers have reported favorably of what are called "tent knapsacks" of gutta percha, invented by Mr. John Rider of New York. Pieces of the cloth are prepared 5 ft. 8 in. long and 3 ft. 8 in. wide, with double edges on one side, and brass studs and button holes along two edges, and straps and buckles on the 4th edge. These can be put together to make a large sheet for a tent, and when taken apart each piece serves as an outer covering for the blanket, overcoat, clothes, &c., of a soldier. Four pieces make a sheet 10 ft. 6 in. long and 7 ft. 4 in. wide, sufficient when pitched on a rope 4 ft. 4 in. above the ground to cover a space 7 ft. 4 in. long and 6 ft. 6 in. wide, which will accommodate 5 men, and may be made to shelter 7. Extra pieces of the material may be used with great advantage to spread on the ground as a protection against dampness.—Major Godfrey Rhodes of the British army has published a work on "Tents and Tent Life;" but none of the tents he describes as used by the armies of Europe are thought to be so well adapted for the service required in respect of comfort, salubrity, convenience, and economy, as the "Sibley tent" and its modifications.

TENTERDEN, LORD. See ABBOT, CHARLES.

TENURE (Lat. *tenere*, to hold), in its most general sense, the mode of holding property. In law it is usually confined to the manner of holding land or real property. The doctrine of tenures was once perhaps the most important and the most difficult branch of the law of England; nor has it now wholly lost either its importance or its difficulty.—The first grand division of tenures is into allodial tenures and feudal tenures. Of the word allodial, both the origin and exact original meaning are uncer-

tain. Practically, however, it means a tenure which unites the right of the lord and the right of the tenant, or all right and title to or interest in the land. Hence, one who held land by allodial tenure had full and unencumbered possession of it, with an absolute right to use and dispose of it at his own pleasure, with no control of any one, and no responsibility to any one. The very phrase we use, of allodial tenure, is inconsistent with the views of some writers, who regard an estate held allodially as held without tenure, because they consider tenure as implying the holding the land of a superior. However this may be, an allodial holding stands in direct contrast with a feudal tenure, of which it was the essential quality that a tenant held it of a lord, and that tenant and lord had each their separate rights and interests in it and over it, or, in the language of the law, their separate estates in it. From this characteristic of allodial tenure, it is sometimes said that all the land in the United States is held by this tenure. We doubt the accuracy of this; not merely because all our law of real estate is derived from and permeated by the influence of the feudal tenures, but because the actual condition of land tenure in many at least of the states is better explained by the theory that it is derived from a feudal tenure, and retains many of its characteristic principles.—It seems to be generally admitted, that previous to the prevalence of the feudal system the lands of European nations were held by allodial tenure, and that during the convulsions of the 9th, 10th, and 11th centuries, it became common for holders of land voluntarily to convert their allodial tenure into a feudal tenure, and so hold of some lord. One reason, and probably the strongest, was to obtain his support and protection in return for the allegiance of the tenant; but it may be believed that another cause of this change was the general desire to profit by the opportunity which the feudal system offered of escaping from the disordered and fragmentary condition of society then prevalent. Historians generally agree that this feudal system was nowhere more fully developed or more firmly established than in Normandy. It was therefore a matter of course, almost indeed of necessity, that when William acquired England under a claim of title, but by the power of a feudal army which he carried with him from his own dominions, he should establish his victorious chiefs upon the land their arms had won; and the readiest if not the only way of doing this, was to give them that land to hold upon that feudal tenure and under that feudal system which were admirably adapted to give to the sovereign lord, at any moment, a martial array, that should combine nearly all the available force of the country, and be supported by all its available resources. He divided the land in unequal portions, observing that gradation of rank and of possession which constituted a characteristic feature of the system. While he who received a single manor

became a baron and had his own court, they who received six or more were originally classed as greater barons; and to some of his principal chiefs he gave as many as 700 manors. In this way he divided most of the valuable land of England. His immediate successors followed the same system, and before a century had elapsed the feudal system and the feudal tenures were established over nearly all England. All these tenures rested upon the fee (see *Fee*); but they were very various, and divided the interest in and the beneficiary use of the land, between the lord and the vassal, in very different proportions. There were generally many lords, for the system of subinfeudation prevailed, and the vassal held of his immediate lord, he of the next higher, and he of the next, the series always going up to and ending with the sovereign. Hence we may say that all tenure rested upon two principles: one, that all land was held of the sovereign, who retained certain rights and interests therein; the other, that all the rights and interests of all the lords, and of the tenant finally in possession, added together, constituted that allodial tenure already mentioned. Of the various incidents of feudal tenure, as reliefs, escheats, civil or military services, and the like, we cannot treat in detail; and of the various kinds of tenure, as for example tenure by copyhold, tenure in gavelkind, and the tenure of borough English, we can say but little. Of copyhold there is nothing in the United States. The principal feature of tenure in gavelkind was that all the sons inherited equally and together, instead of the eldest son alone, which latter is the rule of the feudal system, and is nearly universal in England. (See *GAVELKIND*, and *HEIR*.) Of tenure by borough English, the essential principle is, that neither the eldest nor all the sons inherit, but the youngest takes as heir. For this strange custom Littleton accounts by the lesser ability of the youngest son to take care of himself; but a custom prevalent in many parts of the United States offers a more probable explanation of this tenure. It is common in New England, for example, for the eldest son, as he comes to maturity, to receive what assistance his father can give, which is considered as his share of the estate, and with this he goes forth to seek a new home. The same thing is done with other sons as they reach full age; until at length only the youngest son is left to take charge of his parents. When they die he has the homestead; or while they live they relinquish it to him, taking his obligation or trusting to his affection for support. The same custom is said to exist in Bavaria, the Tyrol, and other parts of Germany.—The tenure with which we have most concern is that of socage. This was wholly liberated from the stringent military services which generally prevailed, and the civil services on which such land was held were for the most part easy and honorable. It might be shown, by a historical deduction, that, by a gradual but constant improvement, the present

liberties of England have grown out of the tenure of socage. At an early period it became known as "free and common socage;" and as this tenure spread over the country, the severities, restrictions, and encumbrances of the common feudal tenures passed away, until this process was completed by the statute 12 Charles II. (1661), and nearly all the old feudal tenures (all in fact which were in any way burdensome or restrictive of the proper rights of the tenant) were reduced to the tenure of free and common socage. If it be asked why the change was not carried further, and all feudal tenure abolished, so that all the lands of England might be held as allodial, the answer is, that it was thought the change actually made went far enough to secure all desirable liberty, and cast off all burdens. Such has been the tenure of the lands of England to this day; they are held of the sovereign in free and common socage; and when recently learned and able men were appointed commissioners upon the real law of England, they fully considered the question whether it was now desirable to make this further change, and were unanimously of opinion that it was not. This tenure, they held, has all the actual advantages of allodial ownership. The beneficial use which one who holds by this tenure has in the land, comprises, for all practical purposes, a sole, undivided, and unencumbered interest. Escheat remains as a feudal incident to the tenure; and it is a benefit to the lord; but it is one which he cannot profit by if the tenant has an heir or chooses to make a will. The tenant in fee simple of lands held in free and common socage, can make any disposition of them, and carve any estates out of them, which the law of real estate permits; and any one to whom he grants it by sale or gift, or devises it by will, takes title directly from the grantor or testator, and his title is complete without the consent or concurrence of the lord or any action whatever on his part. It may be added that this tenure, unlike most other feudal tenures, has no reference whatever to the rank or occupation of the tenant, or to the purposes to which the lands are applied. It is certain that this was the tenure created or prescribed by all the early colonial charters or patents from which our titles are now derived, as that of the charter of Virginia in 1606; the patent of New England in 1620; the charter of Massachusetts in 1629; of Maryland in 1632; of the province of Maine in 1689; of Connecticut in 1662; of Carolina in 1662; of Rhode Island in 1663; of Pennsylvania in 1681; the act of the general assembly of the colony of New York in 1691; and the charter of Georgia in 1732. But in New York, Pennsylvania, Connecticut, and Michigan all feudal tenures, including of course that of free and common socage, are abolished by statute; and it seems to be held, that under the provisions of the ordinance of 1787 the doctrine of tenures is not in force in any of the states formed out of the territory to which that ordinance ap-

plied. Substantially, our tenure unites what is best in both the allodial tenure and that by free and common socage. Nor is the fact without its historical value, that the allodial tenure, which formerly prevailed over all Europe, among all the nations who were the ancestors of European nations and so of our own, after being displaced for more than 1,000 years by the feudal system, is at length reestablished in full force throughout the United States. And yet there are reasons for thinking the tenure of free and common socage, freed as it certainly is now from all feudal encumbrance, explains and illustrates our law of real estate better than the other theory. One reason is, that the principles of the feudal system do in fact underlie all the doctrines and all the forms of the common law in regard to real estate; and wherever the common law prevails, which it does in all the states excepting Louisiana (where the municipal law is founded upon the Roman civil law), the principles of the feudal law and of feudal tenure must be understood and made use of. Another reason is, that the law of escheat is universal with us (see ESCHERAT), and it is governed by the law of feudal tenure, modified by our statutes. A third reason is, that the important and universal law of eminent domain is far better understood and applied by the theory that all property is held from the sovereign, that is, the state, or people; and that in the original grant on which all title is founded, the sovereign reserved the right to resume the same for his own, that is, for the public use, on making adequate compensation. Yet another reason is, that the obligation of fealty remains in full force. It is now, and here, an obligation only to the sovereign. It is implied, or rather it is expressed, in the oath of allegiance; but it does not depend on this oath. It is the obligation and the duty, which rest on every citizen of the United States, as the condition upon which he holds all property, all interests, and all rights, to be "faithful and loyal," as the old law expressed it, to be faithful and loyal to his sovereign; that is, to the state and to the Union.

TEOCALLI. See MEXICO, vol. xi. p. 447.

TEOS, an Ionian city, situated on the W. coast of Asia Minor, on the S. side of a peninsula, between the gulfs of Smyrna and Scala Nova, and about 25 m. S. W. from Smyrna. It is chiefly noted as the birthplace of Anacreon, and contained a celebrated temple of Bacchus. It had two good harbors, and was a flourishing commercial town till the Persian conquest, when most of its inhabitants removed to Abdera. The village of Sighajik, which seems to occupy the site of one of the ports of Teos, has walls constructed from its ruins and covered with interesting inscriptions. There are extensive remains of the theatre and other edifices.

TEPHROSIA (Gr. *τεφρος*, ash color, that being the hue of the foliage), a genus of ornamental plants of the order *leguminosae*, with arborescent, half shrubby, or even herbaceous

stems, unequally pinnate leaves, and handsome racemed flowers of a red or pale purplish color. The species are numerous and remarkable, those from Asia for their dyeing properties, and those from America for their narcotic. The *anil* of Ceylon yields a blue coloring matter similar to indigo. A purgative medicine is obtained from a South American species. The poison tephrosia (*T. toxicaria*), native of the West Indies, and the East Indian *T. piscatoria*, are used in capturing fishes by throwing their powdered leaves into the streams. A powerful vermifuge is said to be found in the goats' rue (*T. Virginiana*) of the northern United States, a handsome plant, occurring in dry gravelly soils and in sandy pitch pine plains. This plant has short terminal racemes of white and reddish yellow butterfly-shaped flowers, and is sufficiently ornamental for the garden. Its roots penetrate the soil horizontally to great lengths, and being slender and tough they have acquired for the plant the trivial name of catgut. Five other species are known at the south, with purplish blossoms.

TEPLITZ. See TÖPLITZ.

TEQUENDAMA, FALLS OF. See BOGOTA, vol. iii. p. 426.

TERAPHIM, a kind of household gods or domestic idols mentioned in the early history of the Hebrews. When Rachel left Mesopotamia she took along the teraphim of her father Laban, which she could conceal in her camel's furniture. When David was pursued by the messengers of Saul, Michal, his wife, laid teraphim in the bed in order to deceive the messenger. From the latter passage it is inferred that they must have borne some resemblance to the human figure. It also seems that they were consulted by the idolatrous as oracles. Nothing more is known concerning them.

TERATOLOGY. See MONSTER.

TERBURG, GERARD, a Dutch painter, born in Zwolle, in the province of Over-Yssel, in 1608, died in Deventer in 1681. In early life he visited Italy, and, after a sojourn of several years in Paris, settled in Holland and rose to great eminence as a painter of conversation pieces, musical parties, ladies at their toilets, and other compositions of the kind known as genteel life. In 1648 he painted a picture of the plenipotentiaries assembled at the congress of Münster, which, though only 17 inches by 22, was sold in 1887 for nearly \$9,500. The reputation acquired by this work led to his being invited to Madrid, where he was much employed by the king, who knighted him, and by the chief nobility. He was less correct in drawing or composition than several of his contemporaries, but excelled nearly all of them in color and the finishing of his draperies. No other artist ever painted white satin dresses with such exquisite skill. His pictures, though for the most part of cabinet size, bring high prices.

TERCEIRA, one of the Azore islands, situated near the centre of the group; extreme

length 20 m., average breadth 18 m.; pop. 40,000. Angra, the capital (lat. 38° 30' N., long. 27° 10' W.), gives its name to a department composed of the three islands of Terceira, St. George, and Graciosa. The coast is nearly everywhere bold and precipitous, and the surface of the interior is undulating and rises gradually toward the centre, where it becomes mountainous. The summits of the mountains consist mostly of fertile plains, and are not peaked like those of the other islands of the group. Many of the mountain masses are composed of soft pumice, and several destructive landslips have occurred. The island is well watered, and the soil, which consists principally of decomposed lava, is particularly fertile. Its exports of oranges and lemons amount to 20 per cent. of the whole quantity shipped from the Azores. Terceira was the seat of the Portuguese regency during the usurpation of Dom Miguel.

TERCEIRA, count of Villafior, duke of, a Portuguese general and statesman, born in Lisbon, March 10, 1792, died there, April 26, 1860. He entered the military service at the time of the French invasion. In 1826 he declared for the constitutional charter granted by Dom Pedro, and upon the resignation of that monarch espoused the cause of Maria da Gloria. Made major-general, he defeated and drove to the frontiers of Castile the troops of Dom Miguel. He was made a marshal, but when in 1828 Dom Miguel became regent, he was forced to seek an asylum in England. When the constitutional party raised its banner in Oporto in the same year, he returned, but was obliged to flee a second time. The following year he rejoined the insurgent patriots at the island of Terceira, was made commander-in-chief of the constitutional army, at the head of which he conquered the Azores, and subsequently, transferring his operations to Portugal, ended the rule of Dom Miguel in 1834 by the capitulation of Evora. He now entered the ministry of Palmella, but resigned in 1836, and in 1837 was obliged to leave Portugal once more. Returning, he became minister of war in 1842, and in the insurrection of 1846 he was taken prisoner by the insurgents, but was soon restored to liberty and again became minister. In 1858 he was sent to Germany to conduct to Portugal the princess Stephanie of Hohenzollern, the affianced bride of the king. At the time of his death he was minister and president of the council.

TEREDO. See SHIP WORM.

TERENCE (PUBLICUS TERENTIUS AFRE), a Roman comic poet, born in Carthage about 195 B. C., died about 159. He became a slave of P. Terentius Lucanus, a Roman senator, who gave him an excellent education, and finally freed him. The *Andria* was the first play written by him, and on offering it for representation the curule ædiles referred it to Cæcilius Statius, who immediately detected the genius of the unknown author. The play was not acted, however, until 166, and its success introduced him into the best society of Rome, Lælius and the younger

Scipio being among his associates. Later in life he went to Greece, and while living in that country translated 108 of Menander's comedies. The manner of his death is uncertain, though the common account was that he died of grief in consequence of the loss of all his translations of Menander. Six of his comedies are extant, and for aught we know they are all that he wrote. Beside the *Andria* ("The Woman of Andros"), the plot of which was adopted by Steele in his "Conscious Lovers," there are *Hecyra* ("The Stepmother"), produced in 165; *Heauton-Timoroumenos* ("The Self-Tormentor"), produced in 168; *Eunuchus* ("The Eunuch"), the most popular of his plays, and for which he received the unusual sum of 8,000 sesterces, produced in 169; *Phormio*, produced the same year; and *Adelphi* ("The Brothers"), acted first in 160. The dramas of Terence all belong to the *fabula palliata*, and with the exception of the last two were first performed at the Megalesian games. The plots of his plays were borrowed from Menander; but his Latinity is elegant, and his works have been handed down to our time in a very correct state. There have been numerous imitations of his dramas by the moderns, among whom may be mentioned La Fontaine, Molière, Cumberland, and Garrick. His comedies have also been translated into nearly all the languages of modern Europe. The first edition of them is probably that of Milan (fol., 1470); the last is that of Volbehr in 1846. A translation of his poetry into English blank verse was made by George Colman (4to., London, 1765).

TERMINUS, in Roman mythology, a deity who represented an attribute of Jupiter, or who was Jupiter solely as the protector of boundaries. The origin of his worship was attributed to Numa, who ordered that every one should mark the boundaries of his land by stones consecrated to Jupiter Terminus, and should offer upon them every year at the festival of the *terminalia* sacrifices of cakes, meal, and fruit. This law also applied to the state; but the public termini were neglected in the later period of Roman history, while the termini of private property long retained their sacred character. A terminus stood in the temple of Jupiter in the capitol.

TERMITES, the proper name of the white ants, or the neuropterous insects of the family *termitinae*. Though they resemble the common ants (*formica*) in their social habits, they belong to a different order, and in many respects come near the orthoptera. In the genus *termes* (Linn.) the antennæ are thread-shaped, with about 20 joints; the eyes small but prominent, and the ocelli 3; the mouth as in orthoptera; thorax distinct, and wings large, long, and membranous; legs short with 4-jointed tarsi; abdomen with a pair of minute caudal appendages. They live in vast communities, principally in the tropics, and do great damage by devouring every thing but metals and stone which comes in their way, gnawing even the

interior of the beams of houses, leaving only a thin shell to conceal their operations. According to Latreille there are 5 classes in their communities, males, females, workers, neuters, and soldiers. The males and females are at first exactly alike, and are furnished with 4 very long, nearly equal wings; after impregnation the abdomen of the female increases greatly in size from the immense number of eggs which it contains; as many as 80,000 may be laid by one female in 24 hours, making about 80,000,000 in a year. Most of the community is made up of wingless individuals, resembling the winged insects, but without eyes; these are the workers, which perform all the labors of construction. Others without wings, apparently pupæ, resemble the workers; but have 4 tubercular wing cases on the thorax; these are supposed to be neuters or incomplete females, which attend upon the king and queen and take care of the young brood; the extraordinary fecundity of these ants renders necessary a large class of neuters, which possess the affections of maternity without the power of reproduction. The 5th class, apparently neuters still further developed, have very large jaws, and are the soldiers and defenders of the rest. The constitution of their societies in its general characteristics does not vary essentially from that noticed under ANT. They make edifices of a most remarkable size and complexity, usually on the ground, but sometimes among branches of trees and in houses communicating with the ground by long spiral galleries. When on the ground, the most usual shape is that of a group of irregular cones, frequently 12 feet high, looking like huts of the natives, and so firmly constructed that man and beast can stand on them securely; human works, to be of the same relative size, would tower 5 or 6 times above the Egyptian pyramids, with a base large in proportion; they are built of earth softened in the jaws of the workers, which dries quickly and becomes very hard. A nest is divided internally into numerous chambers and galleries, in one of which the queen is imprisoned, and waited upon in the most attentive manner by numerous special attendants whose apartments are in close proximity to the royal cell; the male is said to lie concealed under one side of the enlarged abdomen of the female. The attendants carry off the eggs as soon as they are laid into separate chambers, where the young when hatched are carefully tended by the nurses. There are generally 2 or 3 roofs within the dome-shaped interior, and the thick walls are perforated by passages leading in various directions to the nurseries, magazines of food, ground floor, and subterranean entrances; the food consists principally of decaying and dried wood, though gums and thickened vegetable juices are stored in their magazines. The different members of the community all seem to know their duty, and perform it without being ordered; the king and queen have no regal authority, and

no part of the community is ruled by another; there is in their nests a perfect system of willing coöperation for the general good. Destructive as the termites often are, they play a most important part in the economy of nature by removing decaying wood, which otherwise in a short time would seriously interfere with vegetation in the tropics.—The largest and best known species is the warrior white ant of Africa (*T. fatalis*, Linn., or *T. bellicosus*, Smeath.); in each nest there are a king and queen, and about 100 workers to 1 soldier; the workers are about $\frac{1}{4}$ of an inch long, always busy and very fast runners; the soldiers, which appear to be the same further developed, are about half an inch long, and the perfect insects from $\frac{1}{8}$ to $\frac{1}{4}$ of an inch long; it is supposed that 2 or 3 years are requisite for the full development of the species from the egg. Toward the commencement of the rainy season the perfect insects take flight, but are mostly destroyed by the heavy rains; if a pair escape, they are taken by some of the workers which are always running over the ground, and are made the king and queen of a new colony. The pregnant female has the abdomen 8 to 5 inches long and $\frac{3}{4}$ of an inch wide, about 2,000 times as large as the rest of her body, and 20,000 to 30,000 times as large as that of the workers. The bite of the soldiers is very severe and painful, but not dangerous to a healthy person; they are so savage that they permit themselves to be torn asunder rather than let go their hold. They have many enemies in other ants, birds, and reptiles, which destroy great numbers; the wingless ones are also devoured with avidity by the natives and even by Europeans, who roast them in the manner of coffee, and consider them delicious, nutritious, and wholesome. The *T. mordax* and *T. atrox* of Smeathman, also African, build turret-shaped nests, with a top like the head of a mushroom; the *T. arborum* (Smeath.), of Africa, makes its nest on the exterior of trees, and in the roofs and walls of houses, rendering the latter, except where they fill up with a kind of plaster as they excavate the wood, mere shells and liable to fall from slight causes. For full details on the habits of the white ants the reader is referred to "Insect Architecture," by James Renie, in the "Library of Entertaining Knowledge" (London, 1880-'81).—There are other species in tropical Asia, and even 2 or 3 in southern Europe. The *T. lucifugus* (Rossi) builds in trees, especially in the interior of oaks and pines, and has been in some years very destructive to the frames of houses in the southern parts of France; it may be destroyed by sulphurous and chlorine gases forced into the galleries. The *T. flavicollis* (Fabr.) has in like manner proved injurious to the olive trees in Spain. In the United States a representative species, the *T. frontalis* (Haldeman), has been noticed at Salem, Mass., where it did considerable mischief in greenhouses and graperies, not only attacking decaying and dead wood, but

also excavating the roots of living vines and causing their destruction. (See "Proceedings of the Boston Society of Natural History," vol. vii. pp. 287, 288, May 2, 1860.)

TERN, the proper name of the birds of the gull family and sub-family *sternina*, among which is included the noddy, previously described. The terns have a rather long, usually slender, nearly straight, and sharp-pointed bill; wings elongated, with long and pointed primaries; tail long, and in most species forked; tarsi slender, anterior toes with a deeply notched web, hind toe small, and the claws curved and sharp. They are found on and near the sea shore, and sometimes on inland lakes and rivers, most of the time hovering with rapid and easy flight over sandy bars and shallows, darting suddenly upon the small fishes and crustaceans on which they principally feed; they are often seen swimming and resting on the water, but never diving; from their forked tail, small size, and swift and graceful flight, they are popularly called sea swallows.—In the typical genus *sterna* (Linn.) the upper mandible is slightly curved, with the frontal feathers extending to the nostrils; the outer quill is the longest. It contains more than 60 species in both hemispheres, migrating in bands from place to place according to season; the eggs are 2 to 4, usually deposited in a slight hollow in the sand on rocks surrounded by the sea: the hatching is left mostly to the sun, the females sitting only at night and in cold weather; the young are carefully fed and bravely defended. The largest species is the Caspian tern (*S. Caspia*, Pall.), 21 $\frac{1}{2}$ inches long, 51 in alar extent, with a very stout bill of 3 inches; the back and wings are pale bluish ash, the upper parts of the head black with a greenish gloss, the quill shafts and the under plumage pure white, the bill vermillion, and the legs and feet black; the tail is not much forked; the young are mottled above with blackish brown. It is found in the United States from the coast of New Jersey northward, and all over Europe, in the vicinity of the Caspian sea (where it was first found and described by Pallas), and also in Africa. The eggs, as in most of the terns, are yellowish stone-colored, with ash-gray and dark reddish brown spots; they are 2 $\frac{1}{2}$ by 1 $\frac{1}{2}$ inches. The Cayenne or royal tern (*S. Cayana*, Bonap.) is 21 inches long and 49 in alar extent, with a deep red bill of 2 $\frac{1}{2}$ inches; the mantle is bluish gray, lower parts white, legs and feet black, and the tail forked. It is found on the Atlantic coast from Labrador to Florida, being abundant about the southern keys; it also occurs in California. It is a very shy bird, and utters loud and harsh cries during flight; when any are killed out of a flock, the rest dart toward the gunner, affording a fine chance for a second shot; when wounded they eject the contents of the stomach, and bite severely; the eggs are 2 $\frac{1}{2}$ by 1 $\frac{1}{2}$ inches, and like those of the other species afford good eating; the flesh is very oily. The marsh tern (*S. arvensis*, Wils.)

is 18½ inches long and 84 in alar extent; the bill is 1½ inches, and, with the head above, is black; mantle pale bluish gray; lower parts white; tail moderately forked. It is found on our coast as far north as Connecticut; it is a very powerful flier and a buoyant swimmer; the food consists principally of insects caught on the wing, as by the swallows; the eggs are 1½ by 1 inch, olivaceous with dark blotches and dots. The old world representative of this species is the gull-billed tern (*S. Anglica*, Mont.), which is distributed over central Europe, and also in India and N. Africa; it is regarded as the same species as the marsh tern by most of the older ornithologists. The sooty tern (*S. fuliginosa*, Gmel.) is 16½ inches long and 35 in alar extent; bill 1½ and black, as are the legs and feet; it is deep black above, the forehead and lower parts white; tail deeply forked, black, with the outer and basal half of the inner web of the outside feathers white. It is found in the gulf states from Texas to Florida, arriving from the south in May and departing by the beginning of August; it rarely alights on the water, where it would be incommoded by its long tail; it feeds principally on fish, which it seizes by a sweeping curve and not by the headlong plunge of most terns; it sometimes hovers over the water to pick up floating particles like the petrels; the cries are very loud when the breeding places are disturbed; the eggs are 8 in number, 2½ by 1½ inches, and afford delicious eating, and in former times were the source of a considerable trade with Havana. Wilson's tern (*S. Wilsoni*, Bonap.) is 15 inches long, with an alar extent of 82; the bill is 1½, slender, coral red, black near the end with a yellow tip; mantle light grayish blue; upper part of head and neck deep black; beneath pearl gray; tail deeply forked, with the outer web of lateral feather blackish gray; legs and feet coral red. It is found from Texas to Labrador, and on the coast of Massachusetts goes by the name of mackerel gull, from the supposition that it announces the arrival of this fish in its summer quarters; it formerly bred on Egg Rock near Nahant, and 25 years ago was very abundant in summer on Nantasket beach; the eggs are 3 in number, 1½ by 1½ inches. Its European representative is the common sea swallow (*S. Airundo*, Linn.), spread over Europe and Africa; it is 14½ inches long, and the eggs 1½ by 1½ inches. The arctic tern (*S. arctica*, Temm.) is 14½ inches long, and 82 in extent of wings; the bill 1½, slender, and deep carmine; mantle light grayish blue, and under parts plumbeous gray; tail very deeply forked; legs and feet crimson. It is found from the coast of New England to the arctic seas and the fur countries, also coming down to N. Europe; it is a very rapid and graceful flier, dashing boldly into the water after fish and shrimps; the eggs are delicious eating, 1½ by ½ of an inch. The roseate tern (*S. paradisea*, Brunn.) is 16 inches long and 80 in alar extent; bill 1½, slender,

der, brownish black, orange at the base; mantle pale bluish gray; under parts white with a roseate tinge; tail very deeply forked; legs and feet orange. It is found from Florida to New York, and also in Europe and Asia; it is noisy and restless; the roseate hue of the breast disappears soon after death; it breeds in Florida, in company with other species; the eggs are 1½ by 1½ inches. The least or silvery tern (*S. frenata*, Gambel) is 8½ inches long and 19 in alar extent; bill 1½, slender, pale orange red; mantle bluish gray; under parts silvery white; legs and feet like bill; tail forked. It is found from Texas to Labrador, and on the western rivers and great lakes. This delicate species seizes insects on the wing like the swallows and flycatchers, and feeds also on shrimps; it is the least shy of the terns, and utters a sharp and frequently repeated cry like the notes of the barn swallow when disturbed; the eggs are 1½ by 1 inch. Its European representative is the *S. minuta* (Linn.). A common species in Europe is the Sandwich tern (*S. Boysti*, Lath., or *S. cantiaea*, Gmel.), 15 inches long; the bill black, with a yellowish white tip; the head above the eyes black, and the occipital feathers elongated; mantle ash-gray; under parts and tail white; legs and feet black. It is found throughout Europe, being a summer visitor in Great Britain, and migrating south into Africa; the eggs are 2 by 1½ inches, yellowish stone-colored, with ashy, orange, or deep red and brown variable markings. This species is represented in America by Cabot's tern (*S. acutifluida*, Cabot), found along the gulf states from Texas to Florida.—The short-tailed or black tern (*hydrochelidon plumbea*, Boie) is 9½ inches long and 24 in alar extent; the bill is 1½, strong, brownish black; head, neck, breast, sides, and abdomen black; lower tail coverts, shafts of first 4 primaries, and edge of bend of wing, white; back, wings, and tail dark plumbeous gray; legs and feet reddish brown. It is found from Texas to New England, in the fur countries, and on the Mississippi and its tributaries; it goes more inland than the other terns, and its food consists chiefly of neuropterous insects which it catches like a swallow; it also feeds upon the fry of fish and aquatic worms; the tail is not forked, but slightly notched; the nest is made in a tuft of flags or grass just above the surface of the water or on the floating leaves of aquatic plants; the eggs are 2 to 4, 1½ by 1 inch, and are constantly covered by each sex in turn. Its European representative is the *H. nigra* (Boie).

TERNAUX, GUILLAUME LOUIS, baron, a French manufacturer, born in Sedan, Oct. 8, 1768, died in St. Ouen, April 2, 1838. When scarcely 16 years old he was intrusted with the management of a woollen factory belonging to his father, and by it retrieved the fortune of his family. A supporter of reform in 1789, he was at the same time devoted to the king, and was one of his defenders in 1793. He emigrated in 1793, but returned on the fall of

Robespierre, and established large manufactories at Louviers and Sedan; and though he did not conceal his opposition to the consulate and the empire, Napoleon made him a member and officer of the legion of honor. He naturalized Thibetan goats in France, manufactured shawls in imitation of the Indian ones, which were styled *cachemires-Ternaux*, and made a series of interesting experiments as to the means of preserving corn in underground vaults. He was made a baron by Louis XVIII.; in 1818 he was elected a deputy by the 2d district of Paris; and being returned again in 1827, he was one of the 221 deputies who brought about the revolution of July, 1830. The commercial crisis which followed was a deadly blow to his prosperity, which had been already impaired in 1823 by the law taxing raw materials. He however paid all his debts, and died impoverished.—His nephew, HENRI TERNAUX, who has taken the additional name of COMPAÑS, is remarkable for his devotion to the study of American history. He has published 2 series, in 10 vols. each, of *Voyages, Relations et Mémoires*, from inedited Spanish MSS., relating to the discovery and conquest of America, and characterized by Mr. Prescott as "invaluable" (Paris, 1836-'40); *Bibliothèque Américaine*, 1498-1700 (8vo., Paris, 1837); *Bibliothèque Asiatique et Africaine* (1841-'2); and various other works.

TERNI (anc. *Interamna*), a walled town of central Italy, in the district of Spoleto, beautifully situated on an island formed by the river Nera, 49 m. N. by E. from Rome; pop. 9,245. It is the see of an archbishop, and the cathedral is a fine building with a magnificent altar. The place has many remains of antiquity, including some vaults of an amphitheatre constructed in the time of Tiberius, portions of temples of Sol and Cybele, and some parts of public baths. The surrounding country is exceedingly productive, and there are oil and flour mills on the river. Woollen and silk goods and leather are manufactured. About 5 m. from Terni are the celebrated falls of the Velino, known in the neighborhood by the name of Cascata del Marmore. They are artificial, having been constructed by the Romans, and the water is brought to them by a channel cut in order to drain the plains of Rieti. The height of the fall is nearly 840 feet, and the bed of the channel immediately above them about 50 feet. The water descends by 8 separate leaps, the first of 50, the second of about 550, and the third of 240 feet; the whole forming one continuous sheet of foam, said by Byron to be "worth all the cascades and torrents of Switzerland put together."

TERPANDER (Τερπανδρος), a Greek musician and poet, born at Antissa in the island of Lesbos, flourished in the earlier half of the 7th century B. C. He removed, early in life apparently, from Lesbos to Sparta, where in 676 he was crowned victor in the first musical contest at the feast of Apollo Carneius, and where he established the first musical school or system

that existed in Greece. He enlarged the compass of the lyre from a tetrachord to an octave, but with the omission of the third string, making it really a heptachord; and he was the first who regularly set poetry to music. His names remained for a long period the standard melodies used at religious festivals, and his school long flourished at Sparta.

TERPSICHOIRE, one of the nine Muses, daughter of Jupiter and Mnemosyne. She presided over choral song and dancing, and is generally represented as crowned with flowers and holding a lyre and plectrum.

TERRA, or TELLUS, a goddess of the Roman mythology, in whose form the earth was personified and worshipped, and who is thus often named in contrast with Jupiter, the god of heaven. A festival in her honor was celebrated on the 15th of April, and private sacrifices were offered to her at seedtime and harvest, and also when any member of a family died, as Terra was to receive the departed into her bosom. Terra corresponds to Gæa or Ge in Greek mythology. In the Hesiodic theogony Gæa was the first born of Chaos. She gave birth to Uranus, whom she afterward married, and from this union sprang the Titans, the Cyclops, and the hundred-handed giants. Her worship seems to have been universal among the Greeks, and the epithets applied to her have in all cases some reference to the earth as the all-sustaining and all-producing mother.

TERRA COTTA (It., baked clay), an earthenware, mention of which is made in the article POTTERY, as having been produced by the ancient Egyptians and Greeks in the forms of vases, water jars, various ornamental figures, &c. The material selected for this ware is of clay of considerable purity, and the articles are generally slack-baked, sometimes merely hardened by continued exposure to the sun. The color is usually a red or buff, and the vases are often ornamented with designs of leaves, vines, &c., painted in black, and sometimes in other colors. While these adorn the rim, neck, and stand, the body is sometimes covered with allegorical representations of gods, men, and animals. The Romans appear to have employed finer materials for their terra cotta, and to have moulded these into lamps, urns, &c., which they ornamented by depressed or raised figures. From the 12th to the 17th century terra cotta was much used in Italy for architectural decorations, and Michel Angelo and other sculptors employed it for their models and clay sketches. The manufacture of decorative works in terra cotta became an important branch of industry in England in the latter part of the last century. The mixtures employed were of pure clays and fine quartz sand or calcined flints with pulverized potsherds or old pottery. The old coats of arms seen over many of the shop fronts in London were moulded and baked in this material. It was also used for statues, and decorative pieces of various forms were employed in different parts of

buildings. The ware was much more firmly baked than that of the ancients. Of late years it has been employed for elaborate architectural ornaments, such as are ordinarily carved in stone, and also for architectural models. Drain tiles and similar ware are made of it.

TERRA DEL FUEGO, or **TIERRA DEL FUEGO** (Sp., "Land of Fire"), a group of islands which lie off the S. extremity of South America, between lat. $52^{\circ} 40'$ and 56° S. and long. $63^{\circ} 40'$ and 75° W. It is separated from the mainland by the long and intricate strait of Magellan, and has the Pacific ocean on the W. and the Atlantic on the E., while the E. and W. limits of these seas are supposed to meet at Cape Horn, its S. extremity. The group comprises numerous small islands, of which Cape Horn is the most remarkable; the large island of East Terra del Fuego or King Charles South Land, which is about 800 m. long E. and W. and 200 broad; the islands of Navarino and Hoste to the S., separated from the last named by the Beagle channel; and Clarence and Decepcion islands to the W. All these islands are deeply indented by arms of the sea, and of very irregular shapes. They are mountainous, and many of the mountains are more than 5,000 feet high, while the highest summit reaches an elevation of about 7,000 feet. The limit of perpetual snow is about 4,000 feet. The soil is generally a swampy peat, and to the height of 1,500 feet is covered with stunted forests of beech. The geological formation is principally clay slate, greenstone, and granite. The climate is one of the worst in the world; storms, sudden gusts of wind, rain, snow, and mist constantly succeed each other. The sea weed called *fucus giganteus* is exceedingly abundant upon the coasts, and affords shelter for innumerable shell fish, without which the natives would find it extremely difficult to subsist. Deer, guanacos, foxes, sea otters, mice, and bats are the only animals found; but birds, particularly sea fowl, are numerous.—The natives of the N. E. part of Terra del Fuego bear a strong resemblance to the Patagonians, while those of the S. E. portion of the group are short, ill made, and ill looking. Their only clothing consists of guanaco or seal skin. They are filthy in their habits, and will eat any flesh however putrid. Their huts, generally built close to the sea shore in some sheltered spot, are of a conical shape, made of branches or small trees stuck in the earth, about 7 or 8 feet in diameter and 4 or 5 feet in height, with a small hole for a door.—Terra del Fuego was discovered by Magalhaens in 1520, and received its name from the numerous fires seen during the night along the shore.

TERRAPIN, a name commonly applied to several species of land tortoises, but in the United States generally limited to the few fresh water species of the family *emydoida*, extensively used as food. They have a depressed head, and the neck can be wholly retracted within the shell; eyes large, and the beak

somewhat like that of a bird of prey; they are good swimmers, and out of the water move with more quickness than the land tortoises; their food consists of small reptiles, fish, and other aquatic animals, though in captivity they eat vegetables readily.—The yellow-bellied terrapin (*trachemys scabra*, Ag.; *emys serrata*, Daud.) is 12 inches long, $7\frac{1}{4}$ wide, and about 11 high; the shell is rounded, very convex, wrinkled longitudinally, and rough all over. The color is blackish brown with yellow lines and marks more or less radiating; sternum yellowish, notched behind; snout short and pointed; upper jaw with a very slight notch; eyes large, with golden iris having a broad black stripe extending horizontally through it; fingers 5, each with a short strong nail, and toes 5, fully webbed, 4 only having nails; tail short, thick, and pointed; head and limbs black, varied with yellow lines, a broad transverse band of the latter across the neck behind the eyes. This species lives in stagnant ponds and pools, and is fond of basking in the sun on the margins and on stones and stumps, whence it can readily plunge into the water if disturbed; it is found from Virginia to Georgia, south of the latter being replaced by the Florida and north of the former by the red-bellied terrapin; it is abundant about Charleston, S. C., where it is seen in great numbers in the markets; the flesh is considered very good.—The red-bellied terrapin or potter (*ptychemys rugosa*, Ag.; *E. rubriventris*, Leconte) is 11 inches long, 7 wide, and about 6 high; the shell is entire in front, widest and notched behind; upper jaw deeply notched, and the lower serrated with 8 teeth in front; shell, head, neck, and limbs dusky brown, with blotches, spots, and lines of red; sternum dusky red. It lives in running waters, preferring a rocky bottom; it is found between the Delaware river and Chesapeake bay, and is abundant about Trenton, N. J.; it is common in the Philadelphia markets, but its flesh is less esteemed than that of the preceding and following species.—The Florida terrapin (*P. concinna*, Ag.; *E. floridana*, Harlan) is the largest of the species, being 15 inches long, 10 wide, and $7\frac{1}{4}$ high; the shell is entire, compressed on the sides; the jaws without teeth, the lower somewhat serrated; the shell, neck, head, and limbs brownish, with numerous yellow lines and bands; sternum pale yellow, the marginal plates with a black spot having a yellow centre; throat ashy, striped with yellow. It is extensively distributed through the southern states, in lakes and rivers, from North Carolina as far as western Louisiana, and up the Mississippi valley to Arkansas; it is very common in E. Florida, especially in the St. John's river; its flesh is delicious. An allied species, the Alabama terrapin (*P. mobiliensis*, Ag.; *E. mobiliensis*, Holbr.), is very large, measuring 15 inches in length, $9\frac{1}{4}$ in width, and 6 in height; the shell is very high on the anterior part of the back, and somewhat serrated be-

hind; jaws serrated, the lower hooked; sternum notched behind; above, on the head, neck, and limbs, dusky brown, with a network and longitudinal lines of yellow; sternum yellow, with a black blotch on each marginal plate. It is found in Alabama, Mississippi, Louisiana, Texas, and Mexico; it is abundant about Mobile, where its flesh is considered a great delicacy.—The chicken terrapin (*deirochelys reticulata*, Ag.; *E. reticulata*, Schweig.) is 9½ inches long and 5½ wide; the shell is oval, entire, longitudinally rough; upper jaw slightly notched, lower entire with a hook in front; neck very long; above, head, neck, and limbs dark brown, with numerous yellow lines communicating so as to form a network, whence the specific name; lower parts yellow, with black spots on some of the marginal plates. The habits are the same as in the other species, the long neck giving them in the water somewhat the appearance of a snake, as they swim with this part and the head alone visible above the surface. It is found from North Carolina to Georgia and Louisiana, not far from the sea coast; it is often brought to market, and is the most esteemed of the terrapins for food.—The salt water terrapin (*malacoclemmys palustris*, Ag.; *E. terrapin*, Holbr.) is 7½ inches long and 8 high; the shell is nearly entire, slightly notched posteriorly; the head is very large; jaws strong and cutting, the upper slightly notched and the lower hooked; eyes small with a gray iris; neck short and thick. The color is dusky olive green, with darker concentric lines; sternum generally yellowish with concentric dusky lines; side of the head, neck, and limbs brownish white with innumerable black dots; the males are the smallest and have deeper striae. It lives in salt water and in salt marshes, where it hibernates; it is very shy, a rapid swimmer, and a quick runner on land; it is found from Rhode Island to Florida, along the gulf of Mexico, in South America, and perhaps in the West Indies; it is abundant about Charleston, S. C., and great numbers are taken when the female is about to lay her eggs in spring and early summer; the flesh is excellent, and in the middle states most esteemed during the period of hibernation.

TERRE BONNE, a S. E. parish of Louisiana, bordering on the gulf of Mexico, and drained by the Terre Bonne, Black, and Caillon bayous; area, 1,640 sq. m.; pop. in 1860, 12,090, of whom 6,784 were slaves. The surface is flat and marshy, and diversified by numerous shallow lakes. The productions in 1850 were 187,420 bushels of Indian corn, 9,171 hogsheads of sugar, 435,200 gallons of molasses, and 466,900 lbs. of rice. There were 3 churches, and 270 pupils attending public schools. The New Orleans and Opelousas railroad intersects the north part of the county. Capital, Houmas.

TERRE HAUTE, a city and the capital of Vigo co., Ind., on the E. bank of the Wabash river, 78 m. W. S. W. from Indianapolis, and 69 m. N. from Vincennes; pop. in 1850, 4,051;

in 1860, 8,594. It is beautifully situated on an elevated plateau, is well built, and has broad streets tastefully ornamented with shade trees. It is the centre of trade for a rich and populous region. It has a number of manufacturing establishments of various kinds, among which are railroad machine shops for repairing and constructing cars. Its trade is chiefly in produce and pork; the average number of hogs slaughtered per annum for 10 years ending with 1857 was over 66,000. The Terre Haute, Alton, and St. Louis railroad connects it with St. Louis; the Terre Haute and Richmond railroad with Indianapolis; and the Evansville, Vincennes, and Terre Haute railroad with the Ohio river; and it is connected with Lake Erie by the Wabash and Erie canal. The Wabash river is navigable a portion of the year for steamboats, and shipments are made direct to and from points on the Ohio and Mississippi rivers. The national road and other excellent roads intersect the county. Terre Haute has a handsome court house and other public buildings, 8 banks with a capital of \$500,000, 4 fine public school buildings, several private schools, St. Vincent's academy for girls, under the supervision of the sisters of Providence of St. Mary's, a female college, and 18 churches, viz.: 3 Methodist, 2 Presbyterian, and 1 each Baptist, Christian, Congregational, Episcopal, German Methodist, German Reformed, Roman Catholic, and Universalist. There are 8 daily and 3 weekly newspapers, and 2 public libraries. An abundance of bituminous coal is found near the city. Terre Haute was laid out in 1816.

TERRELL, a new S. W. co. of Georgia, drained by affluents of Flint river; area, about 800 sq. m.; pop. in 1860, 6,237, of whom 2,892 were slaves. Capital, Dawson.

TERRESTRIAL MAGNETISM. See MAGNETISM, TERRESTRIAL.

TERRIER (*canis terrarius*, Flem.), a small variety of domesticated dog, so named from its propensity to pursue and attack its prey in subterranean retreats. It is considered by Hamilton Smith as descended from an indigenous European canine, and certainly combines the innate courage, sagacity, and external peculiarities perpetuated without care in breeding, which indicate a primitive stock. The terrier in England, if not indigenous, was very early introduced by the primitive inhabitants; even a considerable mixture with other breeds does not impair its boldness, hardness, fidelity, vivacity, and vermin-hunting propensities. There are two well marked varieties, the result of fancy or accident. One is smooth, rounded, elegant in shape, usually black, with tan spots over the eyes and the same tint on the legs and lower parts; it is occasionally white; the nose is sharp, eyes bright, ears pointed or slightly turned down, and the tail carried high and bowed over the back. The other, the Scotch terrier, the oldest and purest breed, has shaggy and wiry hair, a shorter and fuller muzzle, bearded snout and face, stouter limbs, less ele-

gant form, and a pale sandy or ochrey color; it is sometimes white. The tale of Skye breed is one of the most prized, and one of the ugliest. The terrier has an acute sense of smell, and is a good attendant on a pack of hounds, forcing foxes and other game from their coverts and dens; it is a determined enemy of the weasel, badger, and rat families, and is therefore very useful about the house and farm; its boldness is very great, and it has been noticed in India that, when even the bulldog pauses, the English terrier does not hesitate to attack the larger carnivora and worry them from their hiding places; the jaws are very powerful, one bite sufficing to kill a rat. The Scotch terrier has been known to kill 100 rats in a room in less than 7 minutes. In England the terrier blood is visible in most of the sheep and cattle dogs; but the most prized variety is the bull terrier, from a cross with the bulldog, the most determined, pugnacious, and savage of the dog tribe; it is this which affords material for the dog fights so attractive to the lower orders of large cities, in which neither combatant surrenders while life remains, and in which the most frightful wounds are received without a groan; in this the ears are pointed, and the general characters are those of the bulldog; it is usually white, with some black about the head. There is a large and rough breed in Germany, probably a cross with a large shepherd's dog, bold, strong, and noisy, used to arouse wild boars and other fierce beasts, and bring them within reach of the hunters; it is of a wolf-gray color, whitish about the head and breast, with a well fringed tail curled over the back.—The turnspit is a cross of the terrier with larger and less pure breeds; the body is long and heavy, with disproportionately short and generally crooked legs; it is bold, vigilant, and spirited, and, though of larger size, is used in Europe for the purposes of the terrier; it is, when best, a cross with a hound; it received its name from its being in old times employed to turn the spit in the kitchen, walking round in a kind of wheel. The *C. vertagus* of the ancients, sometimes erroneously translated turnspit, is the lurcher, a degenerate greyhound.

TERTIARIANS (Lat. *tertiarius*, containing a third part), a name denoting side branches of a number of religious orders in the Roman Catholic church, whose members do not live in common in cloisters and convents, but bind themselves by simple vows to the observance of certain prayers and exercises of the order. Such an organization of secular persons occurs for the first time in the history of the Premonstratenses, and another was connected with the order of the Templars. But it did not become generally known until Francis of Assisi, after founding the order of the Franciscans (the first order) and the order of the Poor Olives (second order), founded a third one for the numerous laymen who wished to conform themselves to the mode of life of the Franciscans as much as secular occupations would permit. When their

number increased, many of them resolved to adopt the common life, and thus the third regular order of Franciscans arose, which afterward divided itself into several congregations. (See *FRANCISCANS*, vol. vii. p. 698.) The example of the Franciscans was followed by the Dominicans, Augustines, Carmelites, Servites, and other orders, all which have connected with them both Tertiarians living in the world, and regular Tertiarians living in common.

TERTULLIAN (QUINTUS SEPTIMIUS FLORENS TERTULLIANUS), one of the early church fathers, born in Carthage about A. D. 160, died between 220 and 240. He was the son of a Roman centurion, became a lawyer, embraced Christianity and entered the Christian priesthood at a mature age, preached at Carthage and probably at Rome, and became widely known for his fondness for controversy as well as his ascetic practices. About the year 202 he joined the Montanists, attracted by their rigid morality and contempt of earthly pleasures, and their opposition to the increasing worldliness of the church, and at once became the leading defender and champion of the sect, with which he remained until his death.—The works of Tertullian are numerous and of great importance. The difference between those written before and those after he became a Montanist, seems to be more a difference of spirit than of doctrine; and his writings are classed in authority with those of the other church fathers. His *Apologeticus* has been called the first plea for religious liberty in Christian literature. Of his controversial works may be mentioned his books "Against the Gentiles," "Against the Jews," "Against Hermogenes" (showing that matter is not eternal, but created by God), "Against the Valentinians," "On the Prescription of Heretics" (asserting vehemently that no doctrine contrary to the received faith had a claim to gentle treatment or to appeal to the Scriptures, and contradicting the principles of his "Apology"), "Against Marcion," "Against Praxeas," "On the Soul," "On Baptism," "On the Flesh of Christ," and "On the Resurrection of the Body," in all of which he opposes growing errors, and seeks to show what is the true doctrine of the church. Among his practical works belong the book "On Penance;" that "On Prayer," which explains the Lord's prayer, and mentions the ceremonies proper for that practice; "On Patience," which he passionately and intemperately commends; "To the Martyrs," a pathetic appeal and encouragement; "On Theatrical Shows;" "On Idolatry," a casuistical discussion of the degree to which idol worship may be tolerated by Christians; "On the Dress of Women," and on the "Veiling of Virgins," which teach that modesty and the hiding of the features are proper for women in the house of God; and the book to his "Wife," in which he proclaims his aversion to second marriages. His specially Montanist works are the "Exhortation to Chastity" and "On Monogamy," in

which he carries to absolute prohibition the theory of the book to his "Wife," "On Chastity," which denies that those who are guilty of gross sins can be absolved; "On Repentance;" "On Fasting," explaining the obligation of the new fasts required by Montanism, and the method of keeping them; "On the Soldier's Crown," which praises a Christian soldier for refusing to wear a garland, when Christ was crowned with thorns; and "On Flight," which insists that Christians ought not to flee from persecutions. Tertullian's works are written in a rude Punic Latin interlarded with African idioms and phrases of corrupted Greek. His earlier works are said to have been written in Greek, but have come down only in Latin translations. The style of all is nervous, abrupt, confused, and vehement. The first collected edition of them is that by Beatus Rhenanus (fol., Basel, 1521). Among the numerous later editions are those by Semler (6 vols., Halle, 1770-'78), Leopold in Gersdorf's *Bibliotheca Patrum Latinorum* (vols. iv. to vii., Leipsic, 1839-'41), Migné (Paris, 1844), and Oehler (8 vols., Leipsic, 1858). Translations of several, especially of the "Apology," have been published in most of the modern European languages. The life of Tertullian has been often written—by Jerome in the early church, and in modern times by Neander (*Antignosticus*, Berlin, 1825) and Hesselberg (Dorpat, 1848). His doctrine and influence are well discussed in the special works on Montanism by Wernsdorf (1751), Münter (1829), Schwegler (1841), and Baur (1851).

TERUEL, a N. E. province of Spain, in Aragon, bounded N. by Saragossa and Huesca, E. and S. by Tarragona, Castellon de la Plana, and Valencia, and W. by Cuenca and Guadalajara; area, 2,950 sq. m.; pop. in 1857, 238,628. The Albarracin mountains traverse it in an E. and W. direction, sending off numerous spurs on both sides. Muela de San Juan, one of the principal summits of the main range, is covered with snow during the greater part of the year, and the rivers Tagus, Oabriel, Guadalaviar, and Jucar have their sources on its sides. The province is well watered by the Guadalupe and the Jiloca, affluents of the Ebro, which bounds it on the N., the Guadalaviar, and numerous smaller streams. Between the mountains there are extensive plains of great fertility, which produce grain, wine, oil, silk, hemp, flax, saffron, and fruit. Coarse woollen goods, linen, canvas, leather, paper, and earthenware are manufactured.—TERUEL (anc. *Turba*), the capital, is situated on the left bank of the Guadalaviar, 142 m. N. E. from Madrid; pop. 7,165. It stands on elevated ground, is surrounded by old walls, and entered by 9 gates surmounted by Aragonese towers. There is a bull ring outside the town capable of accommodating 9,000 spectators.

TESTAMENT, Old and New. See BIBLE.

TESTIMONY. See EVIDENCE.

TESTUDINATA, a term employed by Klein, and adopted by Agassiz, synonymous with chelonians, and embracing the reptiles known as tortoises and turtles. They are the highest of the class, approaching the lower or aquatic birds in form, mode of existence, and in some points of structure; the regions of the body are distinctly marked, and the head acquires a considerable mobility on the neck. Strans-Durckheim regards the testudinata as a distinct class, higher than, and not an order among, reptiles; a view which cannot be sustained, as both are built up in the same way as to structure of skeleton, nervous system, organs of sense, locomotion, and digestion, and have an identical mode of development; the only differences are the ordinal ones of complication of structure. Duméril and Bibron divide the order into 4 families according to the habitat, as follows: *thalassites* or marine turtles; *potamites* or river tortoises; *elodites* or marsh tortoises, with the sub-families *cryptodères* (which bend the short neck like the letter Z, and conceal the head on the median line beneath the carapace), and *pleurodères* (which curve the long neck horizontally and on the side of the body under the shell); and *chelonites* or land tortoises, the last named being the highest in rank. Agassiz ("Contributions to the Natural History of the United States of America," vol. i. part 2) adopts Oppel's subdivision of the order, making the sub-orders: I. *chelonii*, with the families: 1. *chelonoides* (marine turtles), and 2. *sphargidides* (leather or trunk turtles); and II. *amyda*, with the families: 3. *trionychides* (soft-shelled tortoises); 4. *chelyoids* (*matamoras*); 5. *hydraspidides* (like *pletemys* and other flattened species, mostly South American), united by J. E. Gray to the preceding family; 6. *chelydroides* (snapping turtles); 7. *cinosternoides* (mud turtles); 8. *emydoides* (fresh water species like the terrapins); and 9. *testudinina* (land tortoises like the great Galapagos gopher, and common European tortoises). The characters of the sub-orders with their families will be given under TORTOISE and TURTLE, which may be considered as corresponding sufficiently well to the *amyda* and *chelonii* of Oppel. The skeleton is in great part external, their bony box being covered only by comparatively thin scales or a naked skin; the most striking character is the stiff vertebral column, spreading in the shape of a carapace or shield, connected by a lateral bridge with the plastron or ventral plate, between which the organs of the trunk are enclosed, and having an anterior and a posterior opening for the protrusion of the head, limbs, and tail, which are all free; locomotion is always performed by the 4 limbs. The shield consists of a hard and dry epidermic covering, under which is a bony plate made up of the vertebrae, ribs, and sternum, overlaid and the intervals filled with the ossified skin or dermal skeleton, divided into many pieces united by

suture; in the marine turtles this dermal skeleton is imperfect (especially below), less developed in the trionyx, and least of all in the trunk turtle (*sphargis*). The epidermic plates in the tortoise-shell turtle grow only on the anterior edge, the older parts moving backward, much as in the human nail; but in the land tortoises they increase below and on all sides, in concentric rings, like the annual growths of a tree; there is every intermediate stage between these types; a moulting of the epidermis takes place in all chelonians, scale by scale. In all except the imbricated turtle the colors are situated in the lowest layers of the epidermis; in this they exist in the external dry horny layers, displaying the beautiful and permanent hues of tortoise shell; the variation of color is very great in many species; in the corium or true skin is deposited the phosphate of lime of the dermal skeleton. The skull is solid and compact, and the facial bones are immovably fixed to the cranium; the lower jaw consists of a firm bony arch; the occipital bone strikingly resembles a vertebra, the parietals principally enclose the brain, there are 2 pairs of frontals, and the nasals are almost always wanting. The cervical vertebræ are 9, if the odontoid process be considered a distinct one, and have no transverse processes; some have a concave-convex articulation, others a convex-concave, one a biconcave (toward the lower part of the series), and one a biconvex (in the middle), giving considerable freedom of motion in certain directions without the flexibility of the bird's neck. The dorsal vertebræ are 11, of which the first is movable, the rest united into a firm arch by the continuous growth of the spinous processes; the ribs extend from between the vertebræ, being strongest where the dermal skeleton is least developed, as in *trionyx*, *sphargis*, &c.; the sternum consists of 4 pairs and one odd bone, varying much in size and connection, united to the ribs by a bony bridge, the marginal plates being dermal bones; the caudal vertebræ are very movable, convex behind, concave before, and without spinous processes. The scapular and pelvic arches are withdrawn under the bony roof of the body; the bones of the shoulder are long, straight, and narrow, the scapula and acromion united at right angles, the coracoid running backward among the muscles, and the 3 united to form the glenoid cavity; the humerus is short, crooked, and turned inward; the forearm and hand have their transverse diameter vertical, the ulna overlying the radius, so that the limb may be drawn back under the carapace by the bending of all the joints in the plane of the scapula; the form of the hand varies in the different families, according as it is used for terrestrial or aquatic locomotion. The pelvic arch is formed by 8 permanently distinct bones, which meet in the cotyloid cavity; the bones of the hind legs are like those of the anterior, but the femur is straighter than the humerus; there are great differences

in the relative size of the 2 pairs of legs in the 2 sub-orders. The cervical muscles are largely developed for the purpose of darting forward and retracting the neck; the muscles of the limbs are much like those of mammals. The cerebral hemispheres are hollow and larger in proportion than in other reptiles, with a generally smooth surface; as in other reptiles the trigeminus is the largest nerve, but in these the par vagum is relatively larger than in the others; the 2 swellings of the spinal cord from which the nerves of the limbs arise are characteristically large. There is no movable external ear as in the crocodiles, but a tympanic cavity and membrane, the former divided into 2 parts by a bony partition; the eyes are larger and more movable than in the lower reptiles, similar to those of birds in the lids, nictitating membrane, osseous framework of cornea, and round pupil; a lachrymal gland is present. Hearing and vision are acute, but smell is dull, the nostrils being used chiefly for their slow respiration; they chew their food, and the tongue is broad, thick, and fleshy, with an acute sense of touch, perhaps approaching a sense of taste; the tongue is of use also in the respiratory process, as they swallow air into the lungs. The upper jaw always shuts over the lower, and both are covered with a peculiar horny sheath; the intestines, as in the higher classes, are longest in the herbivorous families, but the proportions of the different parts vary much without any special reference to the food; they are 9 times the length of the shield in the omnivorous red-bellied terrapin, and only 4½ in the carnivorous soft-shelled trionyx; the liver and gall bladder are large; spleen and pancreas always present, the former solid and generally attached to the latter, and this to the duodenum; the pancreas is lobular and irregular, and much the largest in the carnivorous feeders; digestion is performed very slowly, and hunger can be endured a long time. Respiration is effected by swallowing air, on account of the immobility of the thoracic cavity, assisted, according to Agassiz, by the diaphragm, which is well developed in the order, and by the scapular and pelvic muscles; the lungs are voluminous, most so in the land tortoises; the trionyx can remain half an hour or more under water, aëration of the blood in this and other aquatic species being doubtless partly effected, as in frogs, through the naked skin; many species have the power of emitting vocal sounds, independent of the sharp hiss which they all produce; respiration is reduced or entirely suspended in the hibernating species, according to the degree of this state. The heart is just above the liver, between its halves; the ventricle is single, divided into 2 cavities by an imperfect partition, and gives rise both to the 2 aortæ and the pulmonary artery; it beats about 10 times a minute; the lymphatic system is greatly developed, 2 hearts near the base of the tail sending the lymph over the body. The kidneys are comparatively small, flattened and

lobed, in the pelvic cavity, outside the peritoneum; the ureters short, and bladder large; the ovaries are much like those of birds, and the number of eggs matured in a year varies in different members of the order; the cloaca is very large in both sexes; all are oviparous, and the eggs are spherical, covered with a hard shell, and laid in moist or dry ground or hot sand, the number varying from 4 or 5 in the land tortoises to more than 100 in the marine turtles; the young, which appear from the egg in from 6 weeks to 4 months or more, are generally very different in form from the parents; there is a hard tubercle on the snout of the young for breaking through the shell of the egg. The growth is very slow, and they attain the period of puberty the latest of all reptiles; very tenacious of life, they can exist a long time without nourishment, and give signs of vitality, according to Redi's experiments, 28 days after decapitation, so great is the irritability of the muscles; the same experimenter ascertained that a land tortoise lived for 6 months, blindly groping about, after the brain had been entirely removed; they attain a great age, even more than a century. They are most abundant in the warm regions of the earth, and the land tortoises especially in Africa, and subsist chiefly on vegetable substances, though many aquatic species are highly carnivorous. The marine turtles are herbivorous, shy, sluggish, and inoffensive; the trionyxes active, savage biters, preying on fresh water shells and aquatic larvae; the snappers attack larger prey, and are very ferocious; the mud turtles are carnivorous, active, but not savage; the fresh water species omnivorous, timid, and inoffensive; and the land tortoises herbivorous, slow, and gentle. Genera among chelonians contain comparatively few species. Their flesh and eggs are delicious, and the shell of the hawk's-bill turtle is an important article of commerce; their flesh, blood, and bile, and the ashes of the shell, entered largely into the pharmacopœia of the ancients, and were highly prized in various diseases. According to classic mythology, the tortoise was imprisoned in its bony box for having preferred to remain at home when the animals were invited by Jupiter to celebrate his marriage with Juno; fond of and secure at home, it was condemned to carry its house with it wherever it went; the ancients accordingly made it the emblem of the domesticity and silence which they considered becoming in their wives and daughters, by whom its image in various substances was worn as an ornament; Apelles painted and Phidias carved it under the feet of the goddess Venus, by whom they represented all that was amiable, beautiful, and modest in the female sex.—Chelonians first appeared on earth in the oolitic period, according to Agassiz, when neither genuine birds nor mammals existed; the so called tortoise footprints in the new red sandstone and devonian strata were undoubtedly made by crustaceans or other articulates; according to Pictet, im-

pressions of their shields first occur in the Jura limestone and the Stonesfield oolite, and the 4 types of Duméril and Bibron together; they also are found in the tertiary and diluvial deposits. In the diluvium of the Sivalik hills of the Himalaya range have been found the remains of a gigantic chelonian (*colossochelys atlas*, Cantl. and Falc.), which must have been 18 to 20 feet in length; it would seem that its existence was known to the natives, as this figure enters largely into the old East Indian cosmogonies. In geological times chelonians existed in northern regions of Europe and Asia, now too cold for them; marine and fresh water species also are often found together, a fact explained by estuary deposits, a more uniform constitution of the early waters of the globe, and a mixture by sudden inundations and surface changes. The present geographical range of chelonians is less extensive than in the other orders of reptiles, the marine turtles having the greatest and the terrestrial species the least; the marine species are also the largest with the exception of the Galapagos tortoise. Prof. Agassiz makes 2 faunæ of marine turtles, one of the Atlantic, the other of the Pacific and Indian oceans, the same 4 genera existing in each, the only differences being specific. He makes 5 North American chelonian faunæ, each having characteristic species: 1, the north-eastern, from the 45th isotherm, going through Nova Scotia, New Brunswick, and Canada West as far as Lake Erie on the west, and south to North Carolina and Georgia; 2, the western, from western Pennsylvania to the dry plains at the foot of the E. slope of the Rocky mountains, north almost to Lake Superior, and south to Tennessee and Arkansas; 3, the southern, from the Atlantic coast of North Carolina southward to the gulf of Mexico, and west to Texas and Arkansas; 4, the Mexican; and 5, the Californian fauna. Chelonians are scarce on the western coast of North America, as on that of western Europe; there are none on the table land between the Sierra Nevada of California and the Rocky mountains, and the eastern slope of the latter to the great American desert; in the Alleghanies many species ascend to a height of several thousand feet, as the Virginia tortoise and the common snapper.

TETANUS, a spasmodic disease characterized by painful, involuntary, and protracted contraction of a greater or smaller number of the voluntary muscles. As seen in temperate climates, the disease is almost invariably consequent upon a wound or injury; but in particular localities and in hot climates, it may supervene without any lesion either external or internal. In a certain number of cases, the disease commences with chills and a feeling of depression and debility, with vertigo and sleeplessness. At first there is commonly a feeling of stiffness and uneasiness about the muscles of the neck and jaws. The patient thinks he has taken cold or has a slight rheumatic affection. He finds he is unable to separate the

jaws to any distance, and more or less gradually they close, so that he is unable to open the mouth at all. This constitutes tetanus or locked jaw, and gives rise to the common name of the disease. As the disease advances there is acute pain at the bottom of the stomach, extending through toward the back; and this pain, like the contractions of the voluntary muscles, is aggravated in paroxysms. Gradually the large muscles of the trunk and extremities become affected. In some cases all the muscles are firmly contracted, and the body remains stiff and straight; if a limb is raised, the trunk is raised with it. Ordinarily the strong extensors of the trunk and limbs are more affected than the flexor muscles, or their superior power overcomes the resistance of these latter, and during the paroxysm the body is forcibly curved backward, the patient resting upon his hands and heels only. This constitutes *opisthotonos*. Occasionally, though it must be very rarely, the body is bent forward, constituting *emprostotonos*; and still more rarely there is lateral curvature, forming *pleurosthotonos*. The muscles concerned in deglutition are early affected, so that swallowing is rendered difficult or impossible. Later in the course of the disease spasms of the muscles of the face occur. When this is the case, the brow is knit, the eyes wide open, fixed and staring, the nostrils distended, and the angles of the mouth drawn back, exposing the clenched teeth; this frightful contortion is the *risus sardonicus*. When the disease has once set in, the muscles affected are rarely at any time afterward wholly relaxed, almost always some degree of tension and spasm constantly remaining; at intervals more or less closely approximated to each other according to the severity of the disease, paroxysms occur during which the spasm is aggravated, the muscles affected becoming tense and hard as boards. During these paroxysms the patient commonly suffers from intense pain in the muscles affected, and, as was before stated, the substernal pain, dependent probably on spasm of the diaphragm, is likewise aggravated. So violent are the spasms that cases have occurred in which the teeth have been broken, bones fractured, or muscles torn across. The spasms come on even when the patient is perfectly at rest; but they are evidently excited by the slightest attempt at voluntary motion, by efforts at deglutition, or by mental emotion. The patient's mind is commonly unaffected throughout the disease; the bowels are apt to be obstinately constipated, and when evacuations are obtained they are offensive and unnatural; the breathing and pulse are quickened, and during the paroxysms the patient breaks out into a sweat. Toward the termination of the disease, the pulse is exceedingly small and frequent and the sweat cold and clammy. Death may occur either suddenly during a paroxysm or from suffocation, the muscles of respiration becoming fixed and the spasm in some instances probably affecting the glottis. In other cases death oc-

curs from exhaustion, the patient being worn out by pain, sleeplessness, and want of nourishment.—Tetanus is an exceedingly fatal disease, death taking place in the large majority of cases. Post-mortem examination throws no light on its pathology. In cases arising from wounds, the nerve leading from the wound shows evidences of inflammation, being commonly red and swollen; but with this exception no lesions have been found which are constantly connected with the disease. As was before stated, tetanus is either idiopathic or traumatic. Idiopathic tetanus, rare in temperate, is not uncommon in hot climates; but though heat acts as a predisposing cause, the exciting cause is generally exposure to damp and cold. Some other conditions beside mere temperature, however, must have an influence in the production of the disease, since it is well known that in a part of Suffolk county, Long island, it appears to be almost endemic, and wounds and injuries are exceedingly apt to be followed by its development. In traumatic tetanus, exposure to cold, particularly when the body is debilitated by the previous occurrence of warm weather, would seem to be an efficient cause of the disease. Thus the wounded in the battle of Dresden, who were exposed to cold and wet just after the battle, while the previous weather had been hot and oppressive, suffered severely from tetanus; and after the battle of Bautzen, where the wounded lay on the field exposed to cold and rain during the night, Larrey found more than 100 attacked with tetanus the next morning. It would seem that tetanus is more liable to follow punctured and lacerated than incised wounds, and that wounds of the palmar surface of the feet and hands, most abundantly supplied with nerves, are particularly dangerous; but it may follow wounds of every character; even those made by the knife of the surgeon and the stroke of a whip, the cutting of a corn and extraction of a tooth, have all been followed by this formidable and fatal disease. Cases are on record in which lying-in women have been seized by the disease; and the writer has seen an instance in which a healing ulcer, caused by a slough occurring in the course of typhoid fever, appeared to have been the cause of a fatal attack. The time which elapses between the reception of the injury and the period of invasion of the disease varies very much in different cases. Larrey states that during the campaign in Egypt it rarely appeared before the 5th or after the 15th day; yet some cases are on record in which it came on in a few hours, and others in which it was delayed for more than a month.—As we have seen, the prognosis in tetanus is generally unfavorable. When the paroxysms come on suddenly, recur at short intervals, and increase in violence, treatment is rarely of any avail; death in such cases occurs often as early as the 2d, and is rarely delayed beyond the 5th day. When the attack is less violent and the interval between the paroxysms longer, the pros-

pects of the patient are better, and if life is protracted beyond the 10th day he will frequently recover. The treatment of tetanus is an unsatisfactory subject. The severer cases die under every kind of treatment, and the milder have recovered under a variety of remedies. The inhalation of chloroform has been strongly recommended, and where it is well borne, it mitigates greatly the sufferings of the patient. Opium has been given in large and repeated doses; when recourse is had to it, it should be administered in a liquid form, or some salt of morphia should be used. A strong solution of the sulphate of morphia might be given by subcutaneous injection. Wine and distilled spirits, with or without opium, have been given in large quantities, and in many cases apparently with benefit. The bowels should be occasionally moved by active purgatives. Nux vomica and strychnine are the strictly homœopathic remedies; while conium and its alkaloid conide are the most perfectly antagonistic medicines, for they cause a rapidly increasing paralysis, first of the voluntary muscles, then of the respiratory muscles of the chest and abdomen, and finally paralysis of the spinal marrow, as Van Praag calls it.

TETRACHORD (Gr. *τετρα*, four, and *χορδή*, a string), in ancient music, a concord, consisting of 3 degrees or intervals and 4 terms or sounds, of which the highest is a perfect fourth to the lowest. Hence in modern music it is commonly called a fourth. The Greek lyre of 4 strings was frequently called a tetrachord.

TETZEL, or **TEZEL**, **JOHANN**, a Dominican monk and preacher of indulgences, born in Leipsic (not at Pirna, as is stated by some writers) between 1450 and 1460, died there in July, 1519. He studied theology and philosophy at the university of Leipsic, and in 1489 entered the order of Dominicans. He gained some celebrity as a popular preacher, and therefore was repeatedly engaged to preach indulgences which the pope had granted for raising money for religious purposes. The early Protestant biographers of Tetzel say that he sold certificates of indulgences without requiring previous confession, and indulgences for future sins; that he led a very immoral life, and was even convicted at Innsbruck of adultery; but Catholic historians have generally qualified these statements as gross exaggerations, though they admit that he often offered the indulgences in an offensive and mountebank way. In 1516 Tetzel commenced the publication of an indulgence designed to procure means for the construction of St. Peter's at Rome, receiving at the same time an appointment as inquisitor. Never before had the preaching of an indulgence produced such a commotion. He is said to have assured the people that as soon as the money resounded in the chest the sins would be forgiven, and the souls of the departed received into heaven; but Catholics, on the other hand, maintain that this is conclusively refuted by the *Instructio Summaria Sacerdotum ad Pra-*

dicandas Indulgentias, prepared by Tetzel in 1517, in which he makes the gaining of an indulgence expressly dependent upon repentance and confession. As a delegate of the highest ecclesiastical authorities, Tetzel was generally received with great pomp, but at the same time met with a powerful and rapidly increasing opposition. On Oct. 31, 1517, Luther posted the celebrated 95 theses against the abuses in preaching indulgences on the door of the church in Wittenberg. Tetzel publicly burned the theses at Jüterbogk, and in Jan. 1518, defended in a public disputation at the university of Frankfurt-on-the-Oder a number of anti-theses. The students of Wittenberg, in their turn, burned 800 copies of the antitheses of Tetzel. Tetzel replied once more, in May, 1518, by a refutation of the sermon of Luther on indulgences and grace, but seems to have had no longer any influence on public opinion. The new papal nuncio Miltitz, who hoped to gain Luther back by a spirit of conciliation, reprimanded Tetzel severely, and threatened him with the wrath of the pope. So many reverses of fortune accelerated the death of Tetzel. Among the latest biographers of Tetzel are Hoffmann, a Protestant (*Lebensbeschreibung von Tetzel*, Leipsic, 1844), and Gröne, a Roman Catholic (Paderborn, 1858).

TEUCER (Gr. *Τευκος*). I. The first king of Troy, son of the river god Scamander, by the nymph Idæa, after whom the Trojans are sometimes called Teucrions. II. A Grecian hero in the war against Troy, the son of Telamon, king of Salamis, and Hesione of Crete, and a stepbrother of Ajax. He was the best archer among the Greeks; but on his return from Troy his father refused to receive him in Salamis because he had not avenged the death of Ajax nor brought back his body. He therefore settled in the island of Cyprus, and founded there the city of Salamis.

TEUTONIO KNIGHTS, **ORDER** of, a powerful military order which originated during the crusades. During the siege of Acre in 1189 the sufferings of the soldiers were so great, that a charitable society for the care of the sick and wounded was instituted by citizens of Bremen and Lübeck. This was raised by Frederic Barbarossa to an order of knighthood, the rule of which was similar to that of the templars. None could be members but men of noble rank. The dress was black with a white mantle upon which was a black cross with a silver edging. The order had an elective grand master, who first dwelt at Jerusalem, then when Palestine fell into the hands of the Turks at Venice, and from 1297 at Marburg. They were dedicated to the service of the Virgin Mary, and the knights also called themselves "Brethren of the German House of our Lady of Jerusalem." Called to the work of evangelizing the heathen Prussians by force of arms, the order laid early in the 13th century the foundation of its future greatness by the acquisition of Culm. From this point they extended their conquests over

the duchies of Prussia, Courland, and Livonia, exterminating the pagan inhabitants with fire and sword. In 1309 the grand master fixed his seat at Marienburg. Possessing the richest and most commercial provinces of the north, the order became exceedingly powerful; and at the beginning of the 15th century, when it had reached its greatest prosperity, its territory extended from the Oder to the gulf of Finland, and its yearly revenue was estimated at 800,000 marks. Nobles from all parts of Europe flocked to its banner, and Henry IV. of England, when earl of Derby, fought under it in 1390. Internal dissensions, luxury, and unjust and oppressive acts threatened its decline from this period, and a conflict with the Polish kings hastened it. In the battle of Gr nwald or Tannenberg in 1410 they were totally defeated by Ladislas Jagiello; and after a subsequent long war with Casimir IV., West Prussia was given up to Poland, and for East Prussia they were compelled to do homage. A war to regain their independence deprived them of East Prussia, which in 1525 was presented by Sigismund I. of Poland to the grand master, the margrave Albert of Brandenburg, as a hereditary duchy. The order was now reduced to a mere shadow of its former greatness. In 1527 the grand master fixed his seat at Mergentheim in Swabia, became a spiritual prince of the German empire, and had under him 11 provinces divided into commanderies, comprising 850 square miles with 88,000 inhabitants. In 1805 the peace of Presburg gave to the emperor of Austria the rights, revenues, and possessions of grand master of the Teutonic order; but in the campaign of 1809 Napoleon while at Ratisbon abolished the order on April 24, its widely scattered territory falling to the princes in whose dominions it was.

TEUTONS (Lat. *Teutones* or *Teutoni*), a powerful people of ancient Germany, who probably dwelt on the southern shores of the Baltic, in the vicinity of the Cimbric, together with whom they invaded the dominions of the Roman republic at the close of the 2d century B. C., when they were annihilated by Marius. (See CIMBRI.) The name Teutons is also applied to the ancient Germans in general, whose language, the parent of the modern German, the Dutch and kindred dialects, and the Anglo-Saxon, is therefore called the Teutonic (Ger. *Deutsch* or *Deutsch*). The latter term is also used (adjectively) of the Germanic race in a limited sense, embracing the Germans, Dutch, Frisians, Flemings, Swiss, and the descendants of the Anglo-Saxons; and in a wider sense including also the Swedes, Norwegians, Danes, and Icelanders. Accounts of all the Teutonic nations and languages are given in this work under their respective heads.

TEXAS, one of the S. W. states of the American Union, the 13th admitted under the federal constitution, situated between lat. 25  50' and 36  30' N. and long. 98  30' and 107  W.; extreme length from S. E. to N. W.,

more than 800 m.; greatest breadth from E. to W., about 750 m.; area estimated at 287,504 sq. m. or 152,002,560 acres. It is the largest state in the Union, and has a territory nearly 6 times as great as that of Pennsylvania. It is bounded N. by New Mexico, the Indian territory, from which it is separated by the Red river, and Arkansas; E. by Arkansas and Louisiana, from the latter of which it is separated in part by the Sabine; S. E. by the gulf of Mexico; and S. W. and W. by Mexico and New Mexico. It is divided into 154 counties, viz.: Anderson, Angelica, Archer, Attacosta, Austin, Bandera, Bastrop, Baylor, Bee, Bell, Bexar, Blanco, Bosque, Bowie, Brazoria, Brazos, Brown, Buchanan, Burleson, Burnett, Calahan, Caldwell, Calhoun, Cameron, Cass, Chambers, Cherokee, Clay, Coleman, Collin, Colorado, Comal, Comanche, Conchos, Cook, Coryell, Culloch, Dallas, Dawson, Denton, De Witt, Dimmitt, Duval, Eastland, Edwards, El Paso, Encinal, Erath, Falls, Fannin, Fayette, Fort Bend, Freestone, Frio, Galveston, Gillespie, Goliad, Gonzales, Grayson, Grimes, Guadalupe, Hamilton, Hardeman, Hardin, Harris, Harrison, Haskell, Hays, Henderson, Hidalgo, Hill, Hopkins, Houston, Hunt, Jack, Jackson, Jasper, Jefferson, Johnson, Jones, Karnes, Kauffman, Kemble, Kerr, Kinney, Knox, Lamar, Lampasas, La Salle, Lavaca, Leon, Liberty, Limestone, Liveoak, Llano, McLennan, McMullen, Madison, Marion, Mason, Matagorda, Maverick, Medina, Menard, Milam, Montague, Montgomery, Nacogdoches, Navarro, Newton, Nueces, Orange, Palo Pinto, Pannola, Parker, Polk, Presidio, Red River, Refugio, Robertson, Runnels, Rusk, Sabine, San Augustine, San Patricio, San Saba, Shackelford, Shelby, Smith, Starr, Tarrant, Taylor, Throckmorton, Titus, Travis, Trinity, Tyler, Upshur, Uvalde, Van Zandt, Victoria, Walker, Washington, Webb, Wharton, Wichita, Wilbarger, Williamson, Wise, Wood, Young, Zapata, and Zavalla. There are no large cities in the state; the principal towns are: Austin, the capital; San Antonio, the largest town of western Texas; Galveston, the largest commercial port of the state; New Braunfels, the largest of the German settlements; Houston, Marshall, Victoria, Fredericksburg, Corpus Christi, Indianola, Nacogdoches, Castroville, Palestine, Eagle Pass, Lavaca, Richmond, and Rush. The following table exhibits the population of the state at different periods, estimated except for the U. S. census years 1850 and 1860:

Date.	Whites.	Indians and Mex.	Free colored.	Slaves.	Total.	Percentage of increase.
1806....	7,000	..
1834....	21,000	300.00
1836....	80,000	17,670	5,000	..	52,670	150.00
1845....	150,000	185.00
1850....	154,481	..	397	53,161	212,599	41.70
1860....	180,682	601,089	182.71

Of the white population in 1850, 84,863 were males and 69,287 females; of the free colored,

211 males and 186 females; and of the slaves, 28,700 males and 29,461 females. The density of population the same year was .89 to the square mile. The whites and free colored occupied 27,988 dwellings, and constituted 28,877 families. The number of deaf and dumb was 59, of blind 73, of insane 87, and of idiots 104. Births (of white and free colored), 4,765; marriages, 2,282; deaths, 2,219; total deaths (including slaves), 3,096. Ages of the total population: under 1 year, 6,194; 1 and under 5 years, 30,594; 5 and under 10, 82,549; 10 and under 15, 28,089; 15 and under 20, 22,568; 20 and under 30, 40,107; 30 and under 40, 26,096; 40 and under 50, 14,969; 50 and under 60, 7,819; 60 and under 70, 2,791; 70 and under 80, 793; 80 and under 90, 221; 90 and under 100, 49; over 100, 89; and 214 unknown. Of the white and free colored population, 49,160 were born in the state, and 87,898 in other states of the Union, making 137,058 of American birth, while 17,378 were born in foreign countries, of whom were from the United Kingdom 2,688 (Ireland 1,408), Germany 8,277, Norway 105, Switzerland 184, France 647, British America 187, and Mexico 4,459. The occupations of 42,856 free males over 15 years of age in 1850 were as follows: commerce, trade, manufactures, mechanic arts, and mining, 7,327; agriculture, 25,299; labor not agricultural, 6,194; army, 584; sea and river navigation, 321; law, medicine, and divinity, 1,368; other pursuits requiring education, 996; government civil service, 677; other occupations, 90. The number of slaveholders in 1850 was 7,747, viz.: holders of 1 slave, 1,935; of 1 and under 5 slaves, 2,640; 5 and under 10, 1,585; 10 and under 20, 1,121; 20 and under 50, 874; 50 and under 100, 82; 100 and under 200, 9; 200 and under 300, 1. The federal representative population of Texas in 1860 was 529,972, entitling the state to 4 representatives in the next congress.—The coast of Texas, like that of North Carolina, is bordered with a chain of low sand islands, formed from the deposits of the Mississippi and other rivers, between which and the mainland lie a series of bays, sounds, and lagoons; the most important of these, commencing at the N. E., are Galveston, Matagorda, Espiritu Santo, Aransas, and Corpus Christi bays, and the Laguna del Madre. Galveston bay is the largest, and has the best entrance, its inlet having 12 feet of water, while in good anchorage just outside there is 24 feet; it extends inland from the gulf of Mexico 35 m. Matagorda bay, 60 m. long by 6 to 10 wide, and Laguna del Madre, 90 m. long by 3 to 6 wide, are properly sounds, and run parallel with the shore. The entrance of Matagorda bay, which is rapidly filling up, has only 7 feet of water; and San Luis inlet, the entrance to West bay, a sound connecting with Galveston bay, has but 6 feet. Aransas bay is 25 m. long from N. E. to S. W. and about 12 m. wide, and Copano bay, a sound opening into it, is 20 m. long by

8 wide; Corpus Christi bay is 40 m. long by 20 wide, and Espiritu Santo 20 by 10; the entrance to all these is much obstructed by the bars at the inlets. The state is generally well watered. The Rio Grande, whose sources are far up in the Rocky mountains, on the confines of New Mexico and Colorado territories, forms its S. W. boundary; and proceeding northward along the coast, we find the Nueces, San Antonio, Guadalupe, Colorado, Brazos, San Jacinto, Trinity, Neches, and Sabine, the last forming the boundary between Texas and Louisiana. The Red river is the boundary between Texas and the Indian territory through the entire extent to which they are contentious; and the Canadian, a branch of the Arkansas, crosses the northern portion. The Rio Pecos, a large affluent of the Rio Grande, drains the table lands of western Texas; and the numerous tributaries of the rivers we have named, some of which are themselves considerable streams, give all of the state, except the Llano Estacado, a sufficiency of running water. The Sabine is navigable for 150 m.; the Trinity for 350 m. or more in the season of high water; the San Jacinto, 50; the Brazos, 300; the Nueces, 100; the Rio Grande, 400; and the Red river for nearly its whole course on the N. boundary of the state, though obstructed somewhat by shifting sands for a part of the distance. The only lake of importance in the state is the Sabine, which is rather a bayou, formed by the expansion of the Sabine river. In the south, occupying a part of Nueces and Cameron counties, is the bed of an extensive salt lagoon, now dry, connected with the Laguna del Madre, where considerable quantities of salt lie on the ground.—There are no mountains of great height in Texas. The S. and S. E. portion of the state along the coast is level and of very little elevation; the middle belt is undulating; while the N. and N. W. is mostly an elevated table land, descending gradually from the snow-capped Sierra Madre in Colorado and New Mexico. From this table land, which comprises a small portion of the great American desert, and about three fourths of the Llano Estacado or Staked Plain,* and varies in altitude from 2,500 to 3,500 feet above the sea, ridges of low, broken mountain chains stretch southward, taking the names of the Organ, Waco, and Guadalupe mountains. The last named divide in the Presidio district into two ranges, one following the course of the Rio Grande, the other that of the Rio Pecos, while between them extends a plateau about

* The Llano Estacado is an elevated plain lying between the Rio Pecos in New Mexico and the head waters of the Brazos, Red river, and Big Wichita in Texas. It is from 3,000 to 4,000 feet above the sea level, and has no trees or shrubs except along the immediate margins of the streams, and never extending 100 yards from them. During the rains a scanty herbage springs up, but soon becomes dry and affords little nutriment. It proves an effective barrier to the progress of the buffalo, which would otherwise descend in vast herds upon the lower and more fertile plains of western Texas. The government in 1855-'6 made some experiments in sinking artesian wells along the plain, with a view to opening a shorter route to the S. W.

2,500 feet above the level of the Rio Grande. The highest summits of these mountains do not rise above 3,000 feet. The Waco and Organ mountains are parallel or nearly parallel with these, and lie between the Rio Pecos and the Colorado. East of the latter river is a lower range, running from N. to S., called the Colorado mountains; and between these and the Brazos are a succession of chains of hills, with an occasional summit of somewhat greater elevation, of which the principal are Caddo and Comanche peaks, Pilot Knob, and Santa Anna mountain. Between the upper waters of the Colorado and Brazos is a large tract of timbered land known as the "mezquite timber," and between the upper Brazos and Trinity a long tract from 5 to 80 m. in width, extending from Caddo peak in Johnson co. to the Canadian river in the Indian territory, and called the Cross Timbers. In the central belt the river bottoms are a rich alluvium from 8 to 20 m. in width, and usually covered with heavy timber, while the prairies extend back from the river basin. The elevated plains of the N. W. have no timber except where a stream forces its way to the surface toward their lower or S. border, and very little herbage except after the rains, when for a brief season a short stunted grass springs up, but soon dries up and affords little pasturage.—Texas, like the states along the Atlantic, presents geological formations of increasing age on passing from the coast to the interior. The country in this direction becomes successively higher, and ranges of hills are passed over, the course of which is in general parallel with the coast line. The general direction of the streams is across these ranges toward the gulf of Mexico. The counties along and near the gulf are formed of alluvial beds of sand and gravel, and on the borders of Louisiana this formation extends as far into the interior as the 31st parallel of N. latitude. The margin of the outcrop of the tertiary strata is marked by hills and rolling lands, which extend from the N. E. toward the S. W., through Jasper, Tyler, Polk, Montgomery, Austin, and Colorado cos. Near the coast at Corpus Christi, the tertiary beds were met with very near the surface in the artesian borings. There is little of geological interest or importance in the sandy district, except in Hardin co., where Dr. Shumard, the state geologist, reports the occurrence of petroleum upon the surface of some remarkable acid springs adjacent to Sour lake. For some distance around these springs the earth is said to be so charged with bitumen as to be employed for purposes of illumination, and to some extent as a fuel. The tertiary belt extends nearly to the N. E. corner of the state, and occupies many of the middle counties in its range S. W. The several groups of the formation abound in fossils of great variety, and afford fertilizing marls and gypsums, and also extensive beds of brown coal or lignite. Some of the last, examined by Dr. Shumard in Rusk co., are from 6 inches to

8 feet thick, and are associated with bituminous shales, fire and potters' clay, sandstones, impure limestones, and iron ore. The lignite sometimes preserves the woody fibre, and sometimes it is of a dull shining black, very compact in texture, with no trace of organic structure. It is likely to be of some value throughout the middle portion of the state as a fuel, and perhaps for the manufacture of illuminating gas. The same formation also contains large bodies of hematite; and in Cass co., on the borders of Louisiana, this ore has been used for some years to supply a blast furnace, which is the only one in the state. Similar ores are said to be very abundant in Rusk, Cherokee, and Nacogdoches cos. Beyond the tertiary region is a wide belt occupied by the cretaceous formations, consisting of beds of limestone, sandstone, clays, and marl. Most of the strata abound in the fossils common to this group, and the prevalence of calcareous matters insures great fertility to the soils of this region and to those of the valleys in the tertiary district below. The western margin of the formation is as far back as Grayson co. on the Red river. To the S. it is met with as far W. as the counties of Johnson, Bosque, Coryell, Burnet, &c. Beyond this region toward the N. W. the coal measures are met with. Young and Buchanan cos. lie in their range, and as many as 4 distinct coal seams have here been recognized, varying from 6 inches to 5 feet, and presenting an aggregate thickness of 8 or 9 feet. The coal beds rest on fire clay, and have their usual accompaniments of shales, sandstones, conglomerates, limestones, argillaceous iron ores, &c. The shales contain a large amount of gypsum, some of it in large and beautiful crystals of selenite. The coal formation is supposed to extend northward into Baylor, Archer, and Clay cos., and southward in the direction of San Saba co., and thence probably to the extreme western part of the state, comprising an area of about 5,000 sq. m. The coal is bituminous, and resembles in quality that of Missouri, Kansas, and Iowa. The formations in the N. W. counties are palaeozoic strata abounding in beds of gypsum. In Baylor and Knox cos., between the Brazos river and the Big Wichita, are hills nearly 700 feet high composed almost entirely of this material. It is usually pure white, more or less granular, and is also sometimes fibrous, sometimes a compact alabaster, and sometimes crystallized as selenite. The azoic rocks appear to be met with in but few localities in the state. A rather coarse red granite is described as occupying a considerable portion of Burnet co. in the region of the cretaceous formation, and a beautiful variegated limestone of fine texture, which forms a handsome marble, and is perhaps a metamorphic rock, is also found in the same vicinity. It is recently reported that saltpetre is found in considerable quantity in the limestone caves of this county, and collected for the manufacture of gunpowder. In Llano

co., adjoining, metallic ores are met with, as the molybdate of lead, which also seems to indicate metamorphic action. Specimens of lead and copper ores have been brought from the western and northern cos., but no evidence is afforded of the existence of valuable deposits. The lead ores are found to be more or less argentiferous.—The soil of Texas is characterized in general by great fertility. The river bottoms are unsurpassed in this respect by those of any state of the Union. There are 3 or 4 varieties of soil, each well adapted to certain crops. The stiff black soil of the river bottoms is fittest for sugar and cotton, though the latter grows well on the prairies and uplands; the finer black or chocolate-colored soil of the prairie lands yields abundant crops of corn and the cereals, and the lighter copper-colored soil of the uplands is admirable for the grasses and fruits; while the fine silt of the islands produces the best sea island cotton known. The soil of the desert tracts of the N. W. is sandy and charged with carbonate of soda and other alkalies; but even this, wherever it can be irrigated, produces moderately grass and herbage.—The climate of the state is remarkably salubrious, and though sufficiently warm for the production of most of the semi-tropical and some of the tropical fruits, it is less enervating and more free from malarious diseases than that of any other of the gulf states. This is due mainly to two causes: the moist and warm S. E. or S. wind which prevails along the coast and blows far inland, warmed though not heated by the waters of the Gulf stream, which are divided at Cape San Antonio by the colder current that elsewhere underlies them, and which gives to the nights a delicious and healthful coolness, and tempers the heat of the day; and the northers, cool, dry winds, which sweep over the Sierra Madre, leaving all their moisture on its N. side, but producing a decided reduction of temperature, and a sensation of cold, from the evaporation of perspiration, much below that indicated by the thermometer. The northers occur from October to May at intervals of about a week, diminishing in intensity and duration in April and May; in western Texas they rarely last more than 3 days, while at Vera Cruz they often continue 20. They produce a smooth sea on the coast of eastern Texas, blowing directly seaward; but in western Texas, from the southward trend of the coast, they blow parallel to it, and produce a sea which no vessel can ride out at anchor. They are experienced, with different degrees of intensity, over nearly the whole state; but the tract E. of the 95th meridian to its intersection with the Trinity, and thence S. E. to the mouth of the Sabine, and that N. W. from the Pecos, may perhaps be excepted. No cases of phthisis originate within the bounds of the northers, but nervous, rheumatic, and gouty persons suffer severely during their prevalence. The norther is in some respects unpleasant, but it is said to make the climate much more healthy, and the air more pure.

With reference to the fall of rain, the state may be divided into 3 regions. The belt of abundant rains lies between the Sabine and the mouth of the Brazos; the region of moderate rains between that river and Matagorda bay; and the dry region between Matagorda bay and the Rio Grande. In this dry region not only do the northers have a greater range and more effectually absorb moisture, but the S. E. wind, or rather here the S. S. E. wind, is drier, from traversing more land before it reaches this portion of Texas. Though situated so near the West Indies, where tornadoes and hurricanes are so common, Texas is never visited by them. Hurricanes never pass the boundaries of the Gulf stream, which off Galveston is 20 m. from land. In 1858 the fall of rain at the Texas military institute, in Fayette co., was 37.74 inches; in 1859, 30.36. In 1858, at a point 15 m. E. of Austin, it was 82.78 inches. The months of greatest rain in Fayette co. were June, January, May, and December; near Austin, March, May, September, and October. The highest mean of temperature for a month in both places was in August, 81.29° and 81.10° respectively; and the lowest was in February in Fayette co., 51.04°, and in November near Austin, 49.06°. The annual mean was 66.16° in the former, and 65.42° in the latter. In 1859, in Fayette co., the highest mean was in August, 84.90°, and the lowest in December, 43°; the annual mean was 68.04°, and of the wet bulb 68.63°. The week from Dec. 2 to 8, 1859, was the coldest ever known in Texas; the average temperature of the week was 29°. Corn planting usually commences about the middle of February, and grain is harvested in the latter part of May, and Indian corn in July. Cotton picking commences about July 10, and continues to Dec. 1. The months of July, August, and September are usually very dry; often not an inch of rain falls in the 3 months.—The vegetable productions of Texas are more varied than those of any other state of the Union, the result of the great variety of temperature and soil included in it. The forest trees of the S. and S. E. are the live oak and other species of oak, the cedar, pine, palmetto, ash, walnut, hickory, pecan, mulberry, cypress, elm, sycamore, cottonwood, and Osage orange, which grows to great size. Further N., in that singular forest wall already mentioned, the Cross Timbers, which separate the dry and barren prairies of the N. W. from the fertile plains of the E., the post oak and blackjack are the principal trees, and stand so far apart as to permit wagons to pass between them in any direction. West of this, and occupying the greater part of 6 counties, is a vast mezquite forest. The mezquite is one of the indigenous trees of Texas, of the acacia tribe. It is seldom more than 6 inches in diameter, and from 20 to 30 feet in height. Its fruit is a smooth flat pod containing 20 seeds. From its bark exudes a gum resembling gum arabic. (See GUM, vol. viii. p. 569.) The tea tree, and the nopal, on which the cochineal

insect feeds, are also natives of Texas; the agave and numerous species of cacti are abundant W. of the Nueces. The fruit trees are numerous. The peach, of superior size and flavor, the nectarine, the quince, fig, plum, orange, melon, lime, mulberry, and crab apple are found in most parts of the state; and the vine yields luscious grapes, and some attention is given to the manufacture of wine. Many kinds of berries also are found in the river basins and forests. The vanilla and cayenne pepper are grown in large quantities. The flowers of Texas are of great beauty and grow in wonderful profusion. Mimosas, wax plants, cardinal flowers, trumpet flowers, lilies of numberless varieties, geraniums, asters, dahlias, and many other flowers cultivated at the north, here grow wild. The upland variety of cotton matures and yields abundantly in all parts of the state below lat. 31° N., and the sea island yields as fine a quality and larger crops than in South Carolina and Georgia, on the islands of the coast. In Texas the cotton crop, on account of the temperate character of the climate, can be cultivated to great advantage by small farmers who perform their own labor, and in western Texas (that portion of the state W. of the Trinity) large quantities are thus produced without slave labor. Sugar is made from the sugar cane chiefly in the vicinity of the Brazos river, of quality fully equal to the best Louisiana, and also from the sorghum. Indian corn is cultivated in every settled county in the state. Wheat is raised in all the interior, northern, and western counties, and yields an average of over 15 bushels to the acre. In 1858 there were 682,225 acres planted with cotton, about 225,000 acres with wheat, 16,000 either with sugar cane or sorghum, and about 1,250,000 with Indian corn. Hay is also a considerable crop; and the grasses of the state suitable for grazing or curing are numerous and of superior quality.—The wild animals of Texas are the buffalo, which still roams in considerable numbers in the N. W.; the wild horse, or mustang, of which immense herds are found on the western prairie lands; deer, pumas, jaguars, ocelots, wild cats, black bears, wolves, foxes, some peccaries, raccoons, opossums, rabbits, hares, squirrels of several species, prairie dogs, and in the mountains of the N. W. the antelope, the bighorn, and the moose. Of birds there is the greatest possible variety, including the prairie hen and other grouse, the wild goose, the wild turkey, numerous species of the duck tribe, woodcock, pigeons, turtle doves, snipe, plover, and rice birds; cranes, swans, pelicans, kingfishers, and water turkeys; the bald-headed and Mexican eagles, vultures, hawks, owls, and other rapacious birds; the blackbird, starling, blue jay, parakeet, oriole, cardinal, mocking bird, whippoorwill, woodpecker, redstart, martin, robin, swallow, and wren. There are many varieties of fish peculiar to the Texan coast and rivers, beside the species common to the gulf states. The most numerous are the red

fish, a delicious fish often weighing 50 lbs.; the yellow, blue, and white codfish; sheepshead, mullet, flounders, perch, pike, suckers, and sea trout are also abundant. The crawfish, crabs, oysters, clams, mussels, shrimps, and hard and soft shelled turtles are found all along the coasts. Great attention is paid to the raising of horses, cattle, sheep, and swine, and the camel has been introduced with some success.—Among the objects of interest to the tourist are the pass of the Guadalupe mountains in the N. W. part of the state, where the traveller finds himself wandering for hours in an apparently interminable labyrinth of mountain spurs and deep gorges, with lofty walls of terraced limestone almost shutting out his view of the sky, and dark, precipitous ravines, whose bottom is concealed by the shadows of the walls which bound it. The Castle mountain pass and the Waco mountain pass are hardly inferior to this in grandeur. In the N. of Texas the Red river cuts its way through solid rock in a *canyon* or gorge 800 feet in depth. On one of the branches of the Colorado river there is a fall of 120 feet perpendicular, the sheet of water being 100 feet in width. Numerous fossils of gigantic extinct animals have been found in different parts of the state, some of them of larger size than have been discovered elsewhere. In Houston co. there are numerous silicified trees, most of them nearly perpendicular or inclining to the N., but some lying upon the ground.—In 1850 Texas had 12,198 farms, comprising 648,976 acres of improved and 10,852,363 acres of unimproved lands, the whole value of which was estimated at \$16,550,008. The value of farming implements and machinery was \$2,151,704. In 1858 the farming lands under cultivation amounted to 47,987,537 acres, valued at \$78,677,816. The live stock in 1850 consisted of 76,760 horses, 12,463 asses and mules, 217,811 milch cows, 51,285 working oxen, 661,018 other cattle, 100,530 sheep, and 692,022 swine; the value of live stock was \$10,412,927, and of animals slaughtered \$1,116,137. The products of animals were: 2,844,900 lbs. of butter, 95,299 of cheese, and 181,917 of wool. The crops of 1849 were: wheat, 41,729 bushels; rye, 3,108; oats, 199,017; Indian corn, 6,028,876; potatoes, 1,426,803; barley, 4,706; hay, 8,354 tons; peas and beans, 179,350 bushels; beeswax and honey, 380,825 lbs.; flax, 1,048 lbs.; cane sugar, 7,361 hhd.; molasses, 441,918 galls.; cotton, 58,072 bales; rice, 82,203 lbs.; tobacco, 66,897 lbs. Value of produce of market gardens, \$12,854; of orchard products, \$12,505. In 1858 the number of horses was 238,208, valued at \$11,588,247; of cattle, 2,220,433, valued at \$13,259,537. In 1860 the number of sheep, estimated from the returns of over 100 counties, was over 850,000. The cotton exported directly to foreign ports in the year ending July 1, 1860, was 125,641 bales, valued at \$5,744,981, and the whole crop was estimated at 400,000 bales. The wheat crop of 1859 was estimated at 3,750,000 bushels; the

corn crop was about 25,000,000 bushels; the sugar crop was not estimated. The statistics of the manufactures of the state in 1850 were: value of home-made manufactures, \$266,984; manufacturing establishments, 309; capital, \$589,290; raw material used, \$394,642; hands employed, 1,042 male and 24 female; annual wages, \$322,368; annual product, \$1,165,588. Among the manufactures noted are a woollen mill, employing \$8,000 capital, using 30,000 lbs. of wool valued at \$10,000, and producing \$15,000 worth of goods; 2 iron foundries, employing \$16,000 capital; and 2 salt factories, with \$3,475 capital.—The state, in reference to its inhabitants as well as its pursuits, has two great divisions. Eastern Texas, including that portion of the state lying E. of the Trinity river, is inhabited principally by emigrants from the southern states; the landholders have mostly large plantations, hold the greater part of the slaves of the state, and cultivate by slave labor cotton, rice, sugar, wheat, and Indian corn. Western Texas, lying W. of the Trinity, is occupied mostly by emigrants from Germany, France, and other European countries, and the northern states; the farms are smaller, and cotton, sorghum, sugar and molasses, wheat, Indian corn, &c., are the principal crops, which are almost entirely cultivated by the farmers and their families, very little slave labor being employed.—The state has great facilities for both internal and foreign commerce. Her large rivers, though somewhat obstructed by sand bars, are yet navigable far into the interior; and the railroad lines in operation and in course of construction will greatly increase the facilities for bringing products to market. The direct exports from Texan ports to foreign countries in the year ending July 1, 1860, were \$6,784,984, of which \$5,839,757 worth was cotton. The direct imports for the same year were \$2,436,408. The value of imports from Mexico in 1859, for 11 months, was \$3,865,812. The enrolled and licensed tonnage of the state the same year was 7,668 tons, of which 1,006 tons were built that year. The arrivals of American and foreign vessels at the several ports of entry from foreign countries in 1859 were 76, tonnage 32,812, and the clearances for foreign countries were 108, tonnage 48,763. The internal and coasting commerce very greatly surpasses this, and the great bulk of the exports from the state are sent to New Orleans and New York, to both which ports large sea-going steamers usually ply weekly or oftener. There is but one canal in Texas, extending from West bay to the Brazos river; but there have been improvements of the rivers and harbors completed at a cost of nearly \$370,000. On Jan. 1, 1861, there were 2,667 m. of railroad projected and in progress in the state, of which 294.50 were completed, at a cost of \$9,200,000. Since that time several roads have been completed or extended. The amount in operation in the autumn of 1861 was nearly or quite 450 m. The Buffalo Bayou, Brazos, and Colo-

rado road extends from Harrisburg (which is connected with Galveston by steamer) to Columbus, a distance of 175 m.; the Houston Tap and Brazoria road, from Houston to Columbus on the Brazos, 50 m., and perhaps to Wharton on the Colorado, a further distance of about 40 m.; the Houston and Texas central, from Houston to Navasota, and probably to Booneville, 70 or 100 m.; the Washington co. road, from Hempstead to Brenham, 25 m.; the Texas and New Orleans road, from Orange on the Sabine river to Houston, 106 m.; and there is a short line from Shreveport, La. to Marshall, Texas, intended as the commencement of the southern Pacific road.—Texas has an institution for the deaf and dumb at Austin, founded in 1857, and endowed with 100,000 acres of state land; the number of pupils in 1860 was 30, and the current expenses \$9,000 per annum. There is an institute for the blind in the same city, which was incorporated in 1856, and which is also endowed with 100,000 acres of land; in 1859 it had 10 pupils, and the current expenses were \$6,500 per annum. Near Austin there is a lunatic asylum in course of erection, intended to accommodate when completed 250 patients. An appropriation of 100,000 acres of land has also been made for an orphan asylum. The state penitentiary is at Huntsville, Walker co. It is on the silent or Auburn plan, and the labor of the prisoners is let to contractors. In Sept. 1860, the number of prisoners was 200, of whom 160 were employed in the prison factory, manufacturing osanaburgs and coarse woollen goods: 8 in the cabinet and clothing shops; and 32 were sick, invalids, or in the floating force. The cost of raw material in the factory was \$76,187, and the value of the manufactured goods \$124,598.—The school fund of the state on Sept. 1, 1860, amounted to \$2,531,520.64, and the amount distributed to counties was \$112,595.81. Beside this, each county has 17,713 acres of land set apart for school purposes, and from the proceeds of this may materially increase the annual appropriation to its schools. The school fund consists of the sum of \$2,000,000 of the 5 per cent. U. S. bonds set apart for the purpose, to which is added annually $\frac{1}{10}$ of the state tax. The number of children of school age (6 to 18) in 1860 was 104,447, and the amount distributed \$1 to each. There is also a university fund, which in 1860 amounted to \$111,000, the interest of which is at present accumulating. There are numerous academies and female seminaries in the state, and 3 colleges, viz.: Aranama college (Presbyterian), at Goliad in Goliad co., founded in 1852, and which in 1860 had 3 professors, 75 students, and 1,800 volumes in its library; Austin college (also Presbyterian), at Huntsville, Walker co., which in 1858 had 5 professors and over 100 students, exclusive of those in the law department; and Baylor university, at Independence, Washington co., founded in 1845, and having 5 professors and about 150 students in 1858.

There is also a military institute of considerable reputation at Rutersville, Fayette co., established in 1856. The total number of churches reported in 1850 was 828, of which 70 were Baptist, 5 Christian, 5 Episcopal, 7 Free, 178 Methodist, 47 Presbyterian, 18 Roman Catholic, 2 Union, and 6 of minor sects. The total value of church property in that year was \$206,930, and the whole number of sittings was 64,156. In 1850 there were 34 newspapers published in Texas, printing annually 1,296,924 copies; of these 5 were tri-weekly and 29 weekly. In 1860 there were 34 newspapers published in the state, of which 3 were daily and weekly, 1 tri-weekly and weekly, 79 weekly, and 1 monthly.—The constitution, adopted in 1845, has the following among other provisions: Every free male person (Indians, Africans, and descendants of Africans excepted), 21 years of age, who is a citizen of the United States, or who was at the adoption of the constitution a citizen of Texas, and has resided in the state one year, and in the district, county, city, or town where he proposes to vote 6 months, is a qualified elector. Representatives must have been resident citizens for 2 years, and have resided in the district they represent one year prior to their election, and must be at least 21 years of age. Senators must have been resident citizens for 3 years, must have resided in the district they represent one year, and have attained the age of 30 years. The members of the house are elected for 2 years, and must not be fewer than 45 nor more than 90; of the senate, elected for 4 years, not fewer than 19 nor more than 33. The present numbers are 66 and 21. Clergymen are not eligible to the legislature nor to state offices, nor persons holding lucrative office under the U. S. government, nor collectors of taxes until they have obtained a discharge for the amount of their collections. The sessions of the legislature are biennial. The judiciary of the state comprises a supreme court, having only appellate jurisdiction, consisting of one chief justice and two associates, each having a salary of \$3,000; and 20 district courts, each presided over by a single judge residing in his own district, having original jurisdiction, and receiving a salary of \$2,250. Both the supreme and district judges are elected by the legislature on the nomination of the governor, for the term of 6 years. The governor is elected by the people for 2 years, but cannot hold the office more than 4 years in any period of 6 years; his salary is \$3,000 and a furnished house. The secretary of state is appointed by the governor for 2 years; the attorney-general, treasurer, comptroller, and commissioners of land office and claims are elected by the people biennially. The state engineer is elected by a joint vote of the two branches of the legislature; his salary is \$3,000, and that of the other state officers from \$1,800 to \$2,000. The legislature is prohibited from granting either lotteries or divorces. No individual may issue bills, checks, promissory notes, or other paper to cir-

culate as money; and no corporate body is to be created, renewed, or extended, with banking or discounting privileges. The state cannot be part owner of the stock or property belonging to any corporation. The provisions of the constitution relating to slaves prohibit their being brought into the state as merchandise, direct that they shall have jury trial in all cases above the grade of petit larceny, and that personal injuries to or maiming of a slave, or depriving him of life, shall be punished in the same way and to the same extent as if white persons, except in cases of insurrection of such slave; they also authorize the legislature to pass laws protecting the slave, and punishing the owner who maltreats him by taking him away and selling him for the owner's benefit. The state was in 1860 entirely free from debt. In 1851 it received the \$10,000,000 U. S. bonds to be paid by the U. S. government in consideration of her cession of territory and reduction of boundaries; and from the income and part of the principal of this, after settling her indebtedness, with a small tax ($\frac{1}{4}$ of 1 per cent.) on real estate and a capitation tax of 50 cts., the state expenses were defrayed up to that time. The total taxable property in 1858 was \$198,636,818, including 47,937,587 acres of land, valued at \$73,677,816; 43,690 town lots, \$12,861,990; 184,201 slaves, \$71,912,496; 238,203 horses, \$11,588,247; 2,220,438 cattle, \$13,259,537; and miscellaneous property, \$6,847,298. In 1859 the total taxable property was \$224,358,266, the increase being in the value of slaves, \$12,774,820; land, \$9,477,542; cattle, \$2,739,421; horses, \$2,617,502; town lots, \$1,388,984; money lent, \$518,047; and miscellaneous property, \$1,208,812. The total tax of 1859 was \$309,726.60, and the average value of land per acre was \$1.88. On Aug. 31, 1860, the funds in the state treasury were: revenue of state, \$127,984.02; university land sales, \$19,978.55; school fund, \$2,531,520.64; sinking fund on railroad bonds, \$28,920; special deposits, \$41,748.77; total, \$2,750,091.98.—The first European visitors to the shores of Texas were a colony of French emigrants led by the sieur de La Salle, who, designing to found a settlement in the delta of the Mississippi, sailed past it unawares, landed in Matagorda bay, erected Fort St. Louis on the Lavaca, and after a series of misfortunes was murdered near the Neches river by his own men in 1687. In 1689 Capt. De Leon, a Spanish officer, was despatched to the Lavaca to scour the country and hunt out the French. He arrived there on April 22, found the garrison scattered, and returned the next year with 110 men and some friars, and established on the site of Fort St. Louis the mission of San Francisco. In 1691 a Spanish governor of the region was appointed, and soldiers sent to enforce his authority; but in 1693 the hostility of the Indians, the failure of the crops, and the death of their cattle discouraged the colonists, and the settlement was abandoned. The Spaniards had settlements at El Paso

and at San Juan Bautista, both on the right bank of the Rio Grande, but none within the present bounds of Texas. In 1714 the French again attempted to effect a settlement within its limits, and Crozat, to whom Louis XIV. had granted the whole of Louisiana, sent Huchereau St. Denis upon an expedition thither. He penetrated from the Sabine to the Rio Grande, and visited the Spanish mission of San Juan, where he was taken prisoner by the governor of Coahuila; but having subsequently married the daughter of the commandant of that mission, he introduced Spanish missionaries into Texas, who established a mission on the bay of San Bernard, another west of the Sabine and near the coast (the famous mission of Dolores), and a third on the right bank of the San Pedro, near San Antonio, subsequently removed eastward, and known afterward as the Alamo. Two other missions were established soon after, one near Nacogdoches, the other not far from San Augustine. The name of "the New Philippines" was now given to the country, and in 1715 the marquis de Aguayo was made governor-general of the colony. For 20 years the Spaniards held sole sway over this colony, and multiplied their settlements. In 1735 St. Denis, who had acquired great influence over the Texas Indians, aided in removing a French settlement on the Red river into Texas; the Spaniards protested, but owing to quarrels among themselves did not drive them out, and finally conceded that they had a right to the region they were occupying. Texas did not prosper under its Spanish rulers, and in 1744 its European population did not exceed 1,500. In 1758 the Indians attacked the mission of San Saba, and killed all its inhabitants. This caused the decline of the missions in Texas, as the slaughter was never avenged. In 1763 the feud between France and Spain was finally settled by the cession of Louisiana by the former power to the latter; and up to the establishment of peace between the United States and Great Britain in 1783, there were no events of interest connected with its history. By treaty with Great Britain before the war of the American revolution, Spain had conceded the free navigation of the Mississippi, and the right to make New Orleans a place of deposit for goods *in transitu*. These privileges she was disposed to withhold from the United States, which had succeeded to the British title, from fear that they would lead to aggressions upon her territories along the gulf coast. For a long time war seemed imminent, but was finally averted by the difficulties of Spain at home. In 1803, Spain having re-ceded Louisiana to France, that power ceded it to the United States; and as there had been no well defined boundary between Louisiana and the old Spanish possessions W. of it, a controversy at once ensued between Spain and the United States on the question of boundaries, Spain claiming a region E. of the Sabine, and the United States urging that they were entitled to the country W. as far as the Rio

Grande. At one time the U. S. authorities drove the Spaniards across the Sabine, and for some time the troops of the two nations occupied the opposite banks of that river, and a collision seemed inevitable; this was finally averted, in Oct. 1806, by the prudence and discretion of Gen. Herrera, the Spanish commander, who entered into an agreement with Gen. Wilkinson establishing the territory between the Sabine and Arroyo Honda as a neutral ground, and retiring W. of that line. The illicit trade with Mexico carried on through Texas was so lucrative as to engage numerous adventurers in it, some of whom were captured and treated with great cruelty by the Spanish authorities; and as the relations of Spain with her American colonies were becoming very unsatisfactory, there were frequent attempts made to throw off the Spanish yoke both by Mexico and the settlers in Texas, many of whom belonged to this class of adventurers. From 1806 a series of revolutionary efforts commenced, beginning with the projected movement of Aaron Burr, and embracing the expeditions of Magee, a former lieutenant of the U. S. army; of Col. Kemper, his successor; of Bernardo Gutierrez; of Col. Ellis P. Bean, who had suffered a protracted and cruel imprisonment from the Spanish authorities; of Gen. J. A. Toledo, a Cuban republican; of Col. Perry, an American officer of considerable ability; of Auzy, who styled himself governor of Texas; and of Xavier Mina, a Spanish refugee, who aided in the capture of Galveston island in 1816. In these expeditions there were several severe battles fought between the invaders and the Spanish authorities; on two occasions in 1813, the invaders defeated the Spanish forces, and caused them a loss of more than 1,000 killed and wounded. These defeats were terribly avenged in the same year, when, of a force of 2,500 Americans and Mexicans, all were slain but about 100, a considerable number being butchered in cold blood, and nearly 700 of the peaceable inhabitants of San Antonio murdered. In 1817 Mina won several victories in conflicts with the Spanish troops, but was finally defeated, taken prisoner, and shot on Nov. 11 of that year. Col. Perry attempted to return by land to the United States; but having with a force of only 50 men demanded the surrender of La Bahia, a Spanish garrison, he was attacked in the rear by a troop of 200 royalist cavalry, and, all his men having fallen, New out his own brains with his pistol. After the close of the war of 1812 Lafitte, the pirate of the gulf, made Galveston island his headquarters, and established a town there named Campeachy. He also claimed to be acting under authority of the Mexican republic, and it is said actually received such authority from Col. Bean, one of the revolutionary leaders. He remained here till 1821, when, a naval force having been despatched by the U. S. government to break up the settlement, he abandoned Texas for ever. In 1819 the long con-

trovercy between the United States and Spain in regard to the Texas boundary was terminated by the cession of Florida to the United States and the establishment of the Sabine as the boundary line, with a guaranty to Spain of her possessions W. of that river. This treaty occasioned much dissatisfaction on the part of the western and south-western states. Mr. Clay and other prominent men opposed it. Another revolutionary expedition was organized at Natchez the same year, under the command of Dr. James Long, a Tennessean, which penetrated as far as Nacogdoches and established a provisional government there, and the leader went to Galveston island to secure the coöperation of Lafitte; but while absent his force was routed and cut to pieces by the royalist troops, and Long himself escaped with difficulty across the Sabine. In a second expedition he took possession of La Bahia without difficulty; but, though Mexico had become independent under the presidency of Iturbide, he and his followers were taken prisoners and sent to Mexico, where after a brief imprisonment he was set at liberty, but almost immediately assassinated, in 1832. Texas at this time was almost wholly deserted, the settlement at Galveston entirely abandoned, and the few inhabitants at other points reduced to poverty by the civil war which had so long existed. In 1820 Moses Austin, a native of Connecticut, but at that time a resident of Mexico, received from the Spanish authorities of Mexico a grant of lands in Texas for which he had petitioned a year previous; he died, however, before he was able to avail himself of it. His son, Stephen F. Austin, received a confirmation of the grant in April, 1823, having already in the beginning of 1822 conducted a considerable number of colonists to the site he had selected in the vicinity of the present county of Austin, and more soon followed. The grants of land to colonists were very liberal, 177 acres at least being given to each farmer, and a larger quantity if he had a family, and to each stock raiser 4,428 acres; the emigrants for the first 6 years were to be free from taxes, tithes, duties, &c. The founder of the colony, for each 200 families he introduced, was to receive 66,774 acres of land, but was limited to 8 times this amount however many families he might colonize. The colony increased rapidly, and Austin obtained permission to bring in 500 more families (his first grant was for 300). Others also followed in the establishment of colonies in the same vicinity. The Mexican constitution, adopted in 1824, united Coahuila, hitherto a separate province, with Texas in a single state, and the congress of the united state placed a Mexican as commandant of the department of Texas. The injustice of this commandant toward the American citizens, especially those attached to the colony of Haydon Edwards, adjacent to that of Austin, created difficulty; and an appeal being made to the governor of the state, who was also Mexican, he without trial or examination an-

nulled Edwards's grant and expelled him from the state. A band of American criminals, fugitives from justice who had settled in that vicinity, organized themselves into a company of "regulators" to harass the colonists who had taken up lands under Edwards and drive them from the farms they had improved. Thus oppressed, Edwards and his colonists attempted unsuccessfully to effect a revolution; and in Jan. 1827, they were compelled to retreat into the United States. A somewhat more liberal course was pursued by the Mexican authorities after this event, and the colonies prospered, though occasionally harassed by the Indians, whose forays injured their trade with Mexico. In 1830 Bustamante, who had seized the dictatorship of Mexico, issued a decree forbidding the people of the United States to enter Texas as colonists, and suspending all colony contracts which interfered with this prohibition. From this time forward the jealousy of the Mexican government against the emigrants from the United States became every month more manifest, and reckless and unprincipled adventurers, like Bean, Gaines, and Bradburn, who had long before become obnoxious to the government under which they were born and to good citizens everywhere, united with the Mexican government, or rather went beyond it, in acts of oppression and outrage upon the peaceable colonists. The Indians also were constantly becoming more and more ferocious and troublesome, and in several instances pitched battles were fought with them. In 1832 the Texans, sustaining the *pronunciamiento* of Vera Cruz in favor of the constitution, and in opposition to the rule of Bustamante, were attacked by a force sent by Bradburn to enforce the authority of that despot; but in the battle which followed the Mexicans were defeated with heavy loss. In 1833 the American settlers in the state, now numbering over 20,000, held a convention and determined to separate themselves from Coahuila, which was exclusively Mexican in its population, and accordingly prepared a state constitution and an address to the general government, of which Santa Anna was now the head, requesting admission in the capacity of a separate state into the republic. This movement was one in which the best men of Texas were all united. Col. S. F. Austin was one of the commissioners, and the only one who went to Mexico to present the request of the memorialists. He was unsuccessful, and was detained in Mexico till Sept. 1835, but in 1834 succeeded in procuring the revocation of the decree of Bustamante prohibiting the admission of colonists from the United States, and several other favorable concessions. Meantime the Mexican inhabitants of Texas and Coahuila had quarrelled, and each had set up a revolutionary government; but the Anglo-American residents remained quiet. Santa Anna sought to amuse Austin and the Texans with promises of allowing them a state government till he could occupy the state with

histroops. The state legislature, which had been in opposition to him, but which was guilty of great frauds and outrages, was broken up at the approach of his troops, and the state was without a government. The Texans must either maintain a government of their own, or submit to the dictator, who had already deceived them. They chose the former alternative, and established at first committees of safety, the first being appointed at a meeting at Mina (now Bastrop), May 17, 1835. Others followed, and on the return of Austin in September it became evident that war was inevitable. The first battle, or rather skirmish, was fought near Gonzales, Oct. 2. Other battles soon occurred; Goliad was captured by the Texans on Oct. 9, and the battle of Conception was fought on the 28th. Col. Austin was made commander-in-chief. On Nov. 12 the "Consultation," a body composed of delegates from the committees of safety, met at San Felipe de Austin, and proceeded to the organization of a provisional government. Henry Smith was elected governor and J. W. Robinson lieutenant-governor, and a general council was organized. At the same time, Gen. Austin having resigned, Gen. Sam Houston was elected commander-in-chief, and the former appointed a commissioner to the United States. San Antonio de Bexar was taken on Dec. 10, 1835, after being cannonaded for 6 days, and on the 14th Gen. Cos, the Mexican commander, started for Mexico with upward of 1,000 of the troops who had surrendered. By this battle the entire armed Mexican force was driven out of Texas. On the 22d a "Declaration of Independence" was issued at Goliad by Capt. Philip Dimitt and some other persons there. Santa Anna, on receiving intelligence of the surrender of Gen. Cos, at once determined upon active measures for the reduction of Texas, and set out with an army of 7,500 men well provided with artillery, ammunition, and stores. Gen. Houston had caused San Antonio de Bexar to be dismantled, and on Feb. 23, 1836, Santa Anna with a large detachment of his army invested the Alamo, a strong fort near San Antonio, which was garrisoned at this time by 140 men under command of W. B. Travis, and 32 more subsequently forced their way through the Mexicans into it. Santa Anna with a force of 4,000 men bombarded it for 11 days, and finally carried it by storm. On March 6 the whole garrison were put to the sword, and but 3 persons, a woman, a child, and a servant, were spared. The Mexican loss was 1,600. On the 17th of the same month the convention adopted a constitution and elected a president (David G. Burnett) and other officers of the new republic. Meanwhile Gen. Houston found it necessary on the approach of Santa Anna to evacuate Gonzales. The tragedy of the Alamo, the murder of Col. Fannin's command in cold blood at Goliad, March 27, 1836, by Santa Anna's order, in violation of the terms of surrender (see FANNIN), and the successive defeats of the

Texan troops, produced a temporary panic. This was increased by the continued retreat of Gen. Houston, who fell back first to the Colorado, then to the Brazos, and finally to the San Jacinto, his design being to scatter and divide the Mexican force, in which he was eminently successful. The alarm soon passed away, and having collected a force of about 800 troops, he gave battle on April 21 to the Mexican forces which had pursued them, of about twice the number, and defeated them completely, killing 630, wounding 208, and taking 730 prisoners; among the latter (though not captured till the next day) was the Mexican president, who had commanded in person. Santa Anna, at Gen. Houston's request, sent an order to Gen. Filisola, who was on the Brazos, directing him to fall back to Bexar, and to direct Gen. Urrea to retire to Guadalupe Victoria, and not to molest the Texans, as he had agreed upon an armistice. The Mexicans were at once demoralized by the defeat and half starved, for the Texans had taken the vessels sent with supplies. They retreated rapidly westward in disorder; and when the Texan commissioners arrived at the Mexican camp with the treaties into which Santa Anna had entered with the Texan provisional government, agreeing to withdraw all troops from Texas, and to open the way for negotiation for the recognition of her independence, asking its ratification on the part of Gen. Filisola and its transmission through him to the Mexican government, the Mexican army was by no means formidable. Santa Anna was held a prisoner, but the war was practically ended; and though the Mexican government made several attempts to fit out other armies for its recapture, and refused to acknowledge its independence, their armies did not again invade the country. The population of the state had increased to about 52,000, and the intelligence of the massacres at the Alamo and Goliad had enlisted so much sympathy for the Texan cause in the United States that considerable bodies of troops had come in to aid them. Gen. Houston, who had been wounded in the battle of San Jacinto, and had resigned his command of the army, was, in Sept. 1836, elected to the presidency of the republic, and on Oct. 22 was inaugurated. The first congress of the republic assembled at the same time, the constitution having been adopted in the election of September. In March, 1837, the United States acknowledged the independence of Texas. Mexico yet maintained a hostile attitude, but her efforts were confined to occasional captures of Texan vessels, and to the stimulation of the Indians to make predatory incursions upon them; and both these methods of annoyance led to reprisals in kind. In 1838 Mirabeau B. Lamar succeeded Gen. Houston as president of the republic. During his administration an agent of the Mexican government to the Indian tribes at the north, with some of his guard, was killed, and from the commissions found in his possession it was discovered that

that government was endeavoring to incite the Indians to commence a harassing and destructive warfare all along the frontier. The timely discovery of this design prevented its execution. There were, however, repeated incursions made by the Comanches and other tribes; and in Aug. 1840, the Texans under the command of Ben McCulloch (subsequently distinguished as the commander of the Texan rangers in the Mexican war, and as a general of the confederate forces in the civil war of 1861-'3, and killed at the battle of Pea Ridge in Arkansas, March 8, 1862) pursued them after one of their forays, penetrated into their country, and in several successive conflicts inflicted upon them summary and severe punishment. In 1840 the independence of the republic was acknowledged by England, France, and Belgium. But while thus recognized by leading powers as independent, her financial condition was every month becoming more deplorable. The debt, in Oct. 1840, was \$4,822,318, and the treasury notes had become depreciated to 12 or 15 cents on the dollar. Various plans of relief were proposed, and at one time Gen. Hamilton, the agent of the republic in France, had as he supposed negotiated a loan with the banking house of Lafitte and co. there; but owing to some differences between the French consul at Galveston and the Texans, he did not succeed in completing it. Finding their credit at the lowest possible ebb, Gen. Houston, who had again become president in Dec. 1841, recommended the abandonment of all attempts to borrow, the suspension of their debt, the reduction of all expenses, and the payment of duties in specie or par funds. A part of these recommendations were adopted, but with little relief. Meanwhile, in 1841 and 1842, the Mexican government sent two marauding expeditions into Texas, one of which captured and plundered San Antonio, and then retreated rapidly, making no attempt at subjugating the country. The Texans attempted reprisals by two ill-judged expeditions, neither of them under the direction of the government, the first in 1841 to Santa Fé, the second in 1842 to Mier in the Mexican state of Tamaulipas. Both were unsuccessful; many of the Texans were taken prisoners by the Mexicans, and subsequently executed. In the Mier expedition 18 were shot in cold blood by the order of Santa Anna. In the spring of 1843 a third expedition, intended to intercept the Mexican traders to Santa Fé, was fitted out by private parties, but with the approbation of the government, which also proved a failure. The same year, on the remonstrance of the British chargé d'affaires to Mexico, Santa Anna, who was still in power, informed Gen. Houston that he would agree to an armistice; and commissioners were appointed on both sides. While the negotiations were pending, President Tyler, through his secretary of state, Mr. Upshur, made propositions to the president of Texas for her annexation to the United States, which were after a time favor-

ably received, and a treaty was made looking to annexation. This treaty was completed and signed by the Texan commissioners and Mr. Calhoun, April 12, 1844, but was rejected by the United States senate on June 8. The agitation of this subject greatly irritated Mexico, and caused her to terminate the armistice and threaten the renewal of hostilities; it also displeased Great Britain and France, who desired to see Texas under an English or joint protectorate, without slavery, and free from the influence of the United States. The rejection of the annexation treaty therefore delighted those parties, while for the time it placed Texas in a humiliated position. In Dec. 1844, Dr. Anson Jones was inaugurated as president of the republic. The state in its internal affairs was becoming more prosperous. Its revenues were increasing, and its population growing with great rapidity, and the threats of war from Mexico were rendered powerless by her weakness and dissensions. The only disturbance within the boundaries of the state was the conflicts between the "regulators" and "moderators," two bodies of ruffians, murderers, counterfeiters, horse thieves, and the like, numbering nearly 300 each, who were engaged in Shelby and the adjacent counties in plundering, robbing, and killing peaceful citizens, and the members of the gang opposed to them. These were finally put down by armed force. In the session of the U. S. congress following the election of Mr. Polk to the presidency, joint resolutions for the annexation of Texas were introduced and passed the house of representatives, by a vote of 120 to 98, Feb. 25, 1845, and the senate by a vote of 27 to 25 on March 1, and were approved by President Tyler the same day. President Jones called a convention of 61 delegates to meet on July 4 to consider the propositions for annexation, and that convention ratified the act and prepared a constitution for the republic as a state of the federal Union, which was submitted to the people and approved by them. The joint resolution by which the annexation was effected was in the following words:

"That congress doth consent that the territory properly included within, and rightfully belonging to the republic of Texas, may be erected into a new state, to be called the state of Texas, with a republican form of government, to be adopted by the people of said republic, by deputies in convention assembled, with the consent of the existing government, in order that the same may be admitted as one of the states of this Union. And, that the foregoing consent of congress is given upon the following conditions, and with the following guarantees:

"First. Said state to be formed, subject to the adjustment by this government of all questions of boundary that may arise with other governments; and the constitution thereof, with the proper evidence of its adoption by the people of said republic of Texas, shall be transmitted to the president of the United States, to be laid before congress for its final action, on or before the 1st day of January, 1846.

"Second. Said state, when admitted into the Union, after ceding to the United States all public edifices, fortifications, barracks, ports and harbors, navy and navy yards, docks, magazines, arms, armaments, and all other property and means pertaining to the public defence belonging to said republic of Texas, shall retain all the public funds, debts, taxes, and dues of every kind which may belong to, or be due and owing said republic; and shall also retain all the vacant and unappropriated lands lying within its limits, to

be applied to the payment of the debts and liabilities of said republic of Texas; and the residue of said lands, after discharging said debts and liabilities, to be disposed of as said state may direct; but in no event are said debts and liabilities to become a charge upon the government of the United States.

"Third. New states, of convenient size, not exceeding four in number, in addition to said state of Texas, and having sufficient population, may hereafter by the consent of said state be formed out of the territory thereof, which shall be entitled to admission under the provisions of the federal constitution. And such states as may be formed out of that portion of said territory lying south of thirty-six degrees thirty minutes north latitude, commonly known as the Missouri compromise line, shall be admitted into the Union with or without slavery, as the people of each state asking admission may desire; and in such state or states as shall be formed out of said territory north of said Missouri compromise line, slavery or involuntary servitude (except for crime) shall be prohibited."

The state of Texas was admitted into the Union on Dec. 27, 1845. After its admission, which led to a war with Mexico, it found itself unable to pay its debts from the proceeds of its public lands, and on Aug. 2, 1850, congress, as one of the compromise measures of that year, voted to pay to the state \$10,000,000 in 5 per cent. bonds, payable 14 years after date, in consideration of the reduction of her boundaries (by giving up a portion of her northern territory to New Mexico), cession of territory, and relinquishment of claims against the United States. With the proceeds of these bonds she paid off her debts, averaging 79 cents on the dollar on the claims against her. Soon after the presidential election in 1860 there were indications in some of the E. counties of a desire for secession from the United States; but Gov. Houston refused to call a convention to consider the subject, and declared that secession would prove the ruin of the state. A call for a convention, signed by 61 persons, was published, and to avoid a collision Gov. Houston called an extra session of the legislature for Jan. 22, 1861. The legislature, in opposition to his views, sanctioned a convention, but required that if a secession ordinance was passed it should be submitted to the people. The convention assembled on Jan. 28. Nearly one half the counties of the state, some of them among the most populous, held no election for it, and were not represented; and in many of those which elected, not over $\frac{1}{2}$ or $\frac{1}{3}$ of the voters of the county took part at the polls. The ordinance of secession was passed by this convention on Feb. 5, by ayes 166, noes 7. It was to be submitted to the people on Feb. 28, except in El Paso co., where it was to be submitted on the 18th. The convention then adjourned to Feb. 20. Meantime the legislature authorized the issue of state bonds to the amount of \$500,000, and of treasury warrants receivable for taxes. The governor, on the passage of the secession ordinance, published an address protesting in the name of the people against all the acts and proceedings of the convention. The convention on reassembling, by a vote of 127 to 4, deposed the governor and secretary of state, and directed the lieutenant-governor to take the place of the governor. This done, they adjourned on Feb. 25. The secession or-

dinance was said to have been passed by a large majority. Early in Feb. 1861, Gen. David E. Twiggs indicated to the convention his willingness to surrender to the state, or rather to the secession party in the state, the arms, ammunition, stores, horses, mules, wagons, and money in his possession belonging to the United States; and on the 18th an agreement was entered into between him and commissioners appointed by the state for such surrender. By this act, 13 forts, 15,000 stand of arms, 80 pieces of ordnance, \$55,000 in specie, about 1,300 horses, and mules, wagons, tents, provisions, ammunition, and munitions of war to the estimated value of nearly \$2,000,000, were given up. By the agreement, the U. S. soldiers and subordinate officers, 2,500 in number, were to be allowed their arms and furnished with transportation that they might leave the state without hindrance or pledge; but this agreement was broken, and they were all taken prisoners, stripped of their arms, and only released on parole not to serve against the confederate states. In June the acting governor (Clarke) issued a proclamation forbidding any citizen of Texas to hold intercourse with any of the northern states or territories, without special permission, or to pay any debt then owing to any citizen of those states during the war. All citizens of northern states were warned to depart from the state within 24 hours. On Aug. 2 and 5 the confederate vessels in the harbor of Galveston fired at the blockading fleet, which in return fired at them and threw 3 or 4 shells into the city. This was represented as a bombardment of the city, and the French and English consuls formally protested against it. During the early part of the autumn a force of about 700 Texan soldiers penetrated into the southern portion of New Mexico, and captured a fort garrisoned by U. S. troops; they were subsequently reinforced by other parties from Texas, and attempted to conquer the whole territory; but in March, 1862, they were driven back with heavy loss and great suffering. Texas contributed a large number of troops to the confederate army; and one of its most successful generals, Ben McCulloch, long identified with the history of the state as a partisan leader, was killed at the battle of Pea Ridge, in Benton co., Ark.

TEXAS, a S. co. of Missouri, drained by Current river and affluents of the Gasconade: area, 1,250 sq. m.; pop. in 1860, 0,069, of whom 56 were slaves. The surface is hilly, with large forests of yellow pine, and the soil fertile along the streams. The productions in 1850 were 112,042 bushels of Indian corn, 2,848 of wheat, and 5,957 of oats. There were 15 saw mills, 8 churches, and 20 pupils attending a public school. Capital, Houston.

TEXEL, a Dutch island of the North sea, in the province of North Holland, separated from the mainland by the channel called Mars-Diep, about 2 $\frac{1}{2}$ m. broad; lat. of W. point 53° 3' N., long. 4° 42' E.; extreme length 14 m., breadth

6 m.; pop. 5,600. It contains several villages, the most important of which is Barg. The surface is low and a great deal of it marshy, but it is protected from inundations by the line of dunes or sand hills on the W. side, and strong dikes in other parts. The soil is remarkably fertile, and is chiefly occupied by pastures. Several naval engagements have taken place near this island.

TEZOOOO, or Tezucuo, a town of Mexico, in the state and about 16 m. E. N. E. from the city of Mexico, situated on the E. shore of the lake of the same name; pop. about 5,000. Woollen and cotton goods are manufactured, and a considerable trade is carried on. In ancient times Tezucuo was the second city in the kingdom. One of the palaces of Montezuma is said to have stood in the N. W. quarter, and in the S. part there are massive remains of 3 pyramids, each measuring 400 feet along the base of their fronts, which are thought to have been *teocallis*, devoted to human sacrifices.

THACHER, JAMES, M.D., an American physician and author, born in Barnstable, Mass., Feb. 14, 1754, died in Plymouth, May 26, 1844. He commenced the study of medicine at the age of 16, and on the breaking out of the revolution was appointed surgeon's mate to Dr. John Warren in the general hospital at Cambridge; in 1778 he was made chief surgeon to the 1st Virginia state regiment, and in 1779 was transferred to the same post in a New England regiment. Throughout the war he kept a diary, and was thus enabled in 1834 to disprove the charges brought against our army and Gen. Washington by Mr. Buchanan, British consul at New York, of André's regimentals having been purloined. In March, 1788, he established himself in his profession at Plymouth, Mass., where he also gave some attention to the manufacture of salt and iron. In 1810 he first became known as an author by the publication of the "American New Dispensatory," which was long a standard work on pharmacy, medical chemistry, and materia medica. This was followed by "Observations on Hydrophobia" (8vo., 1812); "The Modern Practice of Physic" (1817; 2d ed., 1826); "The American Orchardist" (1822; 2d ed., 1825); "A Military Journal during the Revolutionary War" (1823; 2d ed., 1827); "American Medical Biography" (2 vols. 8vo., 1828); "A Practical Treatise on the Management of Bees" (1829); "An Essay on Demonology, Ghosts, and Apparitions" (1881); and other works.

THACHER, PETER, D.D., an American clergyman, born in Milton, Mass., March 21, 1752, died in Savannah, Ga., Dec. 16, 1802. He was graduated at Harvard college in 1769, and settled at Malden, Mass., in 1770. He soon attained a high reputation as a preacher, and received the name of the "silver-tongued Thacher." From Jan. 1785, till his death, he was the pastor of the Brattle street church in Boston. He was active and earnest as a patriot during the revolution, and his "Oration

against Standing Armies," delivered at Watertown in 1776, has retained its reputation to the present time. In 1780 he was a member of the convention to form a constitution for the state, and for 15 years he was chaplain of one or both branches of the legislature. The university of Edinburgh conferred on him the degree of D.D. in 1791. He published 22 distinct works, among which were "Observations on the State of the Clergy in New England" (1783), and "Memoirs of Dr. Boylston" (1789). —SAMUEL COOPER, an American clergyman, son of the preceding, born in Boston, Dec. 14, 1785, died in Moulins, France, Jan. 2, 1818. He was graduated at Harvard college in 1804, and in 1811, when the Rev. Dr. Kirkland was elected president of Harvard university, Mr. Thacher was chosen his successor as pastor of the New South church in Boston. In 1817 he again visited Europe for the benefit of his health, but died of consumption soon after reaching Moulins. He was one of the association for conducting the "Monthly Anthology," and published a memoir of his friend, the Rev. Joseph Stevens Buckminster. After Mr. Thacher's death a volume of his sermons, with a memoir by the Rev. F. W. P. Greenwood, his successor in the ministry, was published.

THACKERAY, WILLIAM MAKEPEACE, an English novelist, born in Calcutta in 1811. Descended from an old family of Yorkshire that has given several rectors and scholars to the church of England, his grandfather was rector of Hadley in Middlesex, and his father was engaged in the civil service of the East India company. He was sent to England in his 7th year, had a view of Napoleon at St. Helena on his way, and was placed at the Charterhouse school in London. From the Charterhouse he went to the university of Cambridge, but did not take his degree; inherited a fortune of £20,000 on coming of age; chose art for his profession; and travelled and studied for several years in France, Italy, and Germany. In 1830-'31 he lived at Weimar, saw Goethe, purchased Schiller's sword, and delighted in making caricatures for children, some of which he found still preserved on revisiting the place in 1853. Reminiscences of his early art studies are interwoven into his fictions, many of which are illustrated by his own pencil; but he abandoned the project of becoming a professional artist soon after his return to England. His fortune was greatly reduced by losses and unsuccessful speculations, and before his 30th year he had set himself resolutely to literature as his vocation. His progress to general recognition was slow, though from the first he gave signs of his peculiar powers. He is understood to have written for the "Times" while it was edited by Barnes, and was certainly connected with other London journals. He contributed to "Fraser's Magazine," under the pseudonyms of Michael Angelo Titmarsh and George Fitz-Boodle, Esq., a variety of tales, criticisms, descriptive sketches, and

verses, which proved his knowledge of the world, delicate irony, and mastery of a playful yet vigorous style. In this periodical appeared "The Great Hoggarty Diamond" in 1841, a thoroughly genial satire, with a tone at once of ridicule and of pathos. His earliest separate publications, also under the pseudonym of "Titmarsh, literary cockney and sketcher," were "The Paris Sketch Book" (2 vols., 1840); "The Second Funeral of Napoleon" and "The Chronicle of the Drum" (1841), the latter being one of his finest metrical pieces; and "The Irish Sketch Book" (2 vols., 1843). None of these attained popularity, though the last has some of the happiest touches both of his pen and pencil. Meantime "Barry Lyndon," one of the best of his short tales, narrating the adventures of an Irish gambler and fortune-hunter, was contributed by Fitz-Boodle to "Fraser." The establishment of "Punch" in 1841 opened to him a new field, and his papers in this periodical speedily acquired peculiar distinction. His first series, under the signature of "The Fat Contributor," were followed by "Jeames's Diary," in which he looks at society from the footman's point of view, and "The Snob Papers," which gave to him an independent reputation as a social satirist, while they added to the success and dignity of "Punch." Many of his contributions were in verse, and showed his dexterous command of rhyme and of ludicrous orthography. A journey which he made to the East for his health suggested his "Notes of a Journey from Cornhill to Grand Cairo, by way of Lisbon, Athens, Constantinople, and Jerusalem, by M. A. Titmarsh" (1846); and he issued in the following year a small Christmas book entitled "Mrs. Perkins's Ball." Meantime "Vanity Fair," illustrated by himself, was published in numbers (1846-'8). When it began, his name was still generally unknown, but its popularity increased with every number, and at its close he was universally accounted with Dickens and Bulwer among the first British novelists. It is more strongly marked by special and peculiar genius than any other of his works, and is pre-eminent also in the delineation of character. Becky Sharp and Amelia Sedley, one the impersonation of intellect without affection, and the other of affection without intellect, are original characters, thoroughly and sagaciously drawn; the wickedness of the one is made amusing, and the weakness of the other pathetic; and cruel sarcasm, sparkling *periphrase*, and soft compassion succeed each other as he traces the desperate enterprise of Becky and half sneers at the unflinching tenderness of Amelia. Upon the completion of "Vanity Fair" he published another Christmas book, "Our Street" (1848), to which a companion volume, "Dr. Birch and his Young Friend," was added in the following year. He had already begun another monthly serial, "The History of Pendennis, his Fortunes and Misfortunes, his Friends and his Greatest Enemy, with Illustrations by the Author." He

aimed in this, his second great work, to describe the gentlemen of the present age, "no better nor worse than most educated men." Arthur Pendennis is a young fellow of warm feelings and a lively intellect, self-conceited and selfish, with no attractive points of character but a sense of honor and a capacity for love. He is carried away by absurd passions, falls a victim to vanity and weakness, takes to literature, becomes a man of the world and of fashion, and lives from hand to mouth without ambition, convictions, or any object beyond the chance requisitions and excitements of the day. The author invites us, "knowing how mean the best of us is," to give a hand of charity to him "with all his faults and shortcomings, who does not claim to be a hero, but only a man and a brother." A higher moral tone appears in the characters of Warrington and Laura. "Pendennis" was concluded in 1850, and his Christmas book of that year was a reprint from "Fraser" of a mock continuation of Scott's "Ivanhoe," entitled "Rebecca and Rowena." He published an original Christmas tale for the next year, "The Kickleburs on the Rhine," a clever and kindly satire on a proud and vulgar family travelling on the continent, but which a critic in the "Times" newspaper severely reviewed, charging the author with preferring to look only on the ugly side of human nature, and with overlooking the virtue and amiability that exist in the world. Mr. Thackeray repelled and ridiculed the accusation in an "Essay on Thunder and Small Beer," prefixed to the second edition of the volume. In the summer of 1851 he lectured in London before brilliant audiences on "The English Humorists of the 18th Century," sketching the lives and works of his predecessors in English fiction from Swift to Goldsmith. The lectures were repeated and admired in Scotland and America, were published in 1853, and have a peculiar charm from the sympathetic and social portraiture of his "fellows" of the past, mingling fine thoughts and amusing anecdotes. Ten thousand copies of a cheap edition were sold in a week. His attention had been called to the wits of Queen Anne's reign by studies preparatory to the "History of Henry Esmond, Esq., written by Himself" (1852), the scene of which is laid in that era. This is the most artistically complete and the noblest in tone of all his works, while it also admirably copies the manners, sentiment, and diction of the Queen Anne period. The main characters, Esmond and Beatrix, are among his best creations—the former a strong, high-minded, disinterested, and impulsive cavalier and Jacobite, and the latter perhaps the finest picture of splendid, lustrous physical beauty ever given to the world. It is a magnificent and sombre romance, comparing with his other works as "The Bride of Lammermoor" to the others of Scott. His third serial novel was "The Newcomes: Memoirs of a Most Respectable Family, edited by Arthur Pendennis, Esq.," the issue

of which was completed in 1855. In this the elements are more kindly mixed than in any other of his fictions; there is a softening of tone, a predominance of feeling over sarcasm, an avoidance of the darker tints and baser qualities which he had previously favored as themes for smiling railery. The characters of Olive and Ethel are less vivid than some of his others, but the story lingers, and the whole is redeemed by its prevalent genial spirit, and especially by the moral beauty of the life of Colonel Newcome, and by his death in the Charterhouse, than which there is nothing more touching in romantic literature. His earlier contributions to "Fraser," "Punch," and other journals were now collected under the title of "Miscellanies," and his admirers were interested in tracing the gradual development of his genius. The same secular power, at once cynical and cheery, and the same clear, idiomatic, and effective style, mark the best of his earlier burlesques and his later elaborate productions. The success of his lectures on the humorists induced him to prepare another series, "The Four Georges," which were first delivered in the principal cities of the United States in 1855-'6, and afterward in London and most of the large towns in England and Scotland. The courts and characters of the Hanoverian monarchs furnished abundant occasion for satire; the third George alone, especially in the misfortunes of his last years, was discussed with forbearance and described with pathos; and the literature, society, morals, and manners of the time were briefly illustrated. Thackeray had entered himself at the Middle Temple and been called to the bar in 1848, but with no intention of following the legal profession. In 1857, one of the seats for the city of Oxford in the house of commons having been declared vacant, he offered himself as the liberal candidate for the representation, and declared himself an advocate of the ballot and of the diminution of the official influence of the hereditary aristocracy, but was defeated by Mr. Cardwell, by a majority of 67 votes. Before the close of the year he had begun another serial, "The Virginians," the scene of which is laid in the last century during the later years of George II. and the earlier years of George III., and in which Chesterfield, Garrick, and Johnson, the gaming table and coffee house, Washington, Wolfe, Braddock, and the impending American war, are introduced together with fictitious personages and events. The work holds an interesting place between "Esmond" and "Pendennis," some of its characters being descendants of those in the former, and ancestors of those in the latter. It is rather loosely constructed, but abounds in philosophic humor and irony. In Jan. 1860, appeared the first number of the "Cornhill Magazine," under the editorial charge of Thackeray, which soon attained a circulation of some 100,000 copies. In this periodical he has published "Level the Widower," the least esteemed of

his later novels, and his lectures on the four Georges; and he is now (1862) producing in its pages a new romance entitled "The Adventures of Philip on his Way through the World."—The characters of Thackeray are generally described, not by their great qualities or leading habits, but by small peculiarities, affectations, or weaknesses. The literary barristers in "Pendennis," for example, do not appear as having much to do with either law or literature; Warrington, who produces the impression of being a man of powerful thought, does nothing to give it scope; we learn it only from his conduct in the commonest affairs of life. He shows no more of his personages than might be gathered from intercourse in society, paints men almost entirely in their moments of relaxation, relates their behavior, and displays so much of their feelings as their demeanor, actions, and voice can bear witness to. His aim is not to give clues to a character, but to reproduce the image which the whole phenomenon of society has impressed on his mind. To read him is therefore like meeting and mixing with the individuals in actual life. His field of survey is not very broad, his favorite position being the debatable land between the aristocracy and the middle classes. He knows mankind from dining rooms and drawing rooms, club rooms and country houses. Without any thorough acquaintance with English provincial life, or with the habits and feelings of the lower classes, he has seen a good deal of soldiers, artists, and men of letters, and has a profound knowledge of footmen and men about town. From false taste, or from some deeper infirmity, he inclines to give prominence to blots, parade defects, hold up the most petty and ignoble sides of all things, and find the comic aspect of wickedness and misery. But the unmistakable irony of his realistic descriptions necessarily implies and suggests an ideal of humanity from which his heroes are deviations; and from this moral antithesis of the actual and ideal springs the peculiar charm of his writings, the mingled gayety and earnestness, sentiment and cynicism, pathos and sarcasm, tenderness and malignity, with which he regards human life.

THAER, ALBRECHT, a German agricultural writer, born in Celle, Hanover, May 14, 1752, died at Mögelin, near Potsdam, Prussia, Oct. 26, 1828. He studied medicine at Göttingen, and after a visit to England published "Introduction to the Knowledge of English Agriculture" (8 vols. 8vo., Hanover, 1798), which has passed through several editions. In 1799 he founded an agricultural school at Celle, and in 1806 the king of Prussia granted him a large tract of land, which he exchanged for another at Mögelin, where in 1807, he founded a practical school of agriculture, which in 1810 was constituted the royal school of agriculture. At the reorganization of the Prussian government in 1807, he was appointed a councillor of state, and carefully revised the land laws of the kingdom; and in 1810 he was appointed pro-

essor of agriculture in the university of Berlin. He published agricultural periodicals under various titles from 1798 to 1824. His great work, "The Rational Principles of Agriculture" (4 vols., Berlin, 1809-'10), has been translated into English and almost all the other languages of Europe. He received orders of knighthood from Russia, Prussia, Saxony, Bavaria, and Württemberg; and agriculturists regard him as the first to apply the principles of natural science to the practice of agriculture.

THAIS, an Athenian *hetaira* or courtesan, who accompanied Alexander the Great on his expedition to Asia. The celebrity connected with her name is chiefly due to the fact that she is said to have instigated Alexander to set fire to the citadel of Persepolis, the residence of the Persian kings, in revenge for the injuries done to her native city by Xerxes; but this anecdote, though immortalized by Dryden, is probably untrue, as we know on the authority of Arrian that it was his intention to sack the place and burn the citadel on grounds of state policy. After the death of Alexander, Thais became the mistress of Ptolemy Soter, and, according to Athenæus, was afterward married to him. She was celebrated for wit and repartee, and many anecdotes are recorded of her talent in those respects.

THALBERG, SIGISMUND, a Swiss pianist, born in Geneva, Jan. 7, 1812. He is the natural son of Count Dietrichstein, and while a boy was placed under the instruction of Hummel, whom he subsequently surpassed in firmness of touch and grace of expression. At 15 he began to be known in the concert rooms, and soon afterward published his first compositions. Since 1830 he has been constantly employed in giving concerts in the chief cities of Europe and America, and he divides with Liszt the honor of standing at the head of living performers on the pianoforte. His playing is distinguished by precision, delicacy, and finish, rather than by the production of surprising effects; but his chief merit, both as a performer and a composer, consists in his successful attempts to combine the elements of song and harmony and of brilliant execution, as exemplified respectively in the schools of Mozart and Beethoven and of Clementi. In connection with this movement he has discovered many ingenious combinations for the fingers, whereby the song or melody can always be heard strongly accented in the midst of rapid passages and complicated forms of accompaniment. Among the productions by which Thalberg and his method have acquired their celebrity are a series of fantasias of great beauty and brilliancy, including those on themes from *Don Giovanni*, *Robert le Diable*, *L'elisir d'amore*, *Les Huguenots*, *La donna del lago*, and *Moss en Egitto*, the performance of any one of which by the composer may be said almost to realize the perfection of pianoforte playing. His "Studies" for the pianoforte are also highly esteemed by instructors. In 1851 he produced

at London an opera entitled *Florinda*, founded on a libretto by Scribe, and which failed to attract much attention. In 1845 he married a daughter of Lablache.

THALER (Dutch, *dahler*; Dan. and Swed. *daler*), a coin and money of account of Germany, Austria, Holland, Belgium, Denmark, Sweden, and Norway. Silver coins of an ounce weight were struck in the early part of the 16th century at Joachimsthal, a valley in Bohemia, whence the name. (See DOLLAR.) Other countries after a time began to coin thalers, but not always of the same value, and hence originated the *Laubthaler* or leaf dollar, the *Philippsthaler*, the Swedish copper dollar, &c. In most of the countries of Europe the royal or imperial mints coined thalers, hence called *rigsdaler*, *rikedaler*, or *rigsthaler*, that is, dollar of the realm. These varied in value according to the amount of alloy. In Austria the specie rigsthaler is worth \$1.01; in Prussia and Brunswick, 72 cts.; in Hanover, 72.2 cts.; in Hesse-Darmstadt, 72.3 cts.; in Saxony, 72.3, and those coined from 1829 to 1836, \$1.008; in Denmark and Norway, \$1.09; in Sweden, coinage of 1830-'38, \$1.104. As money of account there is still greater diversity of values, owing to the depreciation of the issues of the national banks or treasuries. In Sweden the *rigsdaler banco* is 39½ cts., and the *rigsdaler riksmunt*, now the authorized money of account, is 34 cts. In Denmark the *rigsbank daler* is 54.7 cts. In Germany generally the *thaler* of account is reckoned at 69 to 72 cents American currency.

THALES, a Greek philosopher, and one of the 7 wise men, born in Miletus, Ionia, about 636 B. C., died probably about 546. He took an active part in the political affairs of his native country, and before Ionia fell under the Persian yoke he advised a federation of all the Ionian states. He visited Crete and Egypt, and acquired in the latter country an acquaintance with mathematics and geometry. Various physical discoveries are attributed to him. He measured the height of the Egyptian pyramids by observation of the time at which a shadow equalled in length the height of the object; and he is said to have computed the sun's orbit, to have fixed the length of the year at 365 days, and to have been the first among the Greeks to predict eclipses, though very vaguely. In philosophy he is generally considered the founder of the Ionian school. His speculations were principally upon the nature of the universe. He taught that all things are instinct with life, and that the origin of all things is water. He left no written works, but many of his sayings are recorded by Diogenes Laertius.

THALIA, in Greek mythology, the muse of comedy and idyllic poetry. She is generally represented with the comic mask, a shepherd's staff, or a wreath of ivy.

THAMES, a river of Connecticut, formed by the junction of the Quinebaug, Shetucket, and Yantic rivers at the city of Norwich, and

flowing thence S. about 14 m. to Long Island sound, which it enters below New London. It is a wide and beautiful river, navigable for large vessels to Norwich, and has an excellent harbor at its mouth. The streams which form it possess numerous valuable mill sites, and the large amount of manufactured goods from the factories on their banks make the Thames an important avenue of commerce.

THAMES, a river of Canada West, flowing through a fertile country in the peninsula formed by Lakes Huron and Erie, and after a S. W. course of about 160 m. discharging its waters into Lake St. Clair. It is navigable for boats from its mouth to Chatham, and has several considerable towns on its banks. At the Moravian settlement on this river, Oct. 5, 1818, the battle of the Thames was fought between the British under Gen. Proctor, with an auxiliary force of 2,000 Indians led by the famous Indian chief Tecumseh, and the American forces under Gen. W. H. Harrison. The American cavalry, commanded by Col. Richard M. Johnson, opened the battle, and defeated the enemy. Tecumseh was killed, and 600 prisoners, 6 pieces of cannon, and large quantities of stores were taken by the Americans.

THAMES, or Isis, the largest and most important river of England. Its source, called Thames Head, is in the Cotswold hills, about 3 m. S. W. from Cirencester. In the first 30 m. of its course it receives 3 small streams, the Churnet, the Coln, and the Lech, and below Lechlade becomes navigable for barges; from Lechlade its course is first E. and then N. N. E. and S. S. E. to Oxford, through a level country, receiving on its way the Windrush and the Cherwell. From Oxford to Reading it flows first S. S. E. and then S. E., receiving the waters of the Thame and the Kennet; thence making a considerable circuit to the N. by Henley, Great Marlowe, and Maidenhead, it turns eastward to Windsor, then makes a detour southward by Staines and Chertsey to Kingston, where it turns N., and, passing Richmond, reaches Brentford, whence its course is nearly due E. to its mouth. From Brentford it passes by Putney, Hammersmith, and Chelsea to London, receiving in its course the Loddon, Colne, Mole, Cran, Brent, and Wandle, all small streams. From London to its mouth, a distance of 54 m., the Thames is a large stream navigable for vessels of 700 or 800 tons, and for vessels of 1,400 tons to Blackwall, 6 m. below. It is 290 yards wide at London bridge; at Woolwich, 9 m. below, 490 yards; at Coalhouse point, 20 m. further down, 1,290 yards; at the Nore, 6 m.; and at its mouth, 18 m. Below London it receives the Ravensbourne, Roding, Darent, and Medway. Its tide is perceptible as far as Teddington, 79 m. above its mouth. Its commercial importance is increased by the canals which connect it with other navigable waters of England, viz.: the Thames and Severn canal, connecting it with the Severn, which discharges into Bristol chan-

nel; the Oxford canal, which connects it with the grand canal system of the central counties; the Wilts and Berks and the Kennet and Avon canals, which connect it with the Avon and the Severn; the Wey and Arun and the Basingstoke canals, connecting it with the Sussex coast; the grand junction, the Regent's, and the Paddington canals, the first of which connects the Brent with the Oxford canal, and the other two encircle the N. and E. sides of the metropolis and greatly facilitate the transportation of goods. The whole course of the Thames is 220 m. It forms the boundary between Gloucestershire and Wiltshire, between Berkshire and Oxfordshire and Buckinghamshire, between Middlesex and Surrey, and between Essex and Kent. The commerce of the Thames is surpassed probably by that of no river in the world. Its waters at and below London are crowded with vessels of all sizes and freighted with the products of all climes. Its vast and commodious docks for the discharge of goods from shipboard are described in the article DOCK. It is crossed at and above London by numerous bridges, while the tunnel which passes beneath its waters from the Middlesex side to Rotherhithe on the Surrey side, completed in 1840, is one of the most remarkable triumphs of Sir M. I. Brunel's engineering ability. (See LONDON, vol. x. p. 655.)

THANE, the name of an ancient rank among the Anglo-Saxons, derived from *thegnian*, to serve, and originally applied to the followers of kings and chieftains. In the later age of Anglo-Saxon rule there were two classes of thanes, those of the inferior sort being simply called thanes, those of the superior king's thanes. The former were exceedingly numerous. In rank the thane was below the *ealdorman* or earl, but the possession of landed property was essential to his dignity. The rank was attainable by all, even the servile; and the laws state the requisites to be the possession of 5 hides of land, a church, a kitchen, a bell house, a judicial seat at the burgh gate, and a distinct station in the king's hall. Sharon Turner ("History of the Anglo-Saxons") thinks that the superior thanes were those subsequently called barons, as the terms are synonymous in the laws of Henry I., and that the inferior thanes were those who after the conqueror's time were termed knights.

THANET, *Isle of*, an island of England, on the N. coast of Kent, separated from the mainland by branches of the river Stour called the Stour-wantsome, the Mele-stream, and the Nethergong-wantsome; extreme length 10 m., breadth 5 m.; area, 26,500 acres; pop. in 1851, 81,798. The island contains several towns, the most important of which are Ramsgate, Margate, and Broadstairs. The N. E. point of the island is called the North Foreland, and has a lighthouse on its extremity, the light of which is visible at the distance of 22 m. The surface, elevated and nearly level, is generally rich and fertile, and cultivated with great care.

In the time of the Romans the channel on the N. W. side, now almost completely closed, was from $1\frac{1}{2}$ to 4 m. wide, and was used as the main passage for vessels proceeding toward London; and it continued to be navigable for vessels of considerable size till the time of the Norman conquest. The island was then nearly circular, but it has been gradually washed away till it is now an irregular oval. This wasting away is still going on, and the average annual loss is estimated at 2 feet on the N. side, and 3 feet on the S. between Ramsgate and Pegwell bay.

THASOS, an island of the Grecian archipelago, belonging to Turkey, lying off the S. coast of Roumelia, about 80 m. N. N. E. from Mt. Athos, nearly circular in form; area, about 85 sq. m.; pop. 6,000. The centre of the island is occupied by Mt. Ipsario, a summit 3,428 feet above the level of the sea, and thickly covered with fir trees. The soil is not fertile, and the inhabitants, scattered in 12 small villages, do not produce grain enough for their own consumption. The vine was formerly cultivated, and the wine of Thasos was celebrated, but little or none is now produced. All trace of its ancient gold mines, which yielded a large revenue, has disappeared.—Thasos was an island of great importance in ancient times. It was settled by the Phœnicians, led by Thasos, the son of Agenor, who are said to have come thither in search of Europa 5 generations before the birth of the Grecian Hercules. In the latter part of the 8th century B. C. it was colonized by settlers from Paros, who in the course of 2 or 3 generations became a powerful colony, and obtained possessions and mines on the mainland as well as those on the island. The wealth of the Thasians excited the jealousy and covetousness of their neighbors. Darius (492 B. C.) commanded them to dismantle their fortifications and remove their ships to Abdera, and they did not dare to disobey. When Xerxes marched through Thrace on his way to Greece, the Thasians on account of their possessions on the mainland were compelled to provide for the Persian army as it marched through their territories, and their expenditure was 400 talents (\$460,000). After the defeat of the Persians Thasos became a member of the confederacy headed by the Athenians; but in 465, in consequence of disputes between the Thasians and Athenians, the latter sent Cimon with a large army against the island, which he subjugated and despoiled, after a siege of more than two years. Its subsequent history is one of almost constant conflict with Athens, to which it was nominally subject, until the time of the Roman wars, when it submitted to Philip V. of Macedonia; but after the battle of Cynoscephalæ (B. C. 197) it became a free state. After the capture of Constantinople by the Turks it fell into the hands of the Venetians. Some remains of its ancient city Thasos still exist.

THATCHER, BENJAMIN BUSSEY, an American author, born in Warren, Me., Oct. 8, 1809,

died in Boston, July 14, 1848. He was graduated at Bowdoin college in 1826, and studied law, but devoted himself to literature. In 1836 he visited England for his health, and spent two years there. He left several unpublished works, and numerous poems, essays, and fugitive pieces. His published works are: "Biography of North American Indians who have been distinguished as Orators, Statesmen, Warriors," &c. (2 vols. 18mo., New York, 1832); "Traits of the Boston Tea Party" (18mo., New York); "Traits of Indian Manners, Character," &c. (2 vols. 18mo., New York, 1835); "Tales of the American Revolution" (18mo., New York); and "Memoir of Phillis Wheatley" (18mo., Boston, 1834).

THAYER, SYLVANUS, an American officer of the engineer corps, born at Braintree, Mass., in 1785. He was educated at Dartmouth college, and at the U. S. military academy at West Point, where he was graduated in 1808 as 2d lieutenant of engineers. His first service was that of aiding in the construction of the fortifications in Boston harbor. In the war of 1812 he served on the Canadian frontier, and subsequently at Norfolk, Va., where he won the brevet of major. In 1815 he was sent by the government with Col. McRae to France and Belgium, to examine the fortifications in those countries. On his return in 1817 Major Thayer was appointed by President Monroe superintendent of the West Point military academy, where he remained till 1833, when he was appointed to construct the defences of Boston harbor. In 1838 he was made lieutenant-colonel, having already been colonel by brevet since 1833. From 1857 till 1859 he was temporary chief of the U. S. corps of military engineers. In Feb. 1862, he was placed on the retired list.

THEATINES, the name of a religious order in the Roman Catholic church, founded in 1524 by Gaetano di Thiene (died in 1547, canonized in 1669), Giovanni Pietro Caraffa, bishop of Theate (afterward pope under the name of Paul IV.), Bonifazio di Colle, and Paolo Consiglieri. After the first named of their founders, they were sometimes called Oajetans; their common name, Theatines, is derived from the episcopal see of the second of the founders. The founders received the papal approbation of their new institution in the very year of its foundation, 1524, and with it the privileges of the regular canons of Lateran and the right of electing a superior every third year. Their members took the three usual monastic vows, and their original object was to labor for a reformation of the clergy. From Italy they spread to Spain, Poland, France, and Germany, and some members of the order were sent as missionaries to Tartary, Georgia (in the Caucasus), and Circassia. Having gained a considerable extension, they were ordered by Pope Paul V. to choose, instead of a superior, a general, for 6 years; but later the general's term of office was limited to 3 years. At the end of the 18th century the order had disappeared in all countries except Italy, where in 1860

it had 9 houses left.—There were also two communities of Theatine nuns (one of them a congregation of hermits), both founded by Ursula Benincasa, the one in 1583, the other in 1610. Neither of them had ever more than two establishments, and at present both are extinct.

THEATRE (Gr. *θεατρον*, a seeing place), a building in which plays or dramas are represented. The first theatres of the Greeks, who were the founders of the drama in our sense of the word (see **DRAMA**), were exceedingly rude affairs. Thespis is said to have acted his plays in a wagon, and in the time of Æschylus the performances took place upon temporary wooden scaffolds, one of which having broken down during a representation in which Æschylus and Pratinas were rivals (500 B. C.), the Athenians were induced to build the great theatre of Dionysus (Bacchus), the Lenseion, the first permanent structure of the kind of stone. It was about 160 years in building, and in the mean time other theatres had been erected in many parts of Greece and Asia Minor. The discovery of the remains of the theatre of Bacchus at Athens by Prof. Strack, royal architect of Prussia (who is still, in May, 1862, prosecuting his excavations), proves the descriptions of it previously accepted to be very erroneous. The seats of the spectators, comprising the *θεατρον* proper, rose one above another in arcs of concentric circles, each row forming only about $\frac{1}{3}$ of a circumference, instead of $\frac{1}{2}$ as hitherto supposed. The space immediately in front of the spectators, corresponding nearly to the modern pit or parquette, was called the orchestra, and was appropriated to the chorus. It was floored with boards, and in the centre of it stood the *θυμელი* or altar of Dionysus, upon a raised platform which was sometimes occupied by the leader of the chorus, the police, the flute player, and the prompter; the two last were placed on the side next the stage, and concealed from the spectators by the altar. The stage was behind the orchestra and raised above it, and the chorus, whenever they had to take a part in the real action of the drama, ascended to it by steps. The back was closed by a wall called the *σκηνη* (Lat. *scena*); the space between the scena and the orchestra was known as the proscenium; and the part nearest the audience, where the actors stood when they spoke, was the *λογιον*. There was no scenery, properly so called, but the scena was architecturally decorated and made to represent as far as possible the locality in which the action was going on. It had an entrance in the centre called the royal door, through which the principal characters made their appearance, and doors on the right and left for the subordinate personages. The plays of Æschylus and Euripides, it is true, seem to require frequent changes of scene, but probably the changes were rather hinted at than actually made; they perhaps consisted merely in turning the *περιακτοι* (Lat. *versurae*) or "wings," which were prism-shaped frames moving on pivots at each side of the

proscenium. The whole stage was never concealed from the spectators; there is mention of a curtain, which instead of being drawn up was lowered through a crevice in the stage, but it covered only the background, or according to some authorities the wings. The machines for producing supernatural effects must have been numerous and elaborate, but are now imperfectly understood. They included the "Charonian steps," by which shades ascended from the lower world; the *μηχανη*, by which gods and heroes were represented passing through the air; and the *σελογεσιον*, an elevated place above the scena, where the deities appeared in full majesty. Neither the stage, the orchestra, nor the auditorium was roofed, but there were porticos running around the building, to which the people retreated in case of rain, and awnings were sometimes used to ward off the heat of the sun, for the performances always took place by daylight. The vast size of the ancient theatres, intended as they were to accommodate almost the entire population of a city at each performance, was their most serious defect. It being impossible for the human voice unaided to reach such a vast multitude, metallic vases were placed under the seats to serve as reflectors of sound, and the actors wore masks with metallic mouth-pieces to answer the purpose of speaking trumpets. Thus all expression both of voice and countenance was lost. The spectators were seated according to their rank. A price was charged for admission, at least until the performance was pretty far advanced; but from the time of Pericles the poorer class and subsequently all the citizens were admitted at the cost of the public treasury. Whether women were ever present has been much disputed; it seems almost certain, however, that they were allowed to witness tragedies. The actors were invariably males. The performances began early in the morning, and not unfrequently lasted 10 or 12 hours.—The Roman theatres were copied from those of the Italian Greeks. They were at first temporary structures of wood, which were sometimes extravagantly magnificent. One built by M. Æmilius Scaurus (58 B. C.) was capable of seating 80,000 people, and the scena was decorated with 8,000 statues and 360 columns in 3 stories, the lowest of white marble, the middle one of glass, and the uppermost of gilt wood. The first stone theatre was pulled down before it was finished at the instance of P. Scipio Nasica (155 B. C.), on the score of public morality. In the Roman theatre women performed in interludes and mimics, but not in regular dramas. The seats of the spectators and the orchestra did not form more than a semicircle, the diameter of which was identical with the front of the stage; and the orchestra, instead of being appropriated to the chorus, was occupied by the senators, foreign ambassadors, and other distinguished persons. There was nothing corresponding to the *θυμელი*, or altar, of Dionysus. The depth of the stage

was proportionally somewhat greater than in the Greek theatre, being in the latter about $\frac{1}{4}$ of the diameter of the orchestra, and in the Roman $\frac{1}{2}$. Thus, in the theatre of Dionysus at Athens the diameter of the orchestra (and consequently the width of the available part of the stage) was 72 feet, and the depth of the stage only a little more than 10 feet. A Roman stage of the same width would have been $17\frac{1}{2}$ feet deep. The following are some of the largest ancient theatres whose ruins are now known:

Location.	General diameter, feet.	Diameter of orchestra, feet.
Ephesus	680	240
Tralles	540	150
Rome (theatre of Marcellus) ..	517	173
Miletus	474	224
Sparta	458	217
Syracuse	440
Dramyssa	440	78
Aspendus	400	25 rows of seats
Cnidus	400
Phellus	400	width of scena, 150

—Between the decline of the ancient and the rise of the modern drama there is a long interval, in which the nearest approach to theatrical performances is found in miracle plays, mysteries, and interludes. These were given for the most part in convents, colleges, and churches, or in the halls of palaces and castles. The first theatres in France were built for miracle plays. As early as 1548, however, the confraternity of the Trinity had a theatre in Paris in which they were licensed by the parliament to perform only "profane pieces of a lawful and honest character." So late as 1561 the French had no scenery, and the performers remained on the stage during the whole representation. The first Italian theatre is said to have been erected at Florence in 1581, by Bernardo Buontalenti, but it was probably not public. About the same time Palladio made an attempt to revive the classical theatre in his celebrated *teatro Olimpico* at Vicenza, but with reduced proportions. It is of semi-elliptical form, with the stage on the longer axis of the ellipse, and the scena has the ancient permanent architectural background, with avenues seen through the openings in it, the apparent length of which is increased by artificial perspective. From 1618, when a theatre was built at Parma by Aleotti, the modern arrangement began to prevail. By narrowing the stage opportunity was given for the use of painted scenery, and by increasing its depth for the introduction of a variety of complicated machines and the production of spectacular pieces.—In England there were regular companies of players as early as the reign of Edward IV., long before there were regular play houses. Churches, universities, private houses, and the yards of inns served at first for their performances. Probably the first play house was the London "Theatre," built before 1576; the Curtain in Shoreditch, and the theatres in Blackfriars and Whitefriars, were built near the same time. In Shakespeare's day London

had 3 "private" and 4 "public" theatres, the difference between which is not clearly understood. His own plays were produced at the house in Blackfriars and at the Globe, both of which belonged to the same company, known as his majesty's servants. The Globe was a hexagonal wooden edifice, partly open at the top and partly thatched. In the middle was probably an uncovered court where the common people stood, and around 8 sides ran galleries or "scaffolds," under the lowest of which were enclosed boxes called "rooms." The prices of admission ranged from a penny or twopence to a shilling. The performance commenced at 8 o'clock; in the private theatres it took place by candle light. The stage at this period was strewn with rushes and concealed by curtains, which opened in the middle and drew backward and forward on an iron rod. In the background there was a balcony or upper stage, likewise curtained, from which parts of the dialogue were spoken, and at each side of this balcony there was a private box. In the private theatres the wits, critics, and other persons of consequence were furnished with seats on the stage. Movable scenery was first used in a regular drama on a public theatre by Davenant in 1662, though something of the sort had been arranged at Oxford by Inigo Jones as early as 1605, on the occasion of an entertainment given to James I. Shakespeare had no other scenery than tapestry hangings and curtains, but the use of stage machinery of a more or less elaborate nature is as old as the drama itself. Women first appeared upon the English stage about the period of the restoration.—The first theatre in America was opened at Williamsburg, Va., Sept. 5, 1752. Others followed at Annapolis, Md., and in Nassau street, New York (1758), Albany (1769), Baltimore (1778), Charleston, S. C. (1774), Newbern, N. C. (1788), and Boston (1792). The largest in the United States are now the opera houses of New York, New Orleans, Cincinnati, Boston, Philadelphia, and Brooklyn. Modern theatres, except those intended for opera, are now almost always small. The expenses are thus diminished, and all the audience are brought within easy seeing and hearing distance. It has been found by experiment that the human voice, moderately exerted, can be distinctly heard about 90 feet in front of the speaker, and 75 feet each side. In an opera house the dimensions may be vastly increased, as singing can be heard at a greater distance than speaking, and it is not requisite to bring the audience near enough to see the facial expression of the performers. The small acting theatres of New York have been considered the best of their kind in the world; and the opera house of the same city, though defective in its arrangement of seats, is one of the handsomest in existence. The best form for the auditorium is either three fourths of a circle, or a semicircle with divergent ends. The latter affords the best opportunities for seeing, but

involves either a disproportionate and inconvenient width of stage, or a considerable useless space on each side of the proscenium. Most American theatres differ from those of Europe in having no private boxes, except a few on and adjoining the proscenium, by which means a vast gain is effected in the capacity of the house; they are also generally better lighted. The following are some of the largest theatres in the world, with the number of spectators they are capable of accommodating:

St. Petersburg, Bolshoi theatre.....	5,000
New York, academy of music.....	4,700
Milan, La Scala.....	4,000
London, New Pavilion, Whitechapel.....	3,700
" Drury Lane.....	3,500
" her majesty's, Haymarket.....	3,500
" Italian opera, Covent Garden.....	3,000
Naples, San Carlo.....	3,000
Venice, La Fenice.....	3,000
Philadelphia, academy of music.....	2,850
Turin, theatre royal.....	2,500
Florence, La Pergola.....	2,500
Munich, royal theatre.....	2,500
Brooklyn, academy of music.....	2,200
Paris, Académie Impériale de musique.....	1,950
" Ambigu comique.....	1,900
" Porte St. Martin.....	1,900
" Théâtre Italien.....	1,700
" Théâtre Lyrique.....	1,700
" Odéon.....	1,650
" Opéra comique.....	1,500

—In China every little village has its theatre, and each great town has several. They have no scenery and no auditorium, the spectators remaining in the open air. There is of course no charge for admission, the expenses being defrayed sometimes by mandarins or other rich persons, but more frequently by associations formed for the purpose among the inhabitants of the neighborhood. The actors are invariably strollers. In Japan the histrionic art has made more progress; the stage is decorated with scenery, and the audience are furnished with seats. In neither country are women allowed to perform.

THEBES (called No or No-Ammon by the Hebrews, and Diospolis the Great by the later Greeks and the Romans), the capital of Upper Egypt, and for a long time of the whole country, reputed in antiquity the oldest city of the world. It stood near the centre of the Thebaid, extending on both sides of the Nile to the mountain chains which enclose the valley. The city, according to Strabo, covered the entire plain, an area above 5 m. in length and 8 m. in breadth, at least equal in extent to the site of ancient Rome or modern Paris. Diodorus estimated its circuit at 140 stadia or about 17 n., and Sir Gardner Wilkinson infers from its ruins that its length was 5½ m. and its breadth 1 m. The annual depositions of the Nile have permanently raised the soil, and buried the base of every monument; the layers around me of the colossal sphinxes are found by excavation to make a depth of 18 feet above the rubbish which occurs universally as the foundation of ancient Theban buildings. From some chronological inscriptions the rate of deposition appears to be 5 inches in every 100 years; so that, assuming this rate to have been

uniform, the substructure of the sphinx would have been laid nearly 2,500 years before the Christian era. This calculation, until further investigation, cannot be confidently received.—The monarchs of Thebes expelled the shepherd kings from Memphis and Lower Egypt about 1600 B. C., and made their city the capital of the whole country during several centuries. Amenophis I., the first king of the 18th dynasty, carried his arms into Syria and Ethiopia; Thothmes I. founded some of the most magnificent Theban edifices; Thothmes III. made his kingdom unrivalled in arts and in arms, and adorned all the cities of the Thebaid with architectural monuments; and Amenophis III. extended the Theban supremacy, and began the structures at Luxor. Rhamses I., Sethos, and Rhamses II., of the 19th dynasty (founded about 1824 B. C.), represent, according to Wilkinson, the Augustan age of Egypt, when its sway was the widest, and its most superb monuments were erected. The decline of Thebes began under the 21st dynasty; there was an Ethiopian revolt; Lower Egypt gradually resumed its preëminence, but with diminished power during the rise successively of the Assyrian and Persian empires; and when Cambyzes conquered Egypt (525 B. C.), the upper capital fell without a struggle, and ceased from that time to be a metropolitan city. The greatness of Thebes was known to Homer, who speaks of its 100 gates and 20,000 war chariots; Diodorus was informed that Sesostris (Rhamses II., according to Wilkinson) took the field with 600,000 infantry, 24,000 cavalry, and 27,000 chariots; but after its destruction by Ptolemy Lathyrus (86 B. C.), it lost all its political and commercial importance, though it remained the sacerdotal capital of the worshippers of Ammon. The lucrative trade which had contributed to its prosperity had found new channels after the foundation of Alexandria; and as a Macedonian and Roman prefecture it took little part in the affairs of Egypt. It was desolated successively by Christians of the Thebaid, in their zeal against idolatrous monuments, by barbarians from Arabia and Nubia, and by the Saracens; after whose invasion its name scarcely occurs for many centuries.—The ruins of Thebes, which are among the most magnificent in the world, are found at the modern villages of Luxor and Karnak on the eastern bank of the Nile, and Goorneh and Medinet-Abou on the western. The eastern quarter of the ancient city contained the mass of the population, while the western side was covered with temples and palaces and their avenues of sphinxes, and with the rock-hewn tombs of the kings. The principal structures at Goorneh are the palace temples Menephtueum and Remeseum. The former, approached by an avenue 128 feet in length, has pillars in the oldest style of Egyptian architecture and remarkable bas-reliefs. The latter, the Memnonium of Strabo, which for symmetry of architecture and elegance of sculpture may vie with any other

Egyptian monument, occupies a series of terraces communicating with each other by flights of steps. Its entrance is flanked by two pyramidal towers; its first court has a double avenue of columns on either side, and in the area a pedestal on which was a syenite sitting colossus of Rhameses; its second court has walls covered with sculptures representing the wars of Rhameses III., and Osiride pillars which are doubtless the monolithical figures of 16 cubits high described by Diodorus; the third stairway, from the foot of which Belzoni took the head of a royal statue of red granite, now in the British museum and known as the young Memnon, conducts to a hall used for public assemblies, with columns and walls covered with civil and religious sculptures; and beyond the hall extended 9 smaller apartments, two of which remain, supported by columns, one of them being the sacred library or "dispensary of the mind" mentioned by Diodorus. Among the other monuments in this vicinity are two colossal statues, 60 feet in height, the wonder of the ancients, one of them known as the vocal Memnon. (See MEMNON.) The village of Medinet-Abou stands upon a lofty mound formed by the ruins of the most splendid temple palace in western Thebes, the Thothmesium, connected with the palace of Rhameses by a dromos 265 feet in length. The sculptures in the latter are of singular interest, being the only examples that have been found of the decoration of the private apartments of an Egyptian palace. The whole sweep of the Libyan hills, for the space of 5 miles and to the height of 300 feet from Goornah to Medinet-Abou, is full of sepulchres, excavated in the native calcareous rock. This was the necropolis of the whole city, no tombs existing on the eastern side. The mummies are laid in rows by the side of or tiers above each other, but never stand erect. The tombs of the lower classes are unsculptured, but abound in mummies of sacred animals. The royal sepulchres are in the valley of Bab-el-Melook, the most spacious and highly adorned belonging to those monarchs who enjoyed a long reign. Here repose the Theban Pharaohs from the 18th to the 21st dynasty, but only 8 complete catacombs have been discovered. The monuments, as also those in the separate burial place allotted to the queens, are chiefly interesting from their hieroglyphics.—Still more remarkable are the ruins on the eastern bank of the river, in the villages of Luxor and Karnak. At Luxor the most striking monuments were two beautiful obelisks of red granite, covered with a profusion of hieroglyphics, one of which has been removed to the Place de la Concorde at Paris. Behind them are two sitting statues of Rhameses, one 39 feet high, but now covered to the breast with accumulations of earth and sand. Two courts and a series of apartments, connected and surrounded by colonnades and porticos, extend beyond. The road from Luxor to Karnak lies through fields of *half* grass, though they were

once united by an avenue of andro-sphinxes. The great palace temple of Karnak stands within a circuit wall of brick 1,800 feet long and somewhat less broad. It was approached by an avenue of crio-sphinxes, of which only fragments remain. Between the end of the dromos and the main body of the building, 5 lofty pylones and 4 spacious courts intervene. In the first court were two obelisks of Thothmes I., one of which still remains; in the second court is another obelisk, the loftiest known except that of St. John Lateran at Rome; and in one of the chambers are the sculptures which compose the Karnak tablet, one of the most important records of Egyptian chronology. The dimensions of the great hall are 80 feet in height, 329 in length, and 179 in breadth; the roof is supported by a central avenue of 13 massive columns, 66 feet high and 12 feet in diameter, together with 122 columns of less gigantic dimensions. These vast courts, halls, and esplanades were reared by kings of the 18th and succeeding dynasties for purposes partly religious and partly secular. The sacred calendar abounded in days for periodical meetings; the troops were reviewed and the apportionment of the spoils of victory made in the courts of royal palaces, which also served occasionally for the administration of justice and for the encampment of the army. The ruins of Thebes hold a foremost place in the researches and speculations of Egyptologists.

THEBES (in the classical writers *Thebe*; modern Gr. *Thèva*), in Greek antiquity, the chief city of Boeotia, built on and around a hill between the streams of Ismenus on the east and Dirce on the west. The citadel occupied the height, and the greater part of the town stood in the valleys. Of its ancient buildings, monuments, and walls, there remain only a few scattered fragments, and its topography is entirely uncertain. It is impossible to harmonize the ancient writers as to the position or even the names of its 7 gates. Thebes was equally illustrious in the mythical and the historical ages of Greece. It was the birthplace of the divinities Bacchus and Hercules, of the seer Thersias, the musician Amphion, the poet Pindar, and the warriors Pelopidas and Epaminondas; its two sieges and the fortunes of its royal houses were favorite subjects of tragedy; and it was for a time the ruling city of Greece. Tradition ascribed to Cadmus the foundation of the citadel, which was hence called Cadmea. From the 5 Sparti, the survivors of the progeny of the dragon's teeth, were descended the noblest Theban families. The expulsion of Œdipus, and the successive sieges by the "Seven against Thebes" and by the Epigoni, were the principal events before the Cadmeans were driven out by the Boeotians, a tribe from Thessaly. This occurred about 60 years after the Trojan war, according to Thucydides. The legislation of Philolaus, in the 8th century B. C., gave it an oligarchical instead of monarchical form of government, and made it the head of the con-

federacy of Boeotian towns. The first entirely certain event in its history is the revolt of one of these towns, Plataea (519 or 510 B. C.), which applied to Athens for protection. A war ensued between the Thebans and Athenians, in which the latter were successful, and which initiated lasting enmity between the two states. Thebes lost credit by abandoning the cause of Greece in the Persian war, and fighting against the Athenians at Plataea (479). The victorious Greeks appeared before its walls, and compelled the inhabitants to put their "Medizing" leaders to death. An Athenian invasion supplanted its oligarchy by a democratic government in 456, but the former was restored in 447. During the Peloponnesian war the Thebans were more anti-Athenian than even the Spartans, but joined the coalition against the latter in 395, and were the only portion of the allied army which was not routed by them at Coronea. The peace of Antalcidas, negotiated by Sparta (387), deprived them of their supremacy over the other Boeotian towns, and in 383 a blow was struck at their independence by the treacherous seizure of their citadel. They continued in the hands of the Spartan party for 8 years, when Pelopidas and others succeeded in expelling the garrison. In the hostilities which followed they recovered Boeotia, invaded Phocis, and triumphed over the Spartans at Tegyra (375). The decisive victory of Leuctra (371) gave to them the hegemony of Greece, and Epaminondas invaded Peloponnesus, and established there the Arcadian confederation and the state of Messenia as political powers antagonistic to Sparta. But they in vain sought to establish their supremacy by a general treaty, and lost it after the death of Epaminondas at Mantinea (362). Athens, long jealous of Thebes, was now able to resist it, and succeeded in wresting Euboea from it (358). Thebes was soon after supported by Philip of Macedon against both Athens and Sparta in the Phocian war, and continued in alliance with him till he seized Elatea (339), when the eloquence of Demosthenes induced the Thebans to unite with the Athenians against his dangerous projects. They sent an army to the battle of Chaeronea (338), in which their sacred bands cut to pieces in the ranks, and after which they opened their gates to a Macedonian garrison. The leading citizens were put to death or banished, but the exiles returned after Philip's death, besieged the garrison, and invited the other Greek states to declare their independence. The rapid advance of Alexander defeated their attempt (335). The city was razed to the ground, the temples and the house of Pindar alone being spared; the citadel was again held by a Macedonian garrison; the territory was divided among the allies; and the inhabitants were sold into slavery. Thebes was without inhabitants for the next 60 years, and, though restored by Cassander, never became again an independent state. In the time of Strabo it had dwindled down to

the condition of a village, in which it has since remained.

THEFT. See LARCENY.

THEINE. See CAFFEINE, and TEA.

THEINER, AUGUSTIN, a German theologian and priest of the Oratory, born in Breslau, April 11, 1804. He studied at the universities of Breslau and Halle, at first theology and afterward philosophy and law. While studying he fully shared the views of his brother, Johann Anton, on church reform, and assisted him in the publication of his extensive work on celibacy. An essay on the papal decretals procured for him from the university of Halle the degree of doctor of laws, and from the Prussian government a stipend for a scientific journey to Vienna, London, and Paris. A residence in a college of the Jesuits at Rome completely changed his theological views, and he became from an extreme Gallican one of the most uncompromising advocates of the papal prerogatives. He has ever since remained in Rome, where he was appointed in 1851 prefect of the secret archives of the Vatican. His writings, mostly on church history and church law, are very numerous, and many of them contain valuable documents, which he was for the first time permitted to publish from the papal archives. Among the more important of his works are a "History of Theological Seminaries" (Mentz, 1835); a "History of the Efforts of the Holy See to cause a Return of the Nations of Northern Europe to the Roman Church" (vol. i., Augsburg, 1837); a "History of the Return of the Houses of Brunswick and Saxony to the Roman Catholic Church" (Einsiedeln, 1848), &c. Against Oréteineau-Joly, who had censured Clement XIV. for having suppressed the order of the Jesuits, he wrote, in vindication of the pope, the "History of the Pontificate of Clement XIV." (2 vols., Leipsic, 1858). He undertook to continue the church history of Baronius, and published the first 8 volumes at Rome in 1858. A collection of important documents relating to the church history of Hungary, mostly taken from the Vatican archives, was published by him in 1859 (2 vols.); and similar collections respecting Poland and Lithuania (2 vols.) in 1860 and 1861, and respecting the church history of France from 1790 to 1800, in 1858 (2 vols., Paris).—**JOHANN ANTON**, a German theologian, elder brother of the preceding, born in Breslau, Dec. 15, 1799, died there, May 15, 1860. He studied Roman Catholic theology at the university of his native town, and was appointed there in 1824 professor of exegetical theology and of canonical law. He showed himself from the beginning a zealous advocate of Gallican principles, and took an eager part in movements among the clergy of Silesia for their practical introduction. Assisted by his brother Augustin, he published in 1826 an extensive work on the history of celibacy (*Die Einführung der erzwungenen Ehelosigkeit*, Altenburg, 1828; new ed., 1845), which at the time of its

publication made a deep sensation in Germany, and is regarded as the most complete work on the subject. He resigned his chair in 1830, and held a pastoral charge until 1845, when he joined the German Catholics, publishing in vindication of this step *Die reformatorischen Bestrebungen in der katholischen Kirche* (Altenburg, 1845). But he soon disconnected himself from the movement, as its principal leaders, in his opinion, went too far, and joined the Protestant church. He afterward received an appointment in the library of the university of Breslau. Beside the works already mentioned, he wrote a commentary on the minor prophets, forming part of the Bible work of Dereser, and *Das Seligkeits Dogma der katholischen Kirche* (Breslau, 1847).

THEISS (anc. *Tibiscus*; Hun. *Tisza*), a river of Europe, which drains all eastern Hungary and the greater part of Transylvania. It is formed by the union of the Black and White Theiss about 20 m. E. N. E. from Szigeth, in the county of Mármaros, flows first westward to Tokay, thence S. W. to Szolnok, when it turns S. and enters the Danube near Titel, in the Military Frontier land, 22 m. E. S. E. from Peterwardein. Its length is about 500 m., for most of which it is navigable. Its principal tributaries are the Szamos, the Bodrog, Zagyva, Körös, Maros, and Bega. The chief commerce of the river consists in the conveyance of salt, timber, and agricultural produce.

THELWALL, JOHN, an English author and elocutionist, born in London, July 27, 1764, died in Bath, Feb. 17, 1834. He was originally intended for an artist, but subsequently studied law, which however he abandoned in his 22d year for the profession of literature. In 1787 he published poems in 2 volumes, which brought him into notice; and embracing liberal opinions, he became a member of the "Corresponding Society." Taking a prominent part in the political agitation of the times, he was prosecuted for high treason along with John Horne Tooke and Thomas Hardy, and after a trial of 5 days was acquitted. He afterward lectured for a number of years on political subjects, and in 1801 began to act as tutor of elocution, upon which he contributed several papers to the "Medical and Physical Journal" and to the "Monthly Magazine." He also published "Poems written in the Tower and in the Newgate," "The Tribune" (3 vols.); "Political Miscellanies;" "A Letter to Mr. Oline on Stammering;" "The Peripatetic" (3 vols.); and a novel called "The Daughter of Adoption."

THEMIS, in the Greek mythology, a daughter of Uranus and Gæa, married to Zeus. She dwelt in Olympus, and convened the assembly of the gods. She is represented in Homer as the personification of the order of things established by law, custom, and equity. At Thebes she had a sanctuary in common with Zeus Agoræus, and at Olympia in common with the Horæ, her daughters. Temples were also dedicated to her at Athens, at Tanagra, and at Trœzene.

THEMISTOCLES, an Athenian statesman and general, born about 514 B. C., died in Magnesia, Asia Minor, about 449. He was in early life so remarkable for his ambitious character that his master said to him: "My boy, you will not be any thing little, but certainly something great, good or bad." He was present at the battle of Marathon in 490 B. C., and may have been general of his tribe on that occasion. After the disgrace of Miltiades, Aristides and Themistocles became the chief men of Athens, and the rivalry between the two was so bitter that the former is reported to have remarked: "If the Athenians were wise, they would cast both of us into the *barathrum*." The contention, after being carried on 3 or 4 years, resulted in 483 in an appeal to a vote of ostracism, and Aristides went into exile. From this time Themistocles was the great political leader in Athens, and his active genius saw at once the steps necessary to be taken to save the city from the threatened revenge of the Persian king, who had been making vast preparations for the conquest of Greece. He persuaded the Athenians to build 200 ships with the produce of the silver mines of Laurium, instead of distributing it among the citizens; and he endeavored in various ways to make Athens a great naval power. The open bay of Phalerum was given up as a harbor, and the new harbor of Piræus was begun to be formed and fortified during the year when he was either archon or general. In the beginning of 480, as the force of Xerxes was on the point of passing the Hellespont, 10,000 heavy-armed Greeks, under the command of the Spartan Euseñetus and Themistocles, occupied the defile of Tempe; but finding that troops could be landed in their rear, and that there was another entrance into Thessaly through Macedonia, they retreated to their ships. All northern Greece was in consequence left defenceless, and either joined or submitted to the invaders. Themistocles now commanded the Athenian portion of the fleet which was stationed at Artemisium, under the Spartan Eurybiades. When the vast number of Persian ships was discovered, Eurybiades was disposed to draw back to southern Greece; but the Eubœans gave 30 talents to Themistocles, with which he induced the Spartan commander, and also the Corinthian Adimantus, to remain and defend Eubœa. In the ensuing battle, fought on the same days with the engagement at Thermopylæ, the Greeks had the advantage; but that pass having fallen into the hands of the enemy, and the Athenian ships being much crippled, it was determined to retire. Themistocles first, however, caused to be cut on the rocks at various points an address to the Ionians in the Persian fleet, entreating them either to desert or to fight backwardly against men of their own race. Athens, at the instance of Themistocles, was abandoned by its inhabitants, and its defence, in accordance with a Delphic response probably dictated by him, intrusted to

the "wooden walls" of the fleet; and the whole naval force of Greece was gathered together at Salamis under Eurybiades. Of the 378 ships, beside penteconters, comprising the fleet, the Athenians furnished 180. It was in consequence of the threat of Themistocles that the Athenian contingent would sail away to Siris in Italy, that it was determined to give battle; and when a fresh council had resolved to sail to the Peloponnesus, he frustrated their plan by sending a slave to the Persian commander with a message that the Greeks were meditating a flight, and could easily be cut off. The Persian fleet was consequently moved down in the night so as to enclose the Greeks, and there was no choice left for the latter but to fight. (See *GREECE*, vol. viii. p. 448.) After the great victory there gained, Themistocles and the Athenians were desirous of pushing on to the Hellespont and destroying the bridge of boats in order to prevent the retreat of Xerxes; but to this the other confederates refused to agree, and the plan was abandoned. Themistocles, however, according to the testimony of Herodotus, privately sent word to the king that he had restrained the Greeks from pursuing his ships and breaking up his bridges over the Hellespont; and this he did in order to induce Xerxes to return, and that he might have a safe retreat in case any mischance should in the future befall him at Athens. He now employed his fleet in levying contributions from the Greek islands which had adhered to the Persians, and by this means gained considerable money for himself, without the knowledge of the other generals. After the division of the booty gained at Salamis, the Greeks sailed to the isthmus, where he was deprived of the first prize for skill and wisdom by each of the commanders voting for himself, but had a large majority of votes for the second prize. The envy of the leaders prevented any decision being made, but Themistocles was regarded as the wisest man in Greece, and the whole country was filled with his fame. He went to Sparta, and was there received with unprecedented honors; and though the Lacedæmonians gave to Eurybiades the crown of valor, they gave to Themistocles the crown of wisdom. When the Athenians returned to rebuild their ruined city, and to reconstruct their fortifications on an enlarged scale, Sparta from jealousy, but under a friendly guise, opposed and might have thwarted the project of re-fortifying; but Themistocles was sent there as ambassador, and contrived to deceive the Spartans until the walls were far enough advanced to be in a state of defence. Athens was now secure against external enemies, and Themistocles was more than ever desirous of making her a great maritime power. The work on the Piræus was resumed on a far grander scale, and the plan of the fortifications was such as to render them impregnable. To this costly and difficult work he encouraged the people by telling them that the Piræus was of more value to them than Athens itself,

and that in case their city was taken they might retire behind these walls and on the sea defend themselves against the maritime power of the world. He also persuaded the Athenians to build every year 20 new triremes. The story told by Plutarch of his project for burning all the Grecian ships except the Athenian, so that no city but Athens might have a naval force, which was defeated by the justice of Aristides, is unquestionably a pure fabrication. After the fortification of the Piræus his political ascendancy declined, in consequence of his duplicity, his unprincipled love of money, and especially his acts in regard to the insular allies. His opponents in Athens were headed by Cimon the son of Miltiades, and by Alcmaeon. He was tried and acquitted on a charge of treasonable intercourse with the Persians, but about 471 was ostracized and went into exile to Argos. While he was there the treason of Pausanias was discovered, and among his letters were found proofs of the privacy of Themistocles. The Lacedæmonians sent to Athens to prefer against him a charge of treason, and joint envoys from Athens and Sparta were despatched to Argos to arrest him. Having notice of their coming he fled, and after twice narrowly escaping capture reached Susa, where he addressed to Artaxerxes, the son of Xerxes, a letter claiming protection on the score of his services to his father after the battle of Salamis, and asking permission to wait a year and then to come before him in person to explain his views. His request was granted, and he himself treated with honor. At the end of a year, having mastered the Persian language, he entered into personal communication with the king; and no Greek, says Thucydides, had ever before attained such a commanding influence and position at the Persian court. He excited Artaxerxes with plans for the subjugation of Greece, and was presented by him with a Persian wife and with large presents. After visiting various parts of Asia, he lived at Magnesia on the Mæander, and received his maintenance from the revenues of that and two neighboring cities. Some of his property at Athens was secretly sent him by his friends, but the bulk of it, amounting to 80 or 100 talents, was confiscated. He is said to have poisoned himself because he knew his promises to the Persian king could not be fulfilled. "Themistocles," says Thucydides, "was the strongest example of the power of natural talent, and in this respect is particularly worthy of admiration; for by his natural understanding, without any education originally to form it, or afterward to strengthen it, he had the best judgment in actual circumstances, and he formed his judgment with the least deliberation; and as to future events, he made in general the best conjectures; whatever he took in hand, he was also able to expound; and on matters where he had no experience, he was not unable to form a competent judgment; and both of the better and the worse, while it

was still in uncertainty, he had a most excellent foresight; and to express all in brief, by the force of his natural capacity and the quickness of his determination, he was the most efficient of all men in promptly deciding what was to be done." His life was written by Nepos and by Plutarch.

THÉNARD, LOUIS JACQUES, baron, a French chemist, born at La Louptière, Aube, May 4, 1777, died in Paris, June 21, 1857. The son of a poor farmer, he early repaired to Paris, and applied himself to chemistry under Fourcroy with such success as to be appointed, when scarcely 20 years old, assistant professor of that science in the polytechnic school, and afterward became professor there, at the college of France, and at the Sorbonne. He succeeded Fourcroy as member of the academy of sciences in 1810, and subsequently became a member of nearly all the learned societies of Europe. His clearness of exposition and elegance of style, enhanced by scientific fervor, made his lectures very popular. (See CHEMISTRY, vol. v. p. 41.) Charles X. on his accession to the throne made him a baron, and in 1827 he was elected to the chamber of deputies. Under Louis Philippe he became a member of the council of public instruction, was created a peer in 1833, grand officer of the legion of honor in 1842, and soon afterward chancellor of the university. He was for many years president of the society for the encouragement of national industry; and near the close of his life he founded a "Society for the Succor of Friends of Science," for the benefit of inventors impoverished by useful researches, and contributed 20,000 francs to its funds. His most popular work, *Traité élémentaire de chimie théorique et pratique* (4 vols. 8vo., 1818-'16; 7th ed., 5 vols., 1836), has been translated into several European languages. He was a constant contributor to the *Annales de chimie*, *Annales de physique et de chimie*, and the *Mémoires* of the society of Arcueil and the academy of sciences.

THEOBALD, Lewis, an English author, born in Sittingbourne, Kent, died in Sept. 1774. He was the son of an attorney, and was bred to his father's business, but early abandoned it for literature. His first production was a now forgotten tragedy called "Electra," which appeared in 1741; and in 1717 he contributed to *Mist's* "Weekly Journal" a number of papers under the title of "The Censor," and by his criticisms provoked attacks from other writers, one of whom was Dennis. He is now remembered chiefly for having been the original hero of the "Dunciad," though in the later editions he was displaced to make way for Cibber. This position he owed to having pointed out the errors in Pope's edition of Shakespeare in a pamphlet entitled "Shakespeare Restored; or, a Specimen of the many Errors as well committed as unamended by Mr. Pope in his Edition of this Poet, designed not only to correct the said Edition, but to restore the true Reading of Shakespeare in all the Editions ever yet

published" (4to., London, 1736). For the attack upon him in the "Dunciad" he brought out an edition of Shakespeare's works (7 vols. 8vo., London, 1738), which entirely destroyed the reputation of Pope's edition. Theobald wrote or translated 20 plays, now all forgotten, and also brought on the stage a play entitled "The Double Falsehood, or the Distrest Lovers," the greater part of which he asserted was composed by Shakespeare. Dr. Farmer maintained that it was the work of Shirley, but modern critics generally agree that there is in it very little either of Shakespeare or Shirley, and very much of Theobald. He was also author of a life of Walter Raleigh, and at the time of his death was engaged upon an edition of Beaumont and Fletcher.

THEOCRITUS, a Greek pastoral poet, a native of Syracuse, who flourished about 270 B. C. He went to Alexandria, and secured the favor of Ptolemy Philadelphus, but returned to Syracuse during the reign of Hiero II. Nothing else is known of his life. He wrote in a mixed dialect in which the Doric predominated, and was the creator of pastoral poetry as a department of literature. There are extant 30 poems, called by the general name of "Idyls," which are attributed to him, although some are doubtless spurious. Beside these, 5 lines from a poem called "Berenice," and 23 epigrams in the Greek anthology, are ascribed to his pen. Theocritus has had several imitators, of whom the greatest was Virgil, numerous commentators, and innumerable editors. The first edition was published without name of place or date, but probably at Milan about 1498; the latest is that of J. Meineke (Berlin, 1856). The "Idyls" have been several times translated into English.

THEODOLITE (Gr. *θεω*, see, *δολος*, manifest, and *τρος*, circumference), an instrument used in surveying for measuring angles, both horizontal and vertical. When this instrument was invented is uncertain, but an act of the general court of Massachusetts of 1735 gives to Roland Houghton, a merchant of Boston, exclusive privileges for 7 years, for making and selling an instrument for surveying land of his invention called the new theodolite, by which, as declared in the act, "land could be surveyed with greater ease and despatch than by any surveying instrument heretofore projected or made within this province." It came into use soon after, and took the place in important surveys of the quadrant and repeating circle. It consists of a circular plate of metal so attached upon the head of a tripod or other support as to be readily brought to a horizontal position by thumb screws, according to the indications of the attached levels. Its outer circumference is divided into degrees and parts of degrees. A vertical axis passing through its centre supports a second plate nearly touching the lower one, and easily moved in either direction upon its axis. On opposite sides of the upper disk a portion of the

edge is chamfered away, and upon the bevelled surface, forming a continuous slope with that of the edge of the lower plate, are marked the divisions of the vernier scale by which the degrees may be read off to minutes. Very large theodolites have 3 verniers 120° apart, the average readings of which reduce the liability of error. The upper plate carries upright standards firmly fixed to it, upon which is supported a telescope directed across its horizontal axis, so that it may be turned up and down in a vertical plane. A graduated arc of which this axis is the centre passes below the telescope between the standards, and serves to measure the degree of elevation or depression of the telescope. A long spirit level attached to the telescope itself affords a further check upon the accuracy of the levelling when the telescope is taken out of the Y's that support it and reversed. The vernier for the vertical arc is attached to the compass box, which occupies a position directly over the centre of the upper plate. The instrument is furnished with screws by which the plates are clamped, and also tangent screws for giving slight motions in a horizontal or vertical direction. When the telescope is directed to any object, the readings of the verniers are taken; the lower plate is then clamped, and the telescope is turned with the upper plate to any other object, and the horizontal angle between the two is thus directly obtained, the telescope being elevated or depressed as may be necessary. The difference of elevation may at the same time be noticed upon the vertical arc if desired, or the angle which either point makes from the horizontal line. The instrument may thus be used for levelling or for determining heights by triangulation. The theodolite differs from the transit in the limited range of the telescope of the former upon its horizontal axis, while the transit can be turned completely over so as to sight in either direction. The latter is a much more convenient and exact method of prolonging a straight line than by turning the telescope of the theodolite half round or reversing it in its Y's. The transit is very generally used in the United States, especially by railroad surveyors, instead of a theodolite; and to distinguish it from the astronomical transit instrument it is sometimes called engineer's transit, or railroad transit. It is sometimes furnished with a vertical circle for measuring vertical angles, and may then be called a transit theodolite. Theodolites of large size have been employed upon important trigonometrical surveys. Ramsden's great theodolite, completed in 1787 and used upon the surveys for connecting the observatories of Greenwich and Paris, had a circle of 8 feet diameter; other instruments of the same size have been used by the British government in England, Ireland, and India. The principal theodolites used upon the United States coast survey are very perfect instruments constructed by Gambey of Paris, the largest with a circle of 30 inches diameter and others of 10 inches.

(See COAST SURVEY, vol. v. p. 396.) Theodolites in ordinary use have circles 5 inches in diameter.—For full descriptions of the construction and use of theodolites, see Heather's "Treatise on Mathematical Instruments," in Weale's "Rudimentary Series," and "Gillespie's Treatise on Land Surveying" (New York). The report of the superintendent of the coast survey for the year 1856 contains full instructions, by assistant J. E. Hilgard, in the method of testing a repeating theodolite.

THEODORA. See JUSTINIAN.

THEODORET (THEODORETUS), a father of the Greek church, and one of the chief representatives of the theological school of Antioch, born at Antioch in 386 or 393, died in 457 or 458. He was the scion of a noble family, went after the death of his parents into a cloister, became in 420 bishop of Cyrrhus on the Euphrates in Syria, and reunited many members of the sects with the Catholic church. He declared against the Nestorians, and at the council of Chalcedon, in 451, subscribed the condemnatory decree against Nestorius. He was one of the best exegetical writers of the ancient school (see Richter, *De Theodoro Epistolarum Paulinarum Interprete*, Leipsic, 1822), and beside wrote homilies, of which those on Divine Providence are especially valuable; a history of the Christian church from 324 to 429; an epitome of heretical fables, the lives of 80 hermits, and 180 letters. Collective editions of his works have been edited by Sirmond (4 vols., Paris, 1642), and by J. L. Schulze and Nösselt (10 vols., Halle, 1769-'74). A translation of his "Ecclesiastical History" was published in Bohn's "Ecclesiastical Library" (London, 1854).

THEODORIC (Ger. *Dietrich*), surnamed THE GREAT, king of the Ostrogoths, born in Pannonia in 455, died in 526. The son of Theodemir, one of the chiefs of the Ostrogoths settled on the banks of the Danube, he was when 8 years old sent as a hostage to the court of Constantinople, where he was carefully educated in all martial arts and exercises, but utterly neglected literary culture. He was restored to his father at the age of 18, and, after greatly distinguishing himself in war, succeeded him as sole king of the Ostrogoths in 475. The southern part of Pannonia and Dacia had previously been ceded to them by the emperor Zeno the Isaurian, of whom Theodoric was for some years a faithful ally; but the emperor breaking his promises, war broke out between them, and Theodoric ravaged the Byzantine territories till Zeno in 488 appeased him by conferring upon him large gifts and many honors, even naming him consul in 484. The war was however renewed in 487, and Theodoric marched upon Constantinople; and to get rid of him Zeno proposed to him the invasion of Italy, then ruled by the usurper Odoacer. He consequently in 488 marched toward the peninsula at the head of his whole people, amounting to about 200,000, with a large num-

bar of wagons conveying their most precious effects and their store of provisions. He first met in the Alpine passes and routed an army of Gepids and Sarmatians, then defeated Odoacer himself on the banks of the Sontius (Isongo), Aug. 28, 489. After two other victories, one near Verona, the other on the banks of the Adda, he shut his opponent within the walls of Ravenna, and after a siege of more than 8 years received his capitulation in 493, apparently consenting to share the kingdom of Italy with him; but Theodoric soon after had his rival assassinated at a solemn banquet, and firmly established his power over the whole peninsula. He distributed one third of the lands to his soldiers in military tenures, but preserved as far as possible the administrative organization of the Roman empire. Under his fostering care Italy became prosperous again; agriculture and industry revived; literature and the fine arts flourished; internal improvements went on, and new monuments were erected. His foreign policy proved equally successful; through well devised alliances, he controlled nearly all the barbarians that had settled in western Europe. He checked the triumphant progress of Clovis after the victory of Vouillé in 507, protected the Visigoths, and secured for himself the possession of Provence. His latter years were embittered by religious troubles; the Arians, to which sect he belonged, being persecuted in the East, he retaliated against the Catholics of Italy; this brought on a conspiracy, in which the philosopher Boëthius, a great favorite with him, and the venerable Symmachus were apparently involved, and in a moment of passion he ordered them to be put to death. Their innocence being afterward demonstrated, remorse preyed upon his mind and hastened his death. He is the Dietrich of Bern of the *Nibelungen-Lied*.

THEODORUS, king of Abyssinia, born about 1820. He is the son of a petty official in the province of Kuara in West Abyssinia, and his real name is Kassai. In a school at Gondar he learned to read and write, and afterward entered the army of the governor of Dembea, and served in the campaigns against the Turks. The governor recommended Kassai to his master Ras Ali, who gave him his daughter in marriage, and an official station under his mother Waisoro Meunen, to whom the province of Dembea belonged. With her Kassai soon quarrelled, defeated her army, took her prisoner, and released her only on condition of surrendering Dembea. Ras Ali, unable to avenge his mother, made over the province to Buru Goshu, the governor of Gojam, who in 1850 forced Kassai to seek refuge in the mountains of his native Kuara. Here he collected a band of followers, and, in Nov. 1852, unexpectedly reentered Dembea, killed Buru Goshu himself, and defeated his army near Lake Tzana. In 1853 he became involved in a war with his father-in-law, who called in to his aid Ubye, the powerful ruler of Tigré, but was de-

feated and obliged to fly to the Gallas. Before attacking Ubye, Kassai formed an alliance with the abuna or primate, Abba Salama, who agreed to come to Gondar on condition that the Roman Catholic priests were expelled. By the defeat of Ras Ali, Kassai had become prince of Amhara, and he summoned Ubye to pay tribute; and on the refusal of that ruler a war ensued, in which the lord of Tigré lost his kingdom and his liberty. Kassai now assumed the title of king of the kings of Ethiopia, and the name of Theodorus, doubtless in reference to the old tradition that a king of the name of Theodorus should arise, who would make Abyssinia great and prosperous, and destroy the two chief Mohammedan cities in Arabia, Mecca and Medina. He now set about the task of civilizing the people. The Coptic was declared the national church, the Catholic priests being driven away, although the Protestant missionaries were suffered to remain. Edicts were issued forbidding the slave trade, polygamy, the emasculation of enemies, and the mutilation of adult captives. Trade and agriculture have been specially favored, and all custom houses from Gondar to Halai have been abolished. In 1855 he issued an order to the Mohammedans to become Christians within two years or to leave the country; and the Galla tribes whose land he has conquered have assumed the Christian faith. In 1856 he subdued Shoa in southern Abyssinia, but the Mohammedan element, which is strong in that region, is not entirely suppressed. John Bell, an Englishman, is his adjutant and engineer, and an English consul resides at his court. The missionary Krapf, who visited him in 1855, says that at that time he not only conducted all his wars in person, but was also personally the dispenser of justice, was quick in judgment, and friendly to Europeans.

THEODOSIUS, a Roman general, beheaded in Carthage, A. D. 376. During the reign of Valentinian he was sent to the defence of Britain, in 367 crossed the channel at the head of a large army, and in two campaigns freed the country from the barbarians, strengthened the fortifications, and confirmed the Roman power. In 370 he returned, was made master-general of the cavalry, and was stationed on the upper Danube, where he defeated the Alemanni. When in 372 Firmus, a Moor, had made himself master of Mauritania and Numidia and Count Romanus, the governor of Africa, unable to oppose, had joined him in rebellion, Theodosius was sent to that country to reduce it to its allegiance. Firmus at first attempted to deceive him by an appearance of submission, but all his arts were rendered unavailing by the prudence and perseverance of Theodosius. At the head of a small body of men, he advanced into the heart of an unknown and hostile country, driving his enemy before him, until at last the usurper fled to Igmazen, king of the Isafenses. The latter being threatened with destruction for harboring him, Firmus

strangled himself, and his dead body was given up by Igmazen. Theodosius recovered Africa, but on the suspicion that his name and services were too great for a subject, he was put to death. From him descended a line of Roman emperors.

THEODOSIUS I., THE GREAT, a Roman emperor, son of the preceding, born in Italica or Cauca, Spain, about A. D. 346, died Jan. 17, 395. He learned the art of war under his father, was early given a separate command and appointed duke of Mœsia, and while occupying that station gained in 374 a victory over the Sarmatians. After the execution of his father he retired to Spain, where he led a private life, cultivating and improving his land. In 378 the emperor Valens was killed and the Roman army terribly defeated by the Goths on the plains of Adrianople; and the surviving emperor, Gratian, summoned Theodosius from his retirement to take the supreme command, declared him Augustus, Jan. 19, 379, and assigned to him the administration of Thrace, Asia, and Egypt, with Dacia and Macedonia. Fixing his head-quarters at Thessalonica, Theodosius carried on the war against the Goths during 4 campaigns (379-382), hazarding no general engagement, but reviving the dispirited Roman troops by attacking the enemy in detail. After the death of Fritigern, the Gothic leader, that nation was broken up by dissensions and jealousies; and Modar, a prince of the Amali, was won over to the Roman cause, and surprised and slaughtered a large body of his countrymen. The Goths were afterward again united under Athanaric, who made peace and visited Constantinople, where he died; and the magnificent funeral honors paid him by Theodosius so won over his followers that they enlisted in the Roman army. In 383 Gratian, the emperor of the West, was dethroned and put to death by Maximus, who sent envoys to Theodosius excusing his conduct and offering him peace or war. Theodosius was not in a condition to accept the latter, and he reluctantly entered into a treaty with the usurper, by which he recognized him as emperor of the countries north of the Alps, Valentinian, the brother of Gratian, being secured the possession of Italy, Africa, and western Illyricum. Theodosius now devoted his attention to the affairs of the church. Although born of Christian parents, he was not baptized until the first year of his reign, when he confessed the orthodox faith. Returning to Constantinople, the stronghold of Arianism, he determined to do away with that creed, and gave to the archbishop Demophilus the alternative of subscribing to the Nicene creed or instantly resigning. Demophilus chose the latter, and Gregory Nazianzen was installed in his place. Six weeks afterward Theodosius commissioned his lieutenant Sapor to expel all the Arian clergy from the churches in his dominions, and gave him a military force sufficient to carry out the decree. In May, 381, he assembled the first council of Constantinople, to confirm and complete the Nicene creed; and dur-

ing 15 years he issued at least 15 edicts against all heretics, especially against those disbelieving the doctrine of the Trinity. In the mean time Maximus, having collected an army of barbarians, entered and conquered Italy, which Valentinian had deserted on his approach, fleeing to Thessalonica. The disposition of Theodosius to undertake the cause of the fugitive emperor was seconded by the tears of Galla, the beautiful sister of the latter, whose marriage with the emperor of the East was the pledge of civil war. His army and navy were quickly assembled, and at the head of a large body of disciplined men he marched against Maximus, encamped at the Pannonian city of Siscia on the Savus, who was defeated and fled to Aquileia; but the gates of the city had scarcely been shut before Theodosius appeared, and Maximus was given up by his own troops and put to death. The emperor of the East, after restoring peace to the provinces, entered Rome in triumph, June 13, 389. At this time the citizens of Antioch, burdened by the expenses of the war, rose in a fury which discharged itself on the images of the imperial family, which were torn down and dragged through the streets. The disturbance was quickly suppressed; but a sentence of terrible punishment was pronounced against the city by Theodosius, who however was finally induced to suspend its complete execution. The people of Thessalonica having for a slight cause murdered Botheric and the principal officers of the little garrison, the emperor sent thither an army of barbarians, who, when the inhabitants were assembled by invitation at the circus, massacred them to the number of many thousands. For his crime in sending the order for this deed, Theodosius was forced by the undaunted Ambrose, archbishop of Milan, to do public penance. The emperor spent 3 years in Italy, and seated Valentinian on the throne of that country. The latter did not long enjoy his elevation, being strangled in 392 by his general Arbogastes, who had secured for himself all the real power of the government, and who now set up as emperor the rhetorician Eugenius. Theodosius undertook again the conquest of the West. He crossed the Julian Alps, and, after a severe and long uncertain contest, defeated Arbogastes in the open country extending from their foot to the walls of Aquileia. He was now master of the whole Roman world. Honorius, his younger son, was called to Milan to receive the sceptre of the West, and here Theodosius died immediately after his arrival. In the eastern empire he was succeeded by his elder son Arcadius. Theodosius, though naturally of a mild temperament, was much influenced by his passions, and many of the measures of his reign were marked by extreme cruelty. His great panegyrist is the poet Claudian. His reign is especially remarkable for the formal destruction of paganism, and for his efforts in this respect his fame is placed by the ecclesiastical writers of the time on a level with that of Constantine.

THEOGNIS, a Greek elegiac poet, who flourished about 548 B. C. He was a citizen of Megara, in Greece; and as in the contests between the aristocratic and democratic parties in that little commonwealth he belonged to the former, he shared in their defeat. He went into exile to Thebes, and during his life visited Sicily, Eubœa, and Sparta. He survived the Persian war of 490 B. C. The fragments attributed to him form the largest collection of gnomic poetry now extant. There have been numerous editions of them, one of the best being that of F. Th. Welcker (8vo., Frankfurt-on-the-Main, 1826).

THEOLOGY (Gr. *theos*, God, and *logos*, discourse), the doctrine of the Divinity and of divine things. The name *theologos* was given by the Greeks to the authors of theogonies (as Orpheus and Hesiod), and to those who wrote poems (as Empedocles) or philosophical treatises (as Pherecydes) on divine things and the origin of things through the gods. A distinction was early made, as by Varro, between "mythical theology," a knowledge of the myths and legends concerning the deities in the classic poets; "physical theology," the investigations of philosophers on the origin of the world; and "civil theology," a knowledge of public worship. In the New Testament the word theology does not occur. The ecclesiastical writers of the 3d and 4th centuries used the word, but applied it only to a part of the doctrines of Christianity, especially to the doctrine of the Trinity, or to the doctrines of the divinity of the Son or the Spirit. Somewhat later the name was used by Theodoret, Maximus, and others, of the aggregate doctrines of the Bible, but its most common signification remained the doctrine of God. Abelard was the first to apply the term to the entire science of the Christian religion, which signification it has since retained. With regard to the sources from which theology derives its contents, it is common to divide it into natural or philosophical theology, which confines itself to the development of the religious ideas resting on rational arguments only, and into positive or revealed theology, which sets forth and systematizes the doctrines of the Scriptures and of the church. A part of revealed theology is biblical theology, which is occupied solely with the investigation and representation of the doctrines contained in the Bible. With regard to the contents of theology, a distinction is made between theoretical theology or dogmatics and practical theology or ethics. Theology, viewed as the whole of religious science, is commonly regarded as consisting of four main branches, historical, exegetical, systematic, and practical theology. These are again variously subdivided, and have several auxiliary sciences connected with them. Thus historical theology embraces the history of the church, of Christian doctrines, of heresies, of councils, &c. To exegetical theology belong the interpretation (exegesis) of the Bible; hermeneutics, the science which teaches the right

principles to be observed in interpreting the Bible; criticism, which examines and tries to establish the genuine original text; the introduction to the Bible, which discusses the time when and place where every book of the Bible originated, its authenticity, and kindred questions. Systematic theology, also called merely theology, comprises the system of Christian doctrines (dogmatics); the system of Christian ethics; symbolics, the comparative statement of the doctrines of several religious denominations, &c. Practical theology includes homiletics, catechetics, liturgics, ecclesiastical law, &c. Polemics and apologetics, which are also often treated as separate branches of theology, belong to several of the above four principal divisions at the same time.—Until the time of Abelard little attention was paid to comprehending theology in its totality, and to establishing the connection of the branches with each other. After him steady progress was made in systematizing theology. Although nearly all the theologians of the middle ages whose writings are extant belonged to the same church, yet they were divided into two fundamentally different schools, the scholastics and mystics. The theologians of the churches which grew out of the reformation of the 16th century followed, in their treatment of theology, either the scholastics or mystics, though the name of the former was discarded both by their Protestant and Roman Catholic followers. A new era in the history of theology was established by the philosophy of Kant, who fully developed and systematized a new theory of Christian theology, commonly called rationalism, which more or less made the belief in a religious doctrine dependent on its demonstrability by reason. This view gained the ascendancy in several Protestant churches, and for a time numerous adherents in many others. Its opponents, who defended the Bible as the absolute rule of faith, were called supranaturalists, and the subsequent history of theology is a contest not yet ended between these two systems. The main arena of this controversy has been Germany, where through Schleiermacher, through the philosophy of the absolute, through Strauss and others, a number of new schools arose in succession, which deeply agitated the entire Christian world. (See GERMAN THEOLOGY.) It has also been attempted to build up theological systems in opposition to Christianity, such as deism and pantheism.—Valuable systematic works, giving a survey of the entire field of Christian theology, have been published by President Dwight, Dr. J. Pye Smith, Professor Hodge, and others, and useful encyclopædic manuals by Hagenbach, Pelt, and Staudenmaier.

THEOPHRASTUS, a Greek philosopher and author, born at Eresus, in the island of Lesbos, died in 285 B. C., according to some at the age of 85, and according to others of 106 years. He studied at Athens under Plato and Aristotle; and when the latter withdrew from the lyceum,

Theophrastus became his successor. The number of his pupils from all parts of Greece was at one time 2,000. His popularity and influence on the public affairs of Greece excited a party spirit against him, and being brought before the Areopagus on a charge of impiety, he pleaded his own cause, and was acquitted. After this he taught in tranquillity until 305, when Sophocles, son of Amphiclideas, carried a law which prohibited all philosophers, under pain of death, from giving any public instruction without the permission of the state. Theophrastus left Athens; but in the next year the law was abolished, and he returned, and continued his labors without interruption until his death. He developed no new system of philosophy, but expounded that of his master Aristotle. He wrote works on politics, laws, legislators, and oratory, which are lost, and "A Dissertation on the Senses and the Imagination," a work on "Metaphysics," "Characters," and two works on botany, "The History of Plants" and "The Causes of Plants," which are extant in whole or in part. The two last are among his earliest works on botany written with any scientific precision, and contain much valuable matter. The book of "Characters" consists of 10 sketches of the general vices of humanity as developed in individuals. All the remains of Theophrastus are contained in the edition of Aristotle printed by Aldus (5 vols. fol., Venice, 1495-'98); the best edition of his works is that of J. G. Schneider (5 vols., Leipzig, 1818-'21). His "Characters" were translated into French and prefixed to his own by La Bruyère, and into English, among others, by Francis Howell, with notes and illustrations and the original text (8vo., London, 1824).

THERA (now *Santorin*), a Grecian island of the Aegean sea, now belonging to the government of the Cyclades, in the kingdom of Greece, is lat. 36° 20' 45" N., long. 25° 32' 58" E.; length about 9 m. from N. to S., breadth about 1½ m.; pop. in 1852, 21,827. It is crescent-shaped, with the concavity on the W. side forming a bay or roadstead partially protected by the small islands of Therasia and Aspronisi. As no bottom is found, vessels make fast to the abrupt and rocky shores in this roadstead. The soil of the island is volcanic and inclined to liness, but very fertile. The annual production of wine is over 1,000,000 gallons. Ship building is the only considerable manufacture carried on. Though an ancient Laedæmonian colony, Thera is only of historic importance as having sent a colony to found the city of Cyrene in Africa, 681 B. C. It possesses much interest to the physical geographer, however, from the volcanic changes which have occurred in it within the historic period. The concave W. side of the island has been proved to be a part of the inner wall of an immense volcanic crater, of which the two islands of Therasia and Aspronisi form a continuation. Soundings made by command of the English admiralty show that this crater is from 1,200 to 2,449

feet in depth, and that it forms a complete bowl except at the northern point between Therasia and Thera, where there is a perpendicular alit a mile in width and 1,170 feet deep midway between the two islands. In the centre of this bowl 4 different islands have risen during volcanic eruptions within the historic period, 8 of which still exist, and are called the Cammenia. The first, then called Hiera (Holy), now Palæa (Old) Cammeni, burst out of the sea with terrible flame and noise in 197 B. C. A second island, which has since disappeared, rose near the first in 67 B. C. A third appeared in A. D. 46, and is supposed to be that now known as Mikia Cammeni (Little Cammeni). Numerous other eruptions and changes occurred down to 1707, when another island, the Nea Cammeni (New Cammeni), was formed, at first composed of white pumice, but subsequently receiving additions of brown trachytic rock, to which the name of Black island was given. The eruption did not wholly cease or the island assume its present form till 1712, since which there has been no volcanic action.

THERAMENES, a native of Coa, who was a political leader at Athens toward the end of the 5th century B. C. In 411 he became a member of the council of 400; but seeing that the downfall of this government was near at hand, he deserted it and became one of the leading agents in its overthrow. In 410 he commanded a portion of the Athenian fleet, which was engaged in cruising about and exacting money from the islands, and finally joined the fleet under Thrasylus, and took part in the battle of Cyzicus, in which he commanded one of the 3 divisions of the Athenian force. He also served with Alcibiades, and in 408 participated in the siege of Chalcedon and the capture of Byzantium. He was one of the inferior generals at the battle of Arginusæ in 406. In the trial of the generals for not saving the crews of the ships after the result of the battle was known, Theramenes came forward as the principal accuser of his colleagues, and it was chiefly owing to his influence that they were convicted and sentenced to death. After the battle of Ægospotami, and during the siege of Athens by the Spartan general Lysander, when the city was reduced to great extremity, Theramenes offered himself to the people as a suitable envoy to the Laedæmonians, declaring that he could detect the real intention of the ephors in regard to Athens, and that also he had influence to obtain for them more favorable terms than any other. He was accordingly sent to inquire and report, but remained 3 months with Lysander, who he pretended detained him that length of time without informing him that the ephors only had power to grant peace; and upon his return to the city, which was now suffering under a terrible famine, he was sent to make peace on any terms. The hard conditions imposed by the Laedæmonians were assented to (see GREECE, vol. viii. p. 448), and in 404 Theramenes, who had during his 3 months' stay

with Lysander made arrangements with the Athenian oligarchical exiles, became one of the thirty tyrants. He warmly supported the first measures of the government in crushing the democracy and putting to death its prominent leaders; but he afterward opposed the violent measures of Critias and his colleagues, who had private hatreds to gratify. His party daily increased; but Critias, after charging him with being a public enemy, caused him to be dragged off to prison by partisans with concealed daggers whom he had brought into the senate house, and compelled him to instantly drink the hemlock. Theramenes was an able though faithless and cunning man; but the heroic manner in which he met his fate, and the fact of his dying in defence of the liberties which he had previously conspired to betray, rendered him a special object of admiration to the ancients.

THERESA, MARIA. See **MARIA THERESA.**

THERESA OF JESUS, SAINT, a nun and mystic writer of Spain, born at Ávila in Old Castile in 1515, died Oct. 4, 1582. At the age of 20 she entered the order of Carmelites in a convent of her native town, in which she remained 27 years. She then became the foundress of a reformed branch of the Carmelites (Barefooted Carmelites), sometimes called after her Theresians. During her life 29 convents of the reformed order were established, and in the 18th century it counted about 2,000 members in 6 provinces, in Spain and Spanish America. Theresa described the internal struggles and aspirations of her heart and her frequent mystic visions in ascetic treatises and letters, which, on account of their theological importance, belong among the most memorable documents of the mystic literature of the Roman Catholic church, while their excellence of language and style has secured for them a place in the history of Spanish literature. She wrote her works reluctantly, and only at the command of her confessor. The following five of them are extant: *Discurso o relacion de su vida*, written in 1562; *El camino de la perfeccion*, prepared in 1568, as a guide for the nuns of her reformed order; *El libro de las fundaciones*, an account of the convents founded by her; *El castillo interior, o las moradas*, written in 1577, and the most celebrated of her mystic works, in which she portrays in glowing colors the gradual progress of the soul to the 7th heaven, the celestial castle of Christ, her spouse; *Santos conceptos de amor de Dios*, the original of which she burned in compliance with an order of her confessor, but which has been preserved from a copy taken by one of the nuns. The original manuscripts of the first four works are preserved in the library of the Escorial by order of King Philip II. The first complete edition of these works appeared at Salamanca in 1587, and a recent one, edited by Ochoa, at Paris in 1847 (*Tesoro de las obras místicas de Santa Teresa de Jesus*). A collection of letters of St. Theresa, addressed to different

persons, was first published at Saragossa in 1658, and often since. All her works have been translated into nearly every language of Europe, and still frequently appear in new editions.

THERMAIO GULF. See **SALONICA.**

THERMO-ELECTRICITY (Gr. *θερμη*, heat, and *ηλεκτρον*, amber). For the principles relating to electric currents, so called, and the methods of indicating and measuring them, see **ELECTRO-DYNAMICS**, and **ELECTRO-MAGNETISM**. Professor Seebeck, of Berlin, was the first to discover, in 1822, that if two metallic bars having different crystalline texture, or unequal conducting powers through any cause, are placed in contact or soldered together, end to end, and heated or cooled at the junction to a temperature different from that of the other parts, and if from the other ends of the bars at the same time, conducting wires be arranged to complete a circuit, the natural electricity of the metals is disturbed, and an electrical current is set up, which is maintained so long as the parts are kept at an unlike temperature. When the bars are of bismuth and antimony, and the junction is heated, the positive current is at this from the antimony to the bismuth, and along the conducting wires from the latter to the former; upon cooling instead, the current is reversed; and when the temperature of the bars becomes equal throughout, the current ceases. An extremely feeble current, indeed, is obtained by unequally heating a single bar, as of bismuth. The currents obtained under either of these conditions are distinguished as thermo-electric; and experiments have determined a thermo-electric series of metals, of which the following is a part: bismuth, platinum, lead, tin, copper or silver, zinc, iron, antimony. These are here placed in such order that any one before gives with any one later in the series, by heat, a current through the conducting wires from the former to the latter. With a given difference of temperature, the current is more intense as the metals are further apart in the series, being the most intense yet known with bismuth and antimony; the current is constant so long as the difference of temperatures is so, as when the junction is kept at 212°, the further ends at 32°, or the reverse; and with given metals, it is more intense as the difference of the temperatures is greater. With any single pair of bars, it is still comparatively feeble; but when the metals of several pairs are alternately connected, and the temperatures of the alternate junctions kept equidistant, as is readily done by bending each bar at right angles at the ends, soldering, and arranging so as to bring any number of pairs into a square prismatic pile, having the length of a single bar, with non-conducting strips between the bars, and the terminal ones connected by conducting wires, the intensity of the current is then, as in the galvanic battery, precisely multiplied by the number of the pairs. Such an arrangement, devised by MM. Nobili and Melloni, is a thermo-electric

pile; the ends of the bars in the opposite directions form the two "faces" of the pile; laterally this is enveloped in a sheath, protecting all but the faces; and in this sheath, communicating respectively with the free antimony and bismuth bars at the extremities of the pile, are two cups, termed the poles of the pile. The number of pairs may be 80 or more; and as the size of the bars does not influence the strength of the current, these may be very small, and if desirable no more than an inch in length. Now, when one of the faces is kept at a given temperature, and the other exposed to a source of heat or to cold, even though this be very feeble, yet the multiplying effect of the number of pairs produces a current strong enough to give a very sensible deflection to the needle of a galvanometer with which the poles are connected; and the instrument forms by far the most delicate means known for the detection of feeble degrees of heat, and thus determining the behavior of various substances in reference to radiation, transmission, &c., of this agent. In the complete apparatus, known as the "thermo-multiplier," there are screens for protecting at will either face of the pile; a lamp and reflector for emitting radiant heat; a stand to support the substances to be experimented upon; and a hollow metallic cone, polished within, for concentrating the rays of heat, when required, upon one face of the pile. In Melloni's pile of 80 pairs, the indications of the needle are strictly proportional to the temperature only to 20° of deflection; and beyond this corrections must be introduced. Deflection of 85° corresponds to unequal heating of the faces through 6°-8° temperature. For an example of the sensitiveness of the instrument, as well as for the most important results thus far attained by its use, see DIATHERMANY.

THERMOMETER (Gr. *θερμῶν*, heat, and *μετρον*, measure), an instrument designed, by means of the visible or mechanical effect of heat upon some part or substance entering into its construction, to show, and sometimes also to register, the temperatures or sensible heats of the bodies or spaces to the influence of which it is exposed. For the general principles upon which the invention and use of the thermometer are based, see EXPANSION, and HEAT (I.); and for the difference between the actual and the apparent or sensible heat of bodies, with the modes of measuring the former, see CALORIMETER, and HEAT (III.).—The first attempt at indicating to the eye differences of temperature, seems to have been by the contrivance variously ascribed to Drebbel of Holland and Sanctorius of Italy, about the beginning of the 17th century, and known as a weather glass. This was very rude and inaccurate, consisting of a glass bulb and tube inverted, opening below into a cup of colored liquid, which, the air of the bulb having been partly expelled by heat, rose in the tube, and stood at different heights according as the air remaining in the bulb was more or less expanded by heat. This,

the origin of the common air thermometer, as improved by Boyle and by the Florentine academicians, became transformed to a smaller bulb with upright stem of somewhat fine bore, the contained liquid being colored spirits of wine; boiling this to expel air, the tube was hermetically sealed, and the whole then affixed to a case. A scale of degrees was also introduced, its fixed points being the cold of snow or ice and the greatest heat known at Florence; it was of necessity very variable in its indications. At this stage in the progress of thermometry, much discussion in regard to the most suitable fixed points for the scale, the best substance for use in the instrument, &c., including that of the question whether water did not freeze at different temperatures in different latitudes, was carried on in England and on the continent. Hooke advocated as the lower fixed point the temperature of freezing water; but Newton seems first to have discovered or taken advantage of the facts, that a thermometer placed in melting snow or ice always indicates the same temperature, and always very nearly one temperature in boiling water. But of oil, which he suggested for the liquid in the bulb, the movements were found to be too sluggish and uncertain. Römer, overcoming a prejudice that seems to have existed in regard to unequal expansion of mercury, first adopted that liquid; and he doubtless devised the instrument and scale usually attributed to Fahrenheit of Amsterdam (1720); the latter constructing and introducing the instrument, so that it became generally known throughout Europe in the first half of the 18th century. Of this thermometer, the lower fixed point, or zero, was taken at 82° below freezing point of water; but whether as the cold obtained by its maker by mixing salt and snow, or as the greatest cold observed in Iceland, and in either case as the supposed point of absolute cold, is not now definitely known; and since Fahrenheit kept his graduation of thermometers a secret, the same must be said respecting the choice of a scale of 180° between the fixed points, though this is supposed to have originated in some theoretical views as to the dilatation of mercury. Celsius of Sweden (1742) introduced a scale of 100° between the fixed points; this was adopted in France at the time of the revolution, and named the *thermomètre centigrade*; and owing to its convenient decimal division, it has been wholly adopted in several countries of Europe, while it is coming into general use among scientific men throughout the world. An advantage of Fahrenheit's scale, in many instances, is still that the less range of the degree saves the necessity of so often resorting to fractions in the expression of temperatures; its real fault and opprobrium is its needlessly fixing the 0 elsewhere than at the freezing point; and perhaps, could its zero be restored to the true place, and the range from this to boiling point be divided into 160°, the utmost convenience and perfection of

a thermometric scale would be attained. The scale of Réaumur is 80° between the fixed points; and that of De Lisle, now little used, is 150° , taking the zero at boiling point and reckoning downward.—Obviously, the expansive effect of heat upon any convenient solid, liquid, or gas, can be made the measure and indicator of temperatures; and for the purpose each of these three forms of matter is in use. For ordinary use, however, the simple expansion of a solid is too small, and that of a gas too great, and difficult to measure. Liquids have an intermediate range of expansion, and are hence more conveniently managed and observed; and of the different liquids which offer some features of convenience, mercury is readily determined to be the most eligible for general employment, by the nearly equal rate of expansion throughout the range between its solidifying and its subliming in vapor; by the great extent of that range, more than 700° F.; by the rapidity with which it acquires the temperature of the space it is in; by its slight tendency to adhere to the glass tube; and by the readiness with which it is freed of air. In making a mercurial thermometer, a glass tube with bore of capillary size, and this as nearly as may be of uniform capacity throughout, is selected; the approximate uniformity being readily tested by introducing a short column of mercury, impelling it by air through the tube, and observing whether it preserves nearly equal lengths throughout. Outting the tube to the required length, a bulb is blown upon one end in the usual method of glass-blowing, but, to avoid moisture, with air from a rubber bag. The greater the capacity of the bulb, as compared with that of the tube, the greater the length of tube that will be filled by a given degree of expansion of the mercury, and so the greater the delicacy of the indications, i. e., the power of showing slight changes of temperature. The bulb is more commonly made spherical, and this form best resists any effect of varying pressures of the atmosphere; but for sensibility in point of time, or quickness of response to the acting temperature, that affording, with a given quantity of mercury, the largest surface is best; and this quality, others being disregarded, is secured by the cylindrical bulb, which is usually straight, sometimes coiled. A small cup is now cemented to the open end of the tube, or a paper funnel introduced into it; into either some mercury is put; the bulb is heated with a lamp to expel air, and then left to cool, when the atmosphere forces in mercury, partly filling it. The lamp is applied again, and the mercury boiled some minutes to expel air and moisture; upon subsequent cooling, mercury from the cup or funnel alone enters, completely filling the bulb and tube. Emptying the cup, this is removed by heating with a blowpipe, at the same time drawing the upper end of the tube to a narrow neck; and then, by reheating the instrument to the highest temperature it is expected to show, the excess of mercury over just enough to fill the bulb

and tube at such temperature is expelled; removing the lamp, as soon as the column begins to contract, the flame is directed upon the end of the tube, hermetically sealing it. In contracting upon cooling, the mercury withdraws mainly into the bulb, leaving much of the tube vacuous, save that it may contain an extremely rare mercurial vapor; and the instrument is now complete, except the graduation and mounting.—It will be evident that we know nothing of absolute temperature, except theoretically; that the range of actual and possible temperatures reaches beyond our powers of detection, both upward and downward, and to an indefinite extent, so as to be comparable to an endless chain of which we can discover only so many links at some part of its course; that any temperature we may choose for our fixed point must be simply arbitrary; and yet, that by selecting two such fixed points, dividing the intervening range into a fixed number of degrees, and extending this scale by equal intervals of sensible temperature both above and below the fixed points, we introduce a sufficient and accurate means of measuring and comparing the temperatures we can observe. The only peculiar fitness of the fixed points that have been selected, is in their being the most nearly invariable, and the most convenient in practice. In Fahrenheit's scale, the freezing point of water is called 32° , the boiling point 212° , the intervening range thus being divided into 180° ; in the centigrade, the freezing point is 0° , the boiling point 100° ; all temperatures above the 0, in either of these scales, being considered, and when needful marked, +, and all below 0, —. Though the rate of expansion of pure mercury increases slightly with the rise of temperature (see EXPANSION), yet both the amount and the variation are known; and by this amount, 1 part in 55.08 between the fixed points, the capacity of the tube between the heights of column in it showing the freezing and boiling points, will be precisely $\frac{1}{55.08}$ of the whole capacity of tube and bulb below freezing point. If, now, thermometer tubes of perfectly uniform bore could be had, and the expansion both of the mercury and the glass tube containing it could also be supposed uniform, then the rise of the column in such a thermometer would be through its whole range precisely proportional to the expansion, and precisely equal for the same number of degrees in any part of the scale. All these suppositions, however, fail in the fact. To find the freezing point, the bulb and the tube, to very nearly the height to which such cold will lower the column, are kept immersed in melting pounded ice or snow, long enough to bring the mercury and glass throughout to the freezing temperature; the contraction and relative volumes of both are thus rightly secured, and the point below which the mercury column ceases to fall is marked on the tube with a file. Water boils at temperatures varying not only with the atmospheric pressure, but also with the purity of the water itself.

with the kind of vessel, and state of its surface; but the temperature of the steam or yet uncondensed vapor freely arising from it does not vary with these latter conditions, but in strict relation with the pressure merely. Hence, to find the boiling point, the instrument is next immersed, not in boiling water, but within the steam freely escaping from it (the best apparatus for the purpose being that of Regnault), and when the barometer shows a fixed atmospheric pressure of 29.92 inches of mercury. In this also the instrument remains until the glass and mercury have throughout acquired the temperature of the steam; then, their expansions being completed, and the column ceasing to vary, the height is marked as before. If the barometer indicates any other pressure than that above given, a correction must be made, and the true boiling point marked higher or lower than that shown at the time; the correction being by a space corresponding to 1° F. for every .59+ inch of the barometer. The different thermometric scales are readily reducible to each other; rules for the reductions most commonly required, representing any given number of Fahrenheit degrees by F° , of centigrade degrees by C° , &c., are thus briefly expressed: To reduce

Fahrenheit to Centigrade.....	$\frac{1}{2}$	$(F^{\circ} - 32) = C^{\circ}$
Centigrade to Fahrenheit.....	$\frac{1}{2}$	$C^{\circ} + 32 = F^{\circ}$
Fahrenheit to Réaumur.....	$\frac{1}{2}$	$(F^{\circ} - 32) = R^{\circ}$
Réaumur to Fahrenheit.....	$\frac{1}{2}$	$R^{\circ} + 32 = F^{\circ}$

—The principal sources of error in the mercurial thermometer, and inseparably connected with the instrument, however accurately constructed, arise from the inequality of caliber of the tube, and of the expansions of the mercury and glass. The caliber probably always varies slightly in different parts of the tube, beside that, from the usual method of drawing out the tubes, it is likely to be in form a very much elongated hollow cone. Hence, to make a standard or highly perfect thermometer, it becomes necessary in the outset to place the tube upon the carriage of a dividing engine for rectilinear scales (briefly alluded to under DIVIDING ENGINE, and of which that by Duboscq, of Paris, is the best now made), and moving through the tube a short column of mercury, to mark on it, by means of a small microscope with cross wires, and the graver of the instrument, the lengths of this column in the different parts. This process is the calibration of the tube. Dividing all these lengths with reference to some arbitrarily assumed number of degrees, or rather parts, a new and wholly arbitrary, but (for the caliber) perfect scale, is obtained; exposing to the vapor of hydrofluoric acid, the marks of the graver are more plainly etched upon the tube; and it is then verified by recurring to the use of the engine. The arbitrary degrees are then to be reduced to degrees of the scale required, and these being properly marked, and of course differing in length in different parts, a standard instrument is obtained. For a more full statement of the

mode of calibration, see Professor J. P. Cooke's "Chemical Physics," vol. i. (Boston, 1860), or the original memoirs of Regnault, *Mémoires de l'Institut*, vol. xxi. pp. 329, 328. Still, the rise observed in a thermometer tube is not the absolute expansion of the mercury, but the relative expansion, or difference between the increase of volume of the mercury and of capacity of the bulb and tube. Mercury expanding about 7 times more than glass, its relative is about $\frac{1}{7}$ less than its absolute expansion. Again, in view of the fact merely that mercury expands more rapidly at higher temperatures, the lengths of the degrees forming the scale should increase slightly from zero up, in order that these may correspond with equal variations of actual temperature. In thermometers generally, the marked degrees are of the same length throughout the scale; or they are of equal length between certain points ascertained by a standard, and correspond mathematically, not thermally, for all temperatures beyond the highest and lowest points so found. The error arising even from equal division between freezing and boiling points is very slight, since the degree has a mean length, a little too long below and too short above; but carrying the same divisions above boiling and below freezing point, it results that in the former part of the scale the temperature indicated is always higher, and in the latter part lower, than the actual temperature. Again, generally, the rate of expansion of glass increases about equally with that of mercury; and this fact sometimes nearly or quite corrects, or even over-compensates the variation in the volume of the mercury. But such correction cannot be relied on, since the rate of expansion differs much in different kinds or manufactures of glass, and even in the same tube under different circumstances. A result is, that two thermometers constructed with the greatest care seldom continue to agree through points much above or below the fixed points; and the uncertainty concerning the behavior of the glass must render absolute accuracy unattainable, and must introduce the question of possible variation into all scientific data collected from observations with two or more of these instruments. For the rates of variation in expansion of different kinds of glass, as determined by Regnault, see the works above referred to. It may be remarked, however, that good flint glass is best for the tubes, as most nearly and uniformly compensating the change in the mercury; while common or crown glass is irregular and less trustworthy. For the more accurate, or standard thermometers, the scale should be engraved on the tube itself, since the unequal expansion of a metal or ivory case or strip may introduce new sources of error; this effect is very nearly obviated, in the careful manufacture of the better class of common instruments, if time enough be allowed the tube, mercury, and case to acquire throughout the same temperatures, and the marking be carefully done. The length of the degree on

the scale, and hence the delicacy or minuteness of indication of temperatures, depending on the relative capacities of bulb and tube, there is a gain in this respect from making the bulb large and the tube exceedingly fine. But, again, the large bulb is liable sensibly to reduce the temperature of the very medium or mass tested, and especially when the volume of the latter is small; while for sensibility in the way of quick response, also, the smaller the bulb the better. Hence, the effort is directed rather to securing smallness of caliber in the tube; and to allow of this, the back of the tube is enamelled white to show the column by contrast, and the bore is flattened or made elliptical, a broader side standing toward the eye. In the most delicate scales, the subdivision is seldom carried beyond 20 parts to the centigrade degree; a practised eye will then read to hundredths of the degree. The eye in careful reading should always be at the level of the top of the column; and the aid of a small telescope may be employed. In using a standard thermometer, both bulb and stem should be immersed in the medium; if this be impossible, a correction must be made for the length of column in the tube unacted on; and when the mass of the bulb itself must sensibly abstract from the temperature to be observed, a further correction for this error is required. Mercurial thermometers are liable to error from still other and more singular conditions. Owing to some change in the glass, either due to continued pressure of air, or more likely to slow rearrangement of the particles following the molecular disturbances by melting and blowing of the glass, the zero point slowly rises through a year or more, and sometimes to an extent of 1° or 2° . Hence, the tubes must never be used immediately after making, but laid aside at least 10 or 12 months before sealing and graduation. Despretz finds that this change may continue for an indefinite period. But sudden variations also occur, and either transient or permanent. As an example of the former, if a thermometer used for some time for ordinary temperatures have its zero point verified, and be then exposed for very little time to a heat at or above 212° , upon testing the zero point immediately after, it will be found (probably through permanence in degree of the expansion of the glass) lowered by $.1^{\circ}$ to $.2^{\circ}$; and it may be some weeks in recovering its former position. In view of all these circumstances, it becomes necessary frequently to verify anew the 0 point in instruments for accurate observation. The utmost attainable accuracy is however secured only by use of a perfect air thermometer. (See Regnault's, in Cooke's "Chemical Physics," p. 584.) The common, cheap thermometers serve very well for such uses as observing the temperature of a room or a bath; but, as graduated with less precision, by comparison with a standard in a water bath, they are necessarily inaccurate, and differ much from each other, especially below 0° F. or much above the boiling

point. Owing also to the very rapid contraction of mercury near its point of congelation, -39° F., the temperatures shown by any mercurial thermometer much below 0° F. are deceptive, being apparently lower than in reality; and such errors have even arisen as that of supposing that in some instances the mercury itself had not congealed until reaching -41° or -46° . Alcohol, commonly used where temperatures much below 0° F. are to be observed, is liable at such range to much variation, although it does not freeze even at -182° F.; and Capt. Parry, in his arctic voyages, observed differences of full 10° C. between alcohol thermometers by the best makers. For measurement of temperatures considerably above the boiling point of water, see PYROMETER. Bréguet's metallic thermometer is an application of the unequal expansions of different metals; a compound bar of platinum, gold, and silver is rolled into an extremely thin ribbon, which is coiled into a spiral, the platinum outermost, one end being fixed and the other acting on an index moving over a circular scale; the silver, expanding most with heat, tends to unbend the spiral, and moves the index. This thermometer is both exceedingly sensitive and accurate, and can be used for very high temperatures. Mr. Victor Beaumont, of New York, constructs a cheap and serviceable metallic thermometer, on the principle of the compound metallic bar carrying an index; the necessity of transmitting the movement through several pieces is likely to introduce inequalities of indication, but probably no more than in good mercurial thermometers; while advantages of these instruments are, that they are portable, prompt, and easily read, and may be used to measure temperatures ranging from below -89° to $1,900^{\circ}$ F. A differential thermometer is a modification of the air thermometer, in which two large glass bulbs above are connected by a glass tube bent twice at right angles; the horizontal and parts of the upright tubes are filled in the common form with a colored liquid, which is depressed on either side as the corresponding bulb is more heated; thus the instrument indicates differences of the temperatures to which the two bulbs may be exposed. It is very sensitive; and by a scale the results it affords are comparable with each other.—It is often important to have means of knowing the highest or lowest temperatures, or both, occurring during a period when, or in situations such that, the observer cannot be present; and for this purpose, the registering instruments known as maximum and minimum thermometers have been devised. One of the simplest and best known is Rutherford's maximum and minimum. Two thermometers are affixed upon the same plate, their tubes bent at right angles just above the bulbs and placed horizontally, each with its scale. The maximum thermometer has in front of the mercury column a short piece of iron wire, which is pushed along by the ad-

vancing column, and left at the point where this begins to recede. For a new observation, the wire can be brought back to the column by moving a magnet near the tube, without. This wire, or index, is in transportation or handling liable to enter the mercury, and cannot usually be recovered without returning the instrument to the makers for refilling; so that many other forms of maximum have been devised to obviate this liability. Rutherford's minimum, however, sufficiently answers the desired purpose; it is filled with colored alcohol, and contains floating in this a small enamel cylinder, with beads on its ends nearly of the size of the bore. The alcohol in expanding readily passes this index, but in contracting, by adhesion it draws it back along with the head of the column, and thus leaves it at the lowest point reached. For a new observation, it is only necessary to tilt down the tube, when the index moves along to the head of the alcohol column again. As an improvement of the maximum thermometer, Prof. Phillips, of England, detaches a small portion of the mercury column by an interposed bubble of air, to serve as the index; while the instruments of Six and Walferdin are capable of great accuracy, and without risk of derangement, but require considerable trouble in their management. In Negretti and Zambra's maximum, in a short, obliquely ascending portion of the tube, between the bulb and the horizontal part, is fixed a small enamel rod, which, though it does not close the tube against the force of the expanding mercury, presents obstruction sufficient to break the column, if kept horizontal, when it begins to return; the column thus preserves almost exactly the greatest advance made, and shows the highest temperature to which it has been exposed. To prepare for a new observation, the instrument is held vertically and shaken, when the mercury returns; this operation, however, may lead to accident. Mr. James Green, of New York, appears (1860) to have removed the objections to the previous forms of maximum thermometer, and produced a highly simple and perfect instrument. In this the tube is straight throughout, but the bore is for a short space just above the bulb contracted to very small size—this being readily accomplished with the elliptical bore by compressing the tube upon the posterior side; and the size is made such that, while expansion forces the mercury through in regular and minute pulses or globules, the space upon the mercury's tending to return proves so small that the cohesive forces give to the liquid, as in the last named, the globular surface (usually ascribed to repulsion of the glass), and so break the column, leaving it to show, as above, its highest point. The instrument is provided with a suitable support, from a pin upon which it can be safely swung with a pendulous or revolving movement, when the centrifugal force suffices to return the mercury, as required for a new observation. For an account of Mr. S.

W. Hall's thermograph, or continuously registering thermometer, for meteorological observations, see "Journal of the Franklin Institute," June, 1859; and for Dr. James Lewis's registering metallic thermometer, see "Annual of Scientific Discovery" (Boston, 1861).—The following are among the points of peculiar interest in the known range of temperatures:

-220° F.	Greatest artificial cold measured (Natterer).
-166° "	" " " " (Faraday).
-150° "	Liquid nitrous oxide freezes.
-71° "	Liquid carbonic acid freezes.
-70° "	Greatest natural cold observed at Fort Reliance, by Beck. (Doubtful).
-55° F.	Estimated temperature of planetary space.
-56° "	Greatest natural cold observed by a verified thermometer (Sabine).
-47° F.	Sulphuric ether freezes.
-39° "	Mercury freezes.
-7° "	Water with alcohol, in equal parts, freezes.
+20° "	Strong wine freezes.
32° "	Water freezes.
50.70° "	Mean temperature of London.
81.8° "	Mean temperature at the equator.
99.5° "	Mean temperature of human blood.
117.8° "	Highest natural temperature observed, in Upper Egypt (Bueckhardt).
930° F.	Red heat (Daniell).
1,141° "	Heat of a common fire (Daniell).

Melting points: Tin, 442°; lead, 554°; silver, 2,288°; cast iron, 2,419°.	

THERMOPYLÆ, or simply PYLÆ (from *Σεπμος*, hot, and *πύλη*, gate), a celebrated defile between Thessaly and Locris, the only passage for an enemy from northern into southern Greece, situated between Mt. Ceta and an inaccessible morass forming the edge of the Maliaç gulf. Between these two was a road wide enough only for a single wheel track, which formed the western gate. At about a mile to the eastward Mt. Ceta again approached the sea in a similar manner, and the passage there formed the eastern gate. The space between these two gates was wider, but full of warm springs, which, many years before Leonidas occupied the pass, the Phocians had so conducted over the ground as to render the pass impracticable. They had also built a wall near the western gate to prevent the incursions of the Thessalians, which was in ruins when the Lacedæmonians came. The present appearance of Thermopylæ is different, owing to the change made in the configuration of the road and the course of the rivers. The Maliaç gulf has been rendered smaller by the accumulation of deposits made by the rivers; the mountain is not now near the sea; the course of the Spercheus has been changed, emptying now into the sea S. of Thermopylæ instead of N. of the pass, as it did in the time of Herodotus; the rivers Dryas, Melas, and Asopus, which when Herodotus wrote reached the sea between Thermopylæ and the mouth of the Spercheus, have now become affluents of the latter; and the level of the soil has been raised by the deposit from the warm springs. The defence of this pass made by Leonidas has immortalized its name. (See *GREECE*, vol. viii. p. 442.) It has also been since that time the scene of several memorable actions. Through the neglect

of the Athenians, and against the earnest remonstrances of Demosthenes, Philip was allowed to occupy it, and thus gain a foothold in southern Greece. Here the Greeks assembled in 279 B. C. to repel Brennus and the Gauls, and in 191 Antiochus the Great of Syria ineffectually labored to prevent the Romans from passing the defile. Several severe contests also took place here during the late Greek war of independence. On the heights above Thermopylæ the remains of three Hellenic fortresses are still to be found.

THÉROIGNE DE MÉRICOURT, ANNE JOSEPH, or LAMBERTINE, a noted woman in the French revolution, born at Méricourt, in the vicinity of Liège, in 1759, died in 1817. Though the daughter of poor peasants, she received an excellent education, but had to leave her native village on account of her dissolute life. Becoming acquainted with the Prussian baron so famous as "Anacharsis Clootz," she removed with him to Paris, became known as a courtesan, was on terms of intimacy with several of the revolutionary leaders, and took a large share in all insurrectionary movements. She was instrumental in bringing about the popular manifestation of Oct. 5 and 6, 1789, was loud in her denunciations of the queen, and entered Paris in triumph at the head of the dreadful procession which brought the royal family from Versailles to the Tuileries. On July 17, 1791, she figured in the mob dispersed in the Champ de Mars by the national guard under Lafayette and Bailly. Having visited her native country with a view to revolution, she was arrested, taken to Vienna, and imprisoned, but at the end of a few months sent back to France, where she assisted in the insurrections of June 20 and Aug. 10, 1792. On the latter day she mercilessly murdered Suleau, the editor of the *Actes des Apôtres*, who had ridiculed her in his paper, cut off his head and put it on the top of a pike, while trampling his corpse under her feet. She also shared in the massacres of September. A little later, being suspected of acting in behalf of the duke of Orleans and conspiring with the Girondists, she lost her popularity; and having once undertaken to vindicate Brissot in the Tuileries garden, she was seized by a number of enraged women, who stripped her and publicly whipped her. She became a raving maniac, and was confined in La Salpêtrière, where she remained insane for years.

THESEUS, the great legendary hero of Attica, was according to the commonly received legends the son of Ægeus, king of Athens, and Æthra, daughter of Pittheus, king of Trœzen. Ægeus upon his departure from Trœzen hid his sword and shoes under a stone, and charged Æthra if she gave birth to a son to send him to Athens as soon as he was able to roll away the stone. When he arrived at maturity his mother informed him of his parentage, and taking possession of the tokens he set out for Attica by land instead of sea, as the

country was infested with robbers, and he was anxious to signalize his prowess. On the road he destroyed various robbers and monsters, and arriving at Athens was recognized by his father, but narrowly escaped death from the hands of Medea. He also engaged in a war with the Pallantids, the sons and grandsons of Pallas, the brother of Ægeus, in regard to the succession to the throne, and was victorious. His first great exploit was the capture of the Marathonian bull, which had ravaged the neighboring country. In this same enterprise Androgeos, son of Minos, king of Crete, had perished; and in return the Athenians had been compelled to send to Crete every 9 years a tribute of 7 young men and 7 maidens to be given up to the Minotaur, who were offered to him in a labyrinth constructed by Dædalus, from whose numerous passages no one could escape. When the third period for sending the victims arrived, Theseus came forward and offered himself, with the intention of slaying the monster. Arriving at Onosus, he gained the affections of Ariadne, daughter of the king of Crete, and was furnished by her with a sword and a clue of thread, with which he killed the Minotaur and escaped from the labyrinth. Hereupon he quitted Crete with his companions, carrying off Ariadne, whom however he left behind at the island of Naxos. It had been agreed that in case the expedition should be successful, Theseus on his return should hoist white sails instead of the black ones which this vessel was in the habit of carrying; but this arrangement was forgotten, and Ægeus, imagining his son was destroyed, threw himself into the sea. Theseus now ascended the throne, and was engaged in a war against the Amazons, who had not recovered from the losses sustained by them from the attack of Hercules. He invaded their territory, defeated them, and carried off their queen Antiope. In revenge these formidable women crossed the Cimmerian Bosphorus on ice, entered Attica, and marched to Athens itself, and were finally vanquished after a long and bloody battle in the streets of that city. Beside these there are but few of the ancient heroic enterprises in which Theseus does not figure. He was one of the Argonauts, was engaged in the Calydonian hunt, fought with Pirithous and the Lapithæ against the Centaurs, and also assisted Adrastus in regaining the bodies of those slain before Thebes. Aided by Pirithous, he carried off Helen from Sparta when she was only 9 years old. Attica was in consequence invaded by Castor and Pollux. Menestheus incited the Athenians to rise against their ruler; and Theseus, finding it impossible to sustain himself, retired to the island of Scyros, where he was destroyed by the treachery of King Lycomedes. In 476 B. C. the oracle directed his bones to be brought from the island to Athens, but it was not until 469, when Scyros was taken by Cimon, that it was pretended the body was found. His bones were laid in the interior of the city, and the

temple called the Theseum, built over the spot, served as a sanctuary for poor men in dread of the powerful, and for slaves in case of cruel treatment. At the battle of Marathon Theseus was reported to have been seen armed and aiding the Athenians against the barbarians. Festivals in his honor were celebrated on the 8th day of each month, and the festival termed Oschophoria was said to have been originated by him after his arrival from Crete. To him was popularly ascribed the origin of the Pyanepsia and the re-institution of the Pythian games. Thucydides states that the great political revolution, by which the petty independent states of Attica were consolidated into a united body with Athens at its head, was believed to have been effected by him; but there is no more historical proof of this than that he was actually a living person. The account of him throughout is entirely legendary, although the later writers endeavored to give it a historical coloring.

THESIGER, SIR FREDERIC (Lord Chelmsford), an English statesman and jurist, born in London in July, 1794. In 1808 he entered the navy as midshipman on board of a frigate, and in 1807 was present at the bombardment of Copenhagen; but on the death of his elder brother he left the navy and entered the profession of law, and in 1818 was called to the bar at Gray's Inn. He rapidly acquired great reputation, especially in the conduct of election cases, and in 1834 was appointed a king's counsel. He entered parliament in 1841 as member for the borough of Woodstock, and held a seat for different constituencies till 1858; his first speech was made in opposition to the war with China. In 1844 he was made solicitor-general in the administration of Sir Robert Peel, and knighted, and in 1845 succeeded Sir W. A. Follett as attorney-general, but the year following resigned on the retirement of his party. While a member of this government he strongly supported the free trade policy. In 1852 he was reappointed attorney-general in the administration of the earl of Derby, which in November gave place to that of Lord John Russell. On the return of Lord Derby to power in March, 1858, he was made lord chancellor and raised to the peerage as Baron Chelmsford, retiring with the rest of the cabinet in April, 1859.

THESPIA, the founder of Greek tragedy, a native of Icarus in Attica, flourished in the time of Pisistratus. The ancient traditions represent him as the inventor of tragedy, and to him is also ascribed the invention of masks. According to one account, probably a misconception, though sanctioned by Horace, Thespia was in the habit of travelling through Attica at the time of the festival of Dionysus in a wagon, and upon this portable stage performed comic plays. Another statement is that he found tragedy already existing in Athens, but that he made in it the simple and important alteration of introducing an actor for the sake of giving rest to the chorus. Of

the character of his tragedies there is also doubt, some maintaining that they were wholly satyric in their nature, others again that he wrote serious compositions. His tragedies have all perished, but the titles of 4 have been preserved. Of the personal history of Thespia scarcely any thing is known except that his first representation was in the year 585 B. C.

THESSALONIANS, EPISTLES TO THE, two canonical books of the New Testament, addressed to the church at Thessalonica by the apostle Paul. They are expressly referred to by Irenæus, Clement of Alexandria, and Tertullian. In modern times the authenticity of both epistles, and especially of the second, has been doubted by J. E. Ch. Schmidt (in his "Introduction to the New Testament"), by Baur (*Paulus der Apostel Jesu Christi*, p. 485 *et seq.*) and the entire Tübingen school, by Weisse (*Philosophische Dogmatik*, vol. i. p. 146), and many others; against whom special treatises in support of their authenticity have been written by W. Grimm (*Die Echtheit der Briefe an die Thessalonier*, 1850), Reiche (*Authenticitas posterioris ad Thessalonenses Epistolæ Vindiciæ*, Göttingen, 1880), Lünemann (in the introduction to his commentary on the two epistles), and others. The first epistle to the Thessalonians is, according to the common opinion, the first of all the Pauline epistles in point of time, and is supposed to have been written soon after the foundation of the church during Paul's first sojourn at Corinth, when Silas and Timothy had returned from Macedonia, about A. D. 52 or 53. The immediate occasion for this epistle seems to have been the favorable report which Timothy had brought of the faith of the Thessalonians, and the desire of the apostle to strengthen this faith. It consists of two parts: the first (chap. i. to iii.) contains an expression of the feelings of the apostle respecting the religious condition of the Thessalonians, and the reception which the apostle found with them; the second part contains an exhortation to holiness (iv. 1-12), an instruction on the fate of the dead at the expected return of Christ (iv. 13-18), an admonition to be always prepared for that event (v. 1-11), several other admonitions, and the conclusion. The second epistle was written soon after the first, in the year 53 or 54, and was evidently designed to correct some mistakes into which the church had fallen, especially respecting the coming of Christ. The apostle commends the Thessalonians for their patience and faith in their persecutions, and announces that those who trouble them will be punished (ch. i.); he shows that the arrival of Christ was not near at hand, but must be preceded by a great apostasy and the appearance of the Antichrist (ii. 1-12), and gives them appropriate admonitions (ii. 13-17, and iii.).—There are special commentaries on these epistles by Flatt (Tübingen, 1829), Schott (Leipsic, 1884), Jowett (London, 1856), Lünemann (Göttingen, 1859), Ellicott (2d ed., 1862), and others.

THESSALONICA. See **Salonica.**

THESSALY, the largest political division of ancient Greece, comprising in its fullest extent that tract of country lying between Thermopylæ and the Cambunian mountains in one direction, and between the range of Pindus and the Ægean sea in the other. Thessaly proper, however, was the plain included between the Cambunian mountains on the N., Ossa and Pelion on the E., Mt. Othrys on the S., and the Pindus range on the W. This plain, whose natural enclosure of mountains is broken only at the N. E. by the vale of Tempe, was the most fertile region and the largest space of land continuously productive in Greece, and was supposed by its inhabitants to have once been a lake, of which the lakes Nessonis (now Karatjair) and Bœbeis (Karla) were the remains. It was drained by the river Peneus and its tributaries, and was divided into two plains, which in antiquity were called Upper Thessaly and Lower Thessaly; the former embracing Thessaliotis and Histiaotis, lying between Æginium in the N. and Thaumaci in the S., and having Pharsalus for its chief city; the latter, Pelasgiotis, stretching from Mts. Titarus and Ossa on the N. to Mt. Othrys and the gulf of Pagassæ on the S., and having Larissa as its most important town. Thessaly proper was early divided into the four districts of Thessaliotis, Histiaotis, Pelasgiotis, and Phthiotis; and this division, the origin of which is sometimes ascribed to Alenæas, the founder of the Alenadæ, was continued down to a very late time. In addition to Thessaly proper, the name was extended over Malis, a narrow valley lying between Mts. Othrys and Eta, and through which the river Spercheus enters into the Maliaë gulf; and to Magnesia, a region lying along the coast and stretching between the vale of Tempe and the gulf of Pagassæ.—The Thessalians were said to have been originally emigrants from Thesprotia in Epirus, who conquered the Pelasgian inhabitants of the plain of the Peneus, which is said by Herodotus to have then been called Æolis. During the historic period there were 8 classes inhabiting the country. The first was a body of rich oligarchical proprietors, who owned most of the soil. Of these the most powerful families were the Alenadæ of Larissa, the Scopadæ of Crannon, and the Creondæ of Pharsalus; the second were the subject Achæans, Magnes, and Perrhæbi, who however retained their tribe names and separate votes in the Amphictyonic council; the third were the Penestæ or serf cultivators of the soil, who could not however be sold out of the country, and who kept up among themselves the relations of family and community. The fertility of the plain, upon which grain and cattle were raised in abundance, supported a large population, and especially a proud, disorderly, and faithless, but at the same time hospitable nobility. As here the finest horses in Greece were bred, Thessaly was distinguished for the excellence of its cavalry; but its in-

fantry is little mentioned. The four divisions of the country formed a political union, existing rather in theory than in fact; and to enforce obedience to the common authority a chief or *tagus* was sometimes elected; but there were almost constantly feuds between the larger cities, each of which had dependent upon it a number of smaller towns. The language was a variety of the Æolic dialect.—The constant dissensions prevailing in Thessaly prevented it from occupying its rightful position in Greece. The inhabitants were early engaged in a constant war with the Phocians; they joined by constraint the army of Xerxes in his invasion of Greece, but took no part in the Peloponnesian war, though favoring on the whole the Athenians. In the latter half of the 4th century B. C. Jason, a man of great ability, gained the supreme power at Pheræ, and meditated not only the conquest of Greece, but the overthrow of the Persian empire. He succeeded in reducing all Thessaly to his authority, but before he had time to mature his designs, he was assassinated. The country subsequently fell into the hands of Philip of Macedon, and formed a part of the Macedonian monarchy until the defeat of Philip V. at Cynoscephalæ in 197 B. C., after which time it came under the Roman dominion, when the government was placed in the hands of the more wealthy persons, who used to meet in Larissa.—Thessaly now forms a part of the Turkish province of Saloniki (Salonica), and, though laid down on the maps as a separate district, is not recognized as such by the government. Its population is estimated at about 300,000, five sixths of whom are Greeks.

THETIS, in Greek mythology, a Nereid, the wife of Peleus, and the mother of Achilles. She dwelt in the depths of the sea with her father Nereus, and was sought in marriage by both Jupiter and Neptune; but the gods immediately relinquished their suit when it was declared by Themis that the son of Thetis should be more illustrious than his father.

THEVENOT, JEAN DE, a French traveller, born in Paris, June 6, 1633, died in Persia, Nov. 28, 1667. The wealth inherited from his father enabling him to gratify his taste for travel, he visited England, Holland, Germany, and Italy, and in 1655 departed for the East, by way of Sicily, Malta, and Constantinople, visiting and exploring Asia Minor, Egypt, and Tunis, and returning home, after 7 years' absence, in 1662. After preparing his *Voyage du Levant* (4to., Paris, 1664), he sailed again for the East, sojourned 5 months in Isfahan, examined the most famous remains of Persia, went to Surat in 1666, and for nearly one year travelled over the Indian peninsula. His health being impaired, he started on his return home by way of Persia, but died at Miana, a small place 90 miles S. of Tabriz. Until a few days before his death he kept a diary, from which his friends were enabled to publish his account of Persia, as a sequel to his *Voyage du*

Levant, and his still more important *Voyage contenant la relation de l'Indoustan, des nouveaux Mogols et des autres peuples et pays des Indes* (4to., 1684). His works were afterward collected under the title of *Voyages de M. Thévenot tant en Europe qu'en Asie et en Afrique* (5 vols. 12mo., Paris, 1689), and have been translated into Dutch, English, and German. He is said to have introduced coffee into Paris.

THIBAUT IV. or VI. as count of Champagne, I. as king of Navarre, a French *trouvère* or poet, born in 1201, died July 8, 1253. A posthumous son of Count Thibaut III. or V., he was educated at the court of Philip Augustus under the supervision of his mother, Blanche, daughter of Sancho the Wise, king of Navarre, and became an early adept of the "gay science." Several of his poems were addressed, under an assumed name, to Blanche of Castile, the queen of Louis VIII., whom he loved to distraction, although she was 14 years his senior. When her husband died prematurely at Montpensier in 1226, while returning from an expedition against the Albigenses, Thibaut, who accompanied him, was suspected, but on no plausible grounds, of being his poisoner. He soon after joined the league of feudal lords who rose against Blanche, then regent; but her influence brought him back to his duty to the king, and through his assistance she was enabled to baffle the designs of the confederates. In 1234, Sancho dying without male issue, the count of Champagne inherited the kingdom of Navarre in right of his mother. In 1289 he proceeded to the Holy Land; but he was unfortunate as a crusader, met with a dreadful defeat near Gaza, Sept. 18, 1240, and had to pay a heavy ransom for the release of his brother, who had been taken prisoner. His provinces were very prosperous under his government, and remains of edifices built by him are still found in Champagne; and he was a patron of literature and the fine arts. Although of a kindly disposition, he yielded to the religious opinions of his time, and allowed the Albigenses to be persecuted in his dominions; he even assisted, May 18, 1289, in the burning at the stake of 83 of those heretics, at Montrimier, near Vertus. He spent his latter years mostly in Navarre, and died there. Among his poems, 66 songs have been preserved and published by Lévesque de la Ravalhière (2 vols. 12mo., Paris, 1742; best edition by Rocquefort and Michel, Paris, 1829). Notwithstanding the obsolete language in which they are couched, their elegance and gracefulness are still remarkable.

THIBAUT, ANTON FRIEDRICH JUSTUS, a German jurist, born in Hameln, Hanover, Jan. 4, 1774, died in Heidelberg, March 28, 1840. He was educated at the universities of Göttingen, Königsberg, and Kiel, and in 1799 became professor of law in the last named university, and in 1802 in that of Jena. In 1805 he accepted a professorship in Heidelberg, and remained there until his death. In 1826 he was

made privy councillor of Baden, in 1830 knighted, and in 1834 made a judge in the tribunal of arbiters for the domestic affairs of Germany. His great work is his *System des Pandektenrechts* (2 vols. 8vo., Jena, 1808), which has passed through many editions. In 1814 he published a treatise "On the Necessity of a Common Code of Laws for Germany," in which he placed himself at the head of a movement designed to form one general code, as had been done in France, instead of the confused administration of the laws under the old German, the Roman, and the French codes which had hitherto prevailed. It was opposed by Savigny in a treatise "On the Aptitude of the Present Age for Legislation and Jurisprudence," in which he maintained that Germany was not yet ready for a common legislation. Among Thibaut's other works are: *Juristische Encyclopädie und Methodologie* (Altona, 1797); *Versuche über einzelne Theile der Theorie des Rechts* (2 vols., Jena, 1798); *Theorie der logischen Auslegung des Römischen Rechts*, (Altona, 1799); *Ueber Besitz und Verjährung* (Jena, 1802); and *Civilistische Abhandlungen* (Heidelberg, 1814). He also founded and was one of the editors of the *Archiv für civilistische Praxis* (Heidelberg, 1818 *et seq.*) and the *Heidelberger Jahrbücher*. As a musical critic he wrote *Ueber Reinheit der Tonkunst*, which brought him into a violent controversy with Nägeli of Zürich. His posthumous works on jurisprudence were published by Gurpet in 2 vols. (Berlin, 1841-'2).

THIBET, TIBET, or TUBET, a name given by Europeans to an extensive region of central Asia, called by the natives Bod or Bodyul, "Land of Bod," and by the Chinese Si-dzang, lying between lat. 27° and 36° N. and long. 78° and 104° E.; bounded N. by Chinese Toorkistan, E. by China, S. by Burmah and Hindostan, from which it is separated by the Himalaya chain, and W. by Khoondooz and Cashmere, formerly the dominions of Gholab Singh; area estimated at 698,000 sq. m.; pop. about 6,000,000. It forms the southernmost of the three great table lands of central Asia, and the Kuen-lun mountains on its northern boundary are the true watershed between the streams flowing into the Indian ocean and those into the lakes and seas of N. W. Asia. Thibet proper comprises two provinces, Eastern and Western Thibet, and belongs to the Chinese empire. Bultistan or Little Thibet, and Ladak or Middle Thibet, once forming part of it, are now tributary to Cashmere, and Bootan is partly independent and partly tributary to Thibet. The principal towns are Lassa or H'Lassa, the capital of Thibet and the sacred capital of all Buddhistic countries, a city in the same latitude with Cairo, Bassorah, Shanghai, and New Orleans, but with a climate almost as severe as that of St. Petersburg; Teshoo-Loomboo, the capital of Western Thibet, lying near the Sanpoo, a city of 20,000 inhabitants; Jega-Gungar and Shigatze, each with 100,000 inhabitants;

Tashigong, Gardikh or Gertopé on the Indus, Chaprung, Toling, Daba on the Sutlej, Bathan on the Kincha, and Tsiamdo on the Me-kiang. The Chinese viceroy resides at Teshoo-Loomboo.—Thibet has numerous lakes, the largest of which are Koko-nor and Tcharin-nor, near the sources of the Hoang-ho; Tengri-nor and Paltee, without outlets; Rhawan Rhad, 15,000 feet above the sea; and Mansarowar, at the source of the Sutlej. Nearly all of these lakes are brackish. The head waters of most of the great rivers of S. and S. E. Asia are within the limits of Thibet, as the Sutlej, the Indus, the Jumna, and 2 or 3 other affluents of the Ganges, the Brahmapootra, the Irrawaddy, the Salwen, the Hoang-ho, and the Yang-tee-kiang. The country is one of the most elevated on the globe, being surrounded by lofty mountain chains, and, though presenting a varied surface of hill and valley, seldom except in its lowest valleys less than 10,000 feet above the level of the sea, while the height of the greater part is 14,000 feet or more. The N. E. part of Thibet is a desert, cold and barren; branches of the Karakorum range, itself a branch of the Himalaya, traverse the country from W. to E., and the chain of Kuen-lun sends out its spurs in the E. The southern portion is less wild and alpine in character; and along the N. slope of the Himalaya, especially toward the W. part, are found fresh water pleistocene deposits. Generally, especially in the north, metamorphic rocks alternate with belts of granite. The soil is sterile except in the valleys. The climate in the higher districts is very cold and dry; timber never rots, but becomes so dry as to break from excessive brittleness; the flesh of animals exposed to the air dries till it can readily be reduced to powder, and is preserved for years in that condition, forming a common article of food. The limit of perpetual snow is higher on the Thibetan than on the Indian side of the Himalaya; a singular fact, which is attributed to the radiation from the sandy deserts. It varies from 16,600 to 18,000 feet above the sea, while in India it descends even below 13,000 feet, and under the equator it is usually between 15,000 and 16,000. The prevalent diseases are goitre, syphilis, ophthalmia, hydrophobia, and small pox. The mineral productions of Thibet are very abundant. Gold is found in nuggets and veins, and in the sands of several of the rivers. Silver, mercury, native cinnabar, lead, iron, and rock salt are found in mines; but the want of fuel prevents any very large production. Lapis lazuli, turquoises, sulphur, borax, and nitre are also abundant. There are numerous mineral and thermal springs. The vegetation is scanty; there are few forest trees; the cedar and birch are the principal trees of the mountainous districts, and in the valley of the Mouran the apple, fig, pomegranate, apricot, peach, vine, and several varieties of nuts flourish. Wheat and rice are cultivated sparingly, and some buckwheat, but gray or black barley is the

principal grain and the chief article of diet. The number of animals is greater than would be expected from the scantiness of vegetation; the wild cat, tiger, leopard, lynx, badger, and bear are the principal carnivora; the graminivorous animals of Europe are nearly all found there, and in addition the yak or grunting ox, the musk deer (both said to be aboriginal there), the elephant, wild ox, buffalo, goat, the argali with its horns weighing 100 lbs., and the bhoral or long-haired sheep. Wild fowl and fish are abundant, but Lamaism prohibits them as articles of food.—The inhabitants belong to the Mongol race, and were originally nomadic. They are pliant and agile, and usually brave, generous, frank, and honest. There are also some Bootanese and Katchi or Cashmerians, who are workers in metals and merchants. The practice of polyandry is common, one woman being the wife of all the brothers in a family. The Thibetans cultivate the soil wherever it is arable, but are not much skilled in agriculture. They are very ingenious workers in gold and silver and precious stones, and make very fine woollen cloths, shawls, &c., from their fine wool and the hair of the shawl goat. Sacking and other articles are also woven in considerable quantities for the Chinese market. Cloths are dyed with great skill, and the manufacture of pottery and of idols is a thriving trade. The traffic with China is considerable, amounting to about \$4,000,000 per annum. There is also a brisk trade with Nepal, Bootan, Bengal, Assam, and Cashmere. The two first named countries obtain all their Chinese goods through Thibet. The roads of Thibet are bad, and impede the commerce of the country greatly.—The language, which is common to Thibet and Bootan and hence called indifferently Thibetan or Bhotanta, is classed with the monosyllabic languages, though possessing some polysyllables. Its alphabet is phonetic, reads from left to right, and is evidently borrowed from the Sanscrit; the language however owes most of its derivatives and some of its root words to the Chinese. It is copious and well adapted for the expression of philosophical and religious ideas. There is an extensive literature, mainly composed however of translations and commentaries on the Buddhist sacred books. The religion of Thibet is the worship of the dalai or grand lama. (See LAMAISM.) There are some Mohammedans in Western Thibet, chiefly natives of Cashmere, and, according to M. Hue, about 8,000 Roman Catholics.—As a kingdom Thibet is said to date from A. D. 812. Buddhism was introduced in the 4th or 5th century. It became tributary to China in 1648, and the amount of the tribute was increased in 1724; but as the Chinese government renders homage to the dalai lama, and pays a sum for the support of his worship fully equal to that received as tribute, the amount paid by Thibet as a tributary nation is not of much importance. The Chinese government has its governors or repre-

representatives in most of the principal towns, and maintains a force of 60,000 soldiers in the country. The governors exert considerable influence over the Thibetan government, though it is professedly independent. The temporal as well as spiritual ruler is the dalai lama, but it is only in matters of the highest importance that he interferes. Most of the ordinary business of state is managed by his vicegerent, the *nomekhan*, and the four *kalons* or ministers, who are appointed by the grand lama for life. On the death of the grand lama the *khutukhtu* or grand council, composed of the highest lamas or priests, appoint his successor, or rather discover the body into which his soul has transmigrated. Some of the members of the *khutukhtu* are governors of the principalities into which the provinces are divided.—See Huc, "Recollections of a Journey to Tartary, Thibet, and China during the Years 1844-'6," translated from the French (New York, 1856); and Turner, "Embassy to the Court of Teshoo Lama in Thibet" (London, 1800). The forthcoming work of the brothers Schlegelintweit on the region of the Himalaya will contain much valuable information on Thibet.

THICK-KNEE, the common name of the wading birds of the plover family and subfamily *adinenmina*, peculiar to the old world. In the genus *adinenmus* (Temm.) the bill is about as long as the head, with straight culmen, depressed at the base and swelled at the apex, with the nostrils in a deep longitudinal groove on each side; wings moderate and pointed, 2d quill the longest; tail long and wedge-shaped; legs long, swollen about the knees, with bare part of tibiae and tarsi reticulated; anterior toes partly united by a web, and hind toe wanting. There are about half a dozen species, rearing their young in temperate regions and passing the winter in warmer attitudes, migrating at night and with great wiftness; they frequent dry and uncultivated places, hiding by day and feeding during twilight and at night on worms, slugs, insects, and small reptiles and mammals; they are quick runners and powerful fliers; the eggs are generally 2, laid in a slight hollow in the ground, and the young follow the mother as soon as hatched. The common thick-knee (*E. crepitans*, Temm.) is about 17 inches long and 2 feet in alar extent; the bill 2 inches, yellowish, black toward the point; head, neck, and upper parts pale tawny brown, with a dash of black down each shaft; under parts ashy, yellowish white on abdomen; a pale band above and below the eyes, and across the wings; quills black. It is abundant in Asia, Africa, and S. Europe, visiting Great Britain in summer, preferring sandy plains; it is called *corfolk* and great plover, and land or stone curlew, from the resemblance of its cry to that of the common curlew; the flesh of the young is said to be delicious; the eggs are ashy white, with olive brown blotches, and 2½ inches long. Other species are found in Africa, Australia,

and the East Indies. In the genus *caacus* (Less.) the bill is longer and stronger, curved upward at the tip, and the sides are angular at the base; they are found in the wide sandy banks of the large rivers of India during winter, migrating northward as summer advances; the food consists of crabs and other hard-shelled crustaceans. Species occur in the East Indian archipelago and in Australia. This sub-family seems to form the connecting link between the plovers and the bustards.

THIERRY, JACQUES NICOLAS AUGUSTIN, a French historian, born in Blois, May 10, 1795, died in Paris, May 28, 1856. After completing his collegiate studies at Blois, he entered the normal school at Paris in 1811, and in 1813 was appointed to a professorship in a departmental college. In 1814 he returned to Paris, became acquainted with St. Simon, and acted as his amanuensis; he even styled himself his "adoptive son" upon the title page of one of their joint productions; but, being indisposed to sanction all the socialistic views of his master, he left him in 1817, and became a contributor to the *Censeur Européen*, in which he published a "View of the English Revolutions," an outline sketch of one of his future great works, and several other essays, mostly upon the history or literature of England. In 1820, the publication of the *Censeur Européen* having ceased, he connected himself with the *Courrier Français*, to which he contributed *Deux lettres sur l'histoire de France*. In the beginning of 1821 he exclusively devoted himself to the composition of a work which was to be the embodiment of his new theory of writing history. After 5 years' incessant labor, his *Histoire de la conquête de l'Angleterre par les Normands* appeared (8 vols. 8vo., 1825), the success of which was unparalleled, but dearly paid for; his sight had been impaired to such a degree that he was henceforth unable to read or write. Vainly did he try to recover it by rest and travel; one year later he was entirely blind. Nothing daunted by this misfortune, he resumed his wonted pursuits with the assistance of a secretary, first employing in that capacity Armand Carrel, afterward so celebrated as a journalist. In 1827 he published his *Lettres sur l'histoire de France*, which, beside the 10 letters that had previously appeared in the *Courrier Français*, comprised 15 new ones, presenting a most graphic picture of the establishment of communes in France. In 1829 he was elected a member of the academy of inscriptions. A nervous disease now preyed upon him, and while at the baths of Luxeuil in 1831 he made the acquaintance of Mlle. Julie de Querangal, a young lady of literary attainments, who became his wife. Through her help and that of a secretary, he produced, from 1831 to 1835, a series of narratives from the history of France in the 6th century, republished under the title of *Récits des temps Mérovingiens, précédés des considérations sur l'histoire de France* (2 vols. 8vo., Paris, 1840), which

was considered to fully justify the name *Homère de l'histoire* previously bestowed upon him by Châteaubriand, and for which he received during 15 years the Gobert prize for the most important historical work. Meanwhile he had reprinted, under the title of *Dix ans d'études historiques* (8vo., 1834), with a prefatory sketch of his historical views and performances, such of his papers as had appeared from 1817 to 1827 in various periodicals, and were not incorporated in his other works. In 1835 he was intrusted by M. Guizot, minister of public instruction, with the direction and control of the large publication entitled *Documents inédits de l'histoire du tiers état*, as an introduction to the first volume of which he wrote an *Essai sur l'histoire de la formation et des progrès du tiers état*, which was separately reprinted in 1853, and is, as the author himself expressed it, the "summing up of all his researches upon the history of France." His works have been reprinted many times; the best editions are the last, issued under the supervision of their author (5 vols. 8vo. and 10 vols. 12mo., Paris, 1854). The most important have been translated into English and German.—AMÉDÉE SIMON DOMINIQUE, brother of the preceding, born in Blois, Aug. 2, 1797, is also a distinguished historian. His *Histoire des Gaulois* (3 vols. 8vo., Paris, 1828) was a valuable addition to historical literature. During the reign of Louis Philippe he became prefect of Haute-Saône and master of requests in the council of state; and while fulfilling his official duties, he published the *Histoire de la Gaule sous la domination Romaine* (2 vols. 8vo., 1840-'42), a sequel to his first work. In 1851 he returned to his historical pursuits, with which he is still occupied. His *Histoire d'Attila, de ses fils et de ses successeurs* (2 vols. 8vo., 1856) is full of curious information. He is now (1862) publishing in the *Revue des deux mondes* a new series of historical papers entitled *Trois ministres de l'empire Romain sous les fils de Théodose, Rufin, Eutrope et Stilicon*.

THIERS, LOUIS ADOLPHE, a French historian and statesman, born in Marseilles, April 16, 1797. The son of a poor workman, through the patronage of some influential relations he was admitted to the college of his native town, afterward studied law at Aix, where he became acquainted with M. Mignet, and was graduated in 1820, but instead of following the profession devoted his attention to history and philosophy. After winning a prize at the academy of Marseilles for his panegyric of Vauvenargues, he went to Paris with Mignet in Sept. 1821, and two months later, through Laffitte's patronage, became a contributor to the *Constitutionnel*. His quick perception and versatility, ready wit and sprightliness of style, boldness of attack and ability as a controversialist, admirably fitted him for the daily labor of a journalist, and he soon reached a leading position. A shrewd political writer and literary critic, he proved also a skillful judge of the fine arts in his *Salon de 1822* (8vo.,

Paris, 1822), and an elegant tourist in *La Pyrénées* (8vo., 1823). Through activity and skilful management, he now found himself in easy circumstances, while, in spite of his awkward manners and strong provincial accent, he was the welcome guest of Laffitte and other leaders of the opposition. He profited by his intercourse with many of the most eminent men of the preceding generation to gather information upon the French revolution, the history of which he had undertaken in connection with Félix Bodin; the first two volumes appeared in 1823, and the work was completed by Thiers alone 4 years later in 10 volumes. This *Histoire de la révolution Française depuis 1789 jusqu'au 18 Brumaire*, bitterly denounced by the royalists, but highly appreciated by eye-witnesses of the events, won great popularity with the public at large, and has passed through more than 15 editions. On the accession of Prince Polignac to the ministry, Aug. 5, 1829, M. Thiers, dissatisfied with the moderate politics of the *Constitutionnel*, established, in conjunction with his friends Mignet and Armand Carrel, a new political journal, the *National*, which more than any other contributed toward bringing about the revolution of 1830. On the appearance of the royal decrees of July 26, the editors of the *National* were among the first who signed the protest of the Parisian journalists; and Thiers was foremost in proposing and supporting the elevation of the duke of Orleans, first to the regency, Aug. 1, then to the throne, Aug. 9. Three months later he was appointed assistant secretary in the department of finance, first under Baron Louis, then under Laffitte. He had been at the same time elected by the city of Aix to the chamber of deputies, where he was at first laughed at as a speaker; his bombastic style of oratory, connected with his short stature and shrill voice, made him ridiculous, and it was only after altering his style and subduing his tone that his talents as an expounder of the most intricate questions were appreciated. On the fall of Laffitte, March 13, 1831, he resigned his office; but instead of following the example of his patron, who had gone over to the opposition, he sat among the supporters of Casimir Périer, and advocated the peace policy, a hereditary peership, and several other measures that were unpalatable to the people. On the insurrection of June 5 and 6, 1832, he insisted upon the necessity of dealing severely with the republicans and the legitimists. This ingratiated him with the majority of the deputies and the court; and therefore, on the death of Casimir Périer, he became minister of the interior, Oct. 11. He succeeded, by bribing the treacherous Dentz, in arresting the duchess of Berry and suppressing the impending war in Vendée, and advised the expedition against Antwerp, which proved successful. Being transferred to the ministry of commerce and public works, he obtained a grant of 100,000,000 francs from the chamber of deputies, and

gave a new impulse to internal improvements; the statue of Napoleon was placed again on the top of the column of Vendôme; the triumphal Arc de l'Étoile, the Madeleine church, and other monuments were completed or erected; canals and railroads were constructed, and under the fostering care of the administration industry revived. In 1834, on the prospect of political troubles, he resumed the ministry of the interior, and evinced personal courage in putting down the insurrectionary movements of April 12 and 18. He resigned Nov. 11; but after a succession of unfortunate ministerial combinations, he resumed his post, with Guizot as his colleague, under the premiership of the duke de Broglie. He had a narrow escape from the murderous attempt of Fieschi, July 28, 1835, and unreservedly advocated the adoption of the so called "laws of September," severely restricting the freedom of the press and the jury. New intrigues occurred in 1836; the whole cabinet sent in their resignation; but Thiers, who had secretly paved his own way, rose to the premiership, holding at the same time the ministry of foreign affairs, Feb. 22. Being however unable to persuade the king to adopt a more liberal policy at home and to show more energy in his transactions abroad, he retired, Aug. 25, and was succeeded by M. Molé. As one of the leaders of the opposition, he adhered in 1838 to the coalition which finally overthrew that minister, and was reinstated in his former position, March 1, 1840. This was the most trying period of his ministerial career; his home policy was impeded by the undecided character of the chamber of deputies; he had to maintain the September laws and retard electoral reform. In his foreign policy he was entirely outwitted by the diplomatists of Russia, England, and Austria, who had agreed to settle the eastern question without consulting France. Enraged at this consummation, and convinced that war only could again raise his country to its proper standing, he was fearlessly preparing for such an emergency, reënforcing the regular army, getting the national guards in readiness, and constructing the fortifications of Paris; but at the last he could not prevail upon the king to resort to such desperate means, and therefore, after 6 months of useless exertions and bitter disappointments, he resigned his powerless premiership, Oct. 29, being succeeded by M. Guizot, and thenceforth was never more recalled to the control of public affairs. He figured as one of the opposition leaders, bitterly censuring the policy of the Guizot cabinet in 1844, denouncing the growing influence of the order of Jesuits in 1845, and insisting upon the necessity of excluding public functionaries from the chamber of deputies in March, 1846. His powers never shone more brilliantly than during the latter part of Louis Philippe's reign; and his vehement speeches against M. Guizot's policy were extensively read and eagerly commented upon, while the articles he contributed

to the *Constitutionnel*, in the ownership of which he had now a share, spread far and wide the so called "reformist agitation." But, like so many others, he was taken unawares by the revolution of Feb. 1848. He vainly attempted to retrieve the falling fortunes of the king; he was powerless to check the progress of the republicans; and when their triumph was an established fact, he adhered to the new government. He appeared as a candidate for the constituent assembly, and failed, in the general election, but was on June 4 returned by 4 departments; he sat for that of Seine-Inférieure, voted for placing dictatorial powers in the hands of Gen. Cavaignac, proved himself in his speeches and pamphlets an unmitigated opponent of socialism, was one of the leaders of the so called "order party," and, after evincing little partiality for Louis Bonaparte, finally voted to make him president. A deputy in the legislative assembly and a member of the *club de la rue de Poitiers*, he aimed at overthrowing the republic and bringing about a monarchical restoration; but he and his friends were superseded by the superior cunning of President Bonaparte. On the morning of Dec. 2, 1851, he was arrested at his house, confined to prison for a while, and then transported to Frankfort-on-the-Main. A few months later he was allowed to return, but gave up active politics, and resumed his historical pursuits. As early as 1845 he had published the 1st volume of his *Histoire du consulat et de l'empire*, and had reached the 9th previous to the revolution of February. This work, which gives the fullest account of European affairs from 1800 to 1815, he now hastened, issuing one or two volumes every year; the 20th and last volume is yet to be published. An extraordinary prize of 20,000 francs has been recently awarded to it by the French institute. M. Thiers is a member of the French academy and of the academy of moral and political sciences. Beside his two great historical works, he has published several political pamphlets and an able essay upon *Lavo et son système de finances* (8vo., Paris, 1826; new ed., 12mo., 1858). He is reported to have in preparation a "History of Florence." His biography has been written by Alexandre Laya: *Études historiques sur la vie privée, politique et littéraire de M. A. Thiers* (2 vols. 8vo., 1846).

THIERSCH, FRIEDRICH WILHELM, a German scholar, born at Kirscheidungen, June 17, 1784, died in Munich, Feb. 25, 1860. He followed the courses in theology and philology at Leipzig, and studied under Heyne at Göttingen, where he received a degree in 1808, and became a teacher in the gymnasium. He displayed remarkable talent as an instructor, and was called in 1809 to a professorship in the newly established gymnasium at Munich. He and Jacobi were among the first from northern Germany to receive royal appointments at Munich; and during the excitement raised by Christoph von Arétin he published a pamphlet entitled

Unterschied zwischen Nord- und Süddeutschland, which so increased the popular jealousy that an attempt was made to assassinate him. He established in 1812 a philological institute, afterward united with the university, and edited the *Acta Philologorum Monacensium* (8 vols., Munich, 1811-'21). In 1818 he urged the war against France, aided the military organization of the students, and also became an enthusiastic Philhellenist. He visited France and England, was sent as a commissioner from Bavaria to demand the restoration of the objects of art which had been taken from it, met Capo d'Istria at Vienna (1814), and, without sharing in his political designs, sought to found a scientific union for the education of young Greeks. After the triumph of the Hellenic cause he travelled in Greece, and was influential in disposing the country to accept a monarch from Germany. He published on his return a work entitled *De l'état actuel de la Grèce, et des moyens d'arriver à sa restauration* (2 vols., Leipzig, 1838), a eulogy on the modern Greeks. He had previously produced a grammar of the Homeric dialect (8d ed., 1826), an annotated edition of Pindar, containing metrical translations (3 vols., 1820), a treatise on the epochs of sculpture among the Greeks (2d ed., 1829), and a narrative of travel in Italy (1826). From this time he was chiefly occupied in carrying out the educational plans which he had already suggested. Commissioned to investigate the state of the gymnasia of Germany, he published reports (8 vols., 1826-'37), in which he urged adherence to the classical discipline, against the partisans of so called real schools which combined classical with professional or mercantile studies. A long controversy ensued, in which he produced other works in defence and illustration of his system, which was maintained in Bavaria with slight modifications till 1858.—His brother BERNHARD (died Sept. 1, 1855) was the author of a work on the age and country of Homer (2d ed., 1832), and a collaborator on Ranke's learned edition of Aristophanes (1830).

THILO, JOHANN KARL, a German theologian, born at Langensalza, Nov. 28, 1794, died May 12, 1858. He studied theology at the universities of Leipzig and Halle, was appointed in 1817 teacher at the orphan house, and soon after at the *Padagogium* of Halle, and while in this position assisted Professor Knapp, his father-in-law, in the direction of the theological seminary. In 1820 he made with Gesenius a journey through France and England. In 1822 he was appointed extraordinary, and in 1825 ordinary professor of theology; and in 1833 he was made consistorial councillor. He won a high reputation by his *Codex Apocryphus Novi Testamenti* (vol. i., 1832), which surpassed all previous works on this branch of theological literature in critical acumen and correctness. Beside several other smaller works, he also edited Knapp's *Vorlesungen über die christliche Glaubenslehre* (2 vols., 2d ed., 1836).

THIMBLE (perhaps from thumb and bell), a metal cap for the finger, used in sewing to protect it from the needle. It is said to be of Dutch invention, brought to England about the year 1695 by John Lofting, who set up a workshop at Islington near London, and made thimbles with profit and success in different metals. For the use of men the thimble is commonly made without a top in the form of a wide ring, indented upon its surface with numerous small pits to catch the head of the needle. Those provided with a top are similarly indented upon this portion also. Thimbles are made of thin sheets of different metals, brought into shape by punching disks of the plate into dies. Brass was formerly a common material, which has given place to silver, and of late years gold thimbles or thimbles coated with gold have been largely used. The process of Messrs. Roux and Berthier of Paris is much recommended as making thimbles of great perfection and durability. Thin sheets of sheet iron are cut into disks of about 2 inches diameter, which being heated to redness are struck with a punch into a succession of holes of gradually increasing depth to give them the form of thimbles. The metal is then trimmed, polished, and indented with little holes regularly distributed by means of a double-toothed wheel rolled around its surface. It is next converted into steel by the cementation process, tempered, secured, brought to a blue color, and lined with a very thin sheet of gold, which is forced in with a polished steel mandrel, which causes it to fasten to the steel as if it were soldered. Gold leaf is then applied to the outside, and is attached by pressure, the edges being secured in a minute groove made to receive them. When made of one metal only, thimbles are more rapidly produced by striking the plate into a succession of conical dies, annealing them with each successive one.

THIMBLEBERRY. See RASPBERRY.

THIONVILLE, a city of the department of Moselle, France, situated on the Moselle, about 17 m. above Metz; pop. in 1856, 10,500, beside a garrison of 2,000 men. It is connected with Metz by a railroad, and with Luxemburg and other towns by excellent roads. It has a large trade in timber and firewood, coal and coke, grain, and iron. Coal to the amount of 20,000 tons per annum is shipped from the town. About 150,000 quintals of grain and considerable quantities of leather and cut stone are exported. The iron forges and furnaces in the vicinity produce iron to the value of more than \$2,400,000 annually. Some of these furnaces have been in operation since the 14th century. They produced good wrought iron by the use of mineral coal in 1823, an earlier date than any other furnaces in France attempted it.

THIRD ESTATE. See TIERS ÉTAT.

THIRLWALL, CONNOP, D.D., an English historian and prelate, born at Stepney, Middlesex, in 1797. The son of the rector of Bow-

ers Gifford, Essex, he was educated at Trinity college, Cambridge, was tutor, Craven scholar, Bell's scholar, and senior chancellor's medalist, received the degree of bachelor in 1818 and of master in 1821, and became a fellow. He studied law, and was called to the bar at Lincoln's Inn in 1825, but after 8 years' experience withdrew from the profession, entered the church, and became rector of Kirby-under-Dale, Yorkshire. He joined with J. O. Hare in translating the first two volumes of Niebuhr's "History of Rome" (1828), and contributed to Lardner's "Cabinet Cyclopædia", a history of Greece (1835 *et seq.*), enlarged and improved in a subsequent edition (8 vols., 1845-'53). This work was the basis of a manual by Dr. Schmitz, in the introduction to which he classes it with the later production of Grote as "two English works on the history of Greece such as no other nation can boast of." Another critic says: "It is impossible not to miss in the marble coldness of the bishop of St. David's something of the animating warmth which his predecessor (Miford) derived from his practical life as an English country gentleman; while, on the other hand, every one recognizes the abundant stores of knowledge and the tact of finished erudition with which the Cambridge scholar was so largely gifted, and which to the Hampshire squire were almost entirely denied." He was for several years examiner for the classical tripos in Trinity college, and examiner in the university of London, and is now visitor of St. David's college, Lampeter. In 1840 he received the degree of D.D., and was created bishop of St. David's. He has published separately a few sermons and charges.

THIRST, the familiar sensation by which the want of fluid in the system is made known, dependent on the condition of the stomach, throat, and fauces, and in a state of health a tolerably faithful indication of the requirements of the body. It becomes, therefore, the stimulus to the mental operations and acts having for their object the gratification of the desire; in infancy these actions are automatic and involuntary. It is generally considered as immediately resulting from an impression on the nerves of the stomach, as it is allayed by the introduction of liquids through a tube, so that the fauces are not touched; in this way speedy relief is obtained from the instantaneous absorption of the fluid by the veins of the stomach. This, however, must be taken with some qualification, as the intensity of thirst bears no necessary relation to the amount of liquid in the stomach, but indicates a want of the system which can be supplied through the blood vessels, the rectum, or the skin; in fact, the conditions are very analogous to those mentioned under HUNGER, both indicating a demand in the system to be supplied through the stomach, which in the case of thirst is indicated locally in the throat and fauces. According to Bostock, it is immediately produced by a deficiency of the mucous

secretion of the throat and fauces, ultimately depending on a peculiar condition of these mucous glands. A supply of fluid, as indicated by thirst, is necessary to make up for the losses by cutaneous and pulmonary exhalation, and by the urinary and other secretions, which are effected chiefly at the expense of the water in the blood, requiring a constant supply of new fluid. Water is the natural drink of man and beast, and the purer it is the better it supplies the wants of the system; the morbid influences of a very minute impregnation with lead and other soluble mineral poisons, of a trifling excess of saline ingredients innocuous in small quantities, and of putrescent matters in the water used for daily drink, are well known to physicians and toxicologists. Alcoholic mixtures cannot supply the wants of the blood except by their contained water, and antagonize many of the purposes for which water is required. Thirst is also allayed by tea and coffee, making up in a measure for insufficient food by lessening the waste of the nitrogenized tissues. Thirst is greatest in a dry and hot air, when the perspiration and other secretions are excessive; salted or highly spiced food, strong fermented liquors, and irritating substances and poisons applied to the intestinal mucous membrane, excite thirst, no doubt to induce an ingestion of fluid by which they may be diluted. A sudden loss of blood, either by the lancet or from a wound, or a rapid drain on the vascular system, as in Asiatic cholera, diabetes, and some forms of ascites, causes thirst in proportion to its amount. Thirst is less when the food is watery, and when liquid can be absorbed by the skin from the surrounding air or water. The thirst of fever does not necessarily indicate a pressing demand for fluids, but depends on the dryness and heat of the throat, mouth, and skin, with diminished transpiration, and is better relieved by small pieces of ice than by copious draughts of water. Any water ingested more than thirst demands does not of necessity increase the aqueous constituent of the blood, the superfluous fluid being carried off by the kidneys; and moreover, absorption from the stomach is diminished when the demand is satisfied. Animals with naked skins, like batrachians, living in water or moist air, have no need to drink to quench thirst, cutaneous absorption supplying the necessary fluid; thirst can hardly be felt by the rabbit, Guinea pig, and sheep, judging from the water they consume, on account of the amount of liquids in their fresh vegetable food; carnivorous mammals drink little, and rapacious birds hardly at all, the blood of their victims allaying their thirst; the camel supports thirst for a long time, carrying a supply of fluid in the water stomach; the amount of drink taken by man depends much on habit, and more on the nature of his food, the thirst of vegetarians being generally less than that of meat eaters. The sufferings from thirst in shipwrecked sailors and in travellers in the African and Ameri-

can deserts are familiar to all readers, as also the partial relief by moisture of the air and immersion of the body in salt water; they are more painful to bear than those of hunger, as is shown by the history of besieged garrisons and of persons who have attempted suicide by starvation. One of the most remarkable instances of suffering from thirst was in the case of the French frigate *Medusa*, lost in 1816 near the coast of Africa; of 150 persons who took refuge on a raft without food or water, 15 only survived after 18 days of intense suffering; while their hunger had become almost nothing on the 9th day, their thirst was inextinguishable, to such a degree that they drank urine; and to render their sufferings more exquisite, during their feverish sleep they dreamed of cooling shade and running brooks, to awake to a tropical sun and a briny ocean. The raging thirst of the victims of the black hole of Calcutta is another familiar instance of similar suffering. In extreme thirst, with dryness and inflammation of the fauces and throat, the perspiration, urine, and faeces are diminished, and finally suppressed; the muscular debility becomes greater and greater, soon followed by delirium, coma, and death. Abstinence from both food and drink is generally fatal in a week; hunger alone may be sustained for 6 or 7 weeks, but thirst alone for a less period. The intense thirst of Asiatic cholera has been relieved by injections of saline matters into the blood.

THISBE. See PYRAMUS AND THISBE.

THISTED, WALDEMAR ADOLF, a Danish author, known under the assumed name of Emmanuel de Saint-Hermidad, born in Aarhus, Feb. 28, 1815. He studied theology at Copenhagen, in 1840 founded a school at Skanderborg, which he directed until 1844, and in 1846, after a journey in Germany and Switzerland, became a teacher in the high school of his native place. During 1849-'50 he travelled in Germany and Italy. His travels, novels, and poems embrace some 15 volumes.

THISTLE, the common name of several genera of spiny plants of the natural order *compositæ*. The thistles are distinguished by the peculiarities of their florets, and by the differences in their downy pappus, as well as by the forms of their styles or pistils. The genus *carduus* with the older botanists included all plants with spiny involucre, but as it now stands comprises about 80 species, most of which are natives of Europe. A species known as the musk thistle (*C. nutans*) has spiny leaves and handsome drooping flowers, and is a common plant in dry chalky soils of Europe; toward evening a musky odor arises from the plant. The *C. personata* (cut-leaved thistle) is said to have derived its specific title from its large leaves being used for masks. The milk thistle (*C. Marianus*) has very spiny-margined leaves, beautifully variegated with white stripes or lines; the flowers are of a dull purple. It is frequently cultivated for its singularity and its milky ap-

pearance, attributed to the Virgin Mary as she is represented in an ecclesiastical legend.—The thistles of the United States are chiefly different species of *cirsium*, in all about 20, distinguished generically by perfect and similar, rarely subdiacous flowers, bristly receptacles, regularly or else unequally 5-cleft corolla of a purple, reddish, or else ochroleucous color, oblong, compressed, smooth, not ribbed achenia, and a plumose pappus. The common thistle (*cirsium lanceolatum*, Scopoli) came from Europe, and yet is too abundant by our roadsides and in rich pastures. It has a branching, somewhat hairy stem, very prickly decurrent stem leaves, smooth above, hairy and webbed beneath, and numerous handsome purplish flowers. The tall thistle (*C. discolor*) is very slender, 5 to 6 feet high; leaves sessile, pinnatifid, hairy, white and cottony beneath; flowers numerous and small, purple. The pasture thistle (*C. pumilum*, Sprengel) has a short hairy stem, green clasping leaves, oblong lanceolate and pinnated, the segments ciliated and spiny; the flowers few, large, purple, and sweet-scented. The Canada thistle (*C. arvensis*, Scop.) is a native of Europe, and in cultivated soils has extended through the United States and overrun the wheat fields of Canada. It is considered the greatest pest in the fields, and can only be subdued by ploughing up and patiently extracting its viviparous subterranean roots. The yellow or horrid thistle (*C. horridulum*, Michaux) is a tall, rough, disagreeable plant, with large, axillary, and terminal flower heads of yellow florets; it grows best very near the sea coast.—The cotton thistle (*opopordon acanthium*, Linn.) has become naturalized in New England, though adventitious from Europe. It is a tall, stout, and very showy plant, with large, decurrent, spiny, and downy whitish leaves, and large, light, purple flowers appearing in July. The blessed thistle belongs to a very extensive genus, and is the *cirsium benedictus* of Linnaeus, introducing itself into Louisiana, though native to the Levant.—Many plants bear the name of thistle belonging to quite distinct families. The thistles are regarded as weeds, and are eradicated only by perseverance and industry. Their seeds are eagerly sought for by birds of the sparrow tribes.

THISTLE, ORDER OF THE, a Scottish order of knighthood, reputed on very insufficient grounds to be of great antiquity, but which Sir Harris Nicolas is of the opinion had no existence as an organized fraternity previous to 1687, when a warrant for its restitution was issued by James VII. of Scotland and II. of England. It fell into abeyance after the abdication of James, but was restored by Anne in 1703, and is now one of the recognized orders of the British empire. The warrant of 1687 confined the number of knights to 12, beside the sovereign; but since May, 1827, it has been permanently extended to 16. It was formerly customary to admit none but Scottish peers into the order, but the rule is not now strictly

observed. The principal decorations are a gold collar, composed of 16 thistles interlaced with sprigs of rue, to which is suspended a small image of St. Andrew and a St. Andrew's cross of silver, in the centre of which is a thistle surrounded by the motto of the order (which is also that of Scotland): *Nemo me impune lacessit*, and from which emanate silver rays forming a star.

THOLUCK, FRIEDRICH AUGUST, D.D., a German divine and pulpit orator, born in Breslau, March 30, 1799. Descended from very humble parentage, he first learned a trade, but by the assistance of friends attended the gymnasium of his native city and the university of Berlin. When he left college he delivered a eulogy on Mohammedanism as equal in beauty and merit to the Christian religion; but during his university course he was thoroughly converted from his pantheism and scepticism under the influence of the lectures of Schleiermacher and Neander, and more especially by personal intercourse with Baron von Kottwitz, a member of the Moravian brotherhood. In 1821 he was graduated as licentiate of theology, and began to deliver lectures as *Privat-docent*. In 1824 he was appointed extraordinary professor of oriental literature, in the place of Dr. De Wette, in 1825 made a literary journey to Holland and England, and in 1826 was called to the university of Halle as ordinary professor of theology, in the place of Dr. Knapp. There he has lived and labored ever since, with the exception of a short residence at Rome in 1828-'9, in the capacity of chaplain to the Prussian embassy. He is also university chaplain and consistorial councillor. He had at first to suffer a good deal of persecution from the prevailing rationalism of his colleagues, but succeeded in effecting a radical change, the whole theological faculty of Halle now being decidedly evangelical. Dr. Tholuck is perhaps of all contemporary German divines the most fertile author. His principal works are as follows: "Sin and Redemption, or the True Consecration of the Sceptic" (Berlin, 1825, many times reprinted; translated into English by Ryland, with an introduction by John Pye Smith, republished in Boston, 1856), in opposition to De Wette's "Theodore, or the Consecration of the Sceptic" (1825); *Blüthen-sammlung aus der morgenländischen Mystik* (1825), a collection of translations from the mystic poets of the East; "Commentary on the Epistle to the Romans" (4th ed., 1842; twice translated into English), the first exegetical fruit of the new evangelical theology; "Commentary on the Gospel of John" (1826; 7th ed., 1857; translated into English by Kaufman, 1836, and by Dr. C. P. Krauth, Philadelphia, 1859), less thorough and permanent, but more popular and better adapted for students, than his other commentaries; "Commentary on the Sermon on the Mount" (1833; 8d ed., 1844; translated into English by R. L. Brown, Edinburgh, 1860), his most learned, elaborate, and valu-

able exegetical production; "Commentary on the Hebrews" (1836; 8d ed., 1850); "Commentary on the Psalms" (1843; translated into English, Philadelphia, 1859); "The Credibility of the Gospel History" (1837; 2d ed., 1838), a vindication of the Gospels against the mythical theory of Strauss; and "Hours of Christian Devotion" (2 vols., 1840), containing several original hymns. He has published several volumes of sermons since 1829, and two volumes of "Miscellaneous Essays" (1839). He is now (1862) engaged upon a "History of Rationalism." Several small volumes have appeared (1852, '54, and '61) on the preparatory history, in which he gives, mostly from manuscript sources, an account of the condition of Lutheran theology and German university life during the 17th century.

THOM, JAMES, a Scottish sculptor, born in Ayrshire in 1799, died in New York, April 17, 1850. He was brought up to the trade of a stone cutter, and first showed his talent for sculpture by the production of a head of Burns and some portrait busts, which gained him considerable local celebrity. These were followed by his well known group of "Tam O'Shanter," carved out of the common gray stone used for building purposes. Of this group and that of "Old Mortality," which is now deposited in the Laurel Hill cemetery, near Philadelphia, he was employed to make many duplicates, and both works were widely exhibited in Great Britain and the United States. In 1836 he removed to the United States, and settled in Orange co., N. Y.

THOM, WILLIAM, a Scottish poet, born in Aberdeen in 1799, died in Dundee in March, 1850. He was apprenticed at an early age to a weaver, and throughout life followed that occupation, dying at last in extreme need. He did not attempt composition until near the age of 40, and his earliest strains were extorted by the contemplation of his own poverty and by grief at the death of his wife. Rising soon after into some celebrity, he was brought to London, and complimented by his countrymen with a public dinner. Unfortunately no more substantial testimonial followed this ovation. In 1844 appeared his "Rhymes and Recollections of a Handloom Weaver," which met with but a moderate success.

THOMANDER, JOHAN HENRIK, a Swedish theologian, born in the province of Scania, June 16, 1798. He studied theology at the university of Lund, and was appointed in 1819 teacher at the school of Karlshamm, in 1821 pastor of the same place, in 1827 lecturer on theology at the theological seminary at Lund, in 1833 professor of pastoral theology, and in 1838 member of a committee for drafting a new code of church laws. In 1840 he was elected a representative of the clergy in the Swedish diet, in which he soon distinguished himself as one of the most brilliant speakers of the liberal party. In 1850 he was made provost of the cathedral of Gothenburg, and in

1856 bishop of Lund. He commenced his literary career with translations from Shakespeare, of the "Clouds" of Aristophanes, and of Byron's "Manfred" (Upsal, 1826). His theological works comprise "Hymns of the Ancient Church" (Stockholm, 1828); two collections of sermons (Malmö, 1829, and Lund, 1849); "The New Testament" (Örebro, 1835); and a "Catechism" (Lund, 1838). In connection with Reuterdaahl (since 1856 archbishop of Upsal) he edited from 1828 to 1832 a *Theologisk Quartalskrift*, of which in 1836 he became the sole editor. In 1859 he presided over the second Scandinavian church diet at Lund. He is regarded as one of the greatest Scandinavian pulpit orators.

THOMAS, a S. W. county of Georgia, bordering on Florida, and drained by the Ocklockonee river and its head streams; area, 920 sq. m.; pop. in 1860, 10,767, of whom 6,245 were slaves. The surface is level and the soil fertile. The productions in 1850 were 358,920 bushels of Indian corn, 146,022 of sweet potatoes, and 7,667 bales of cotton. There were 16 churches, and 376 pupils attending public schools. Capital, Thomasville.

THOMAS, ANTOINE LÉONARD, a French author, born at Clermont-Ferrand, Oct. 1, 1782, died at Oullins, near Lyons, Sept. 17, 1786. He was educated at Paris, and studied law, but early became a professor in the Beauvais college. In 1759 his poem *Jumôneille* attracted some attention; while his *Éloge du maréchal comte de Saxe* won the prize of eloquence at the French academy. The same distinction was awarded to his panegyrics of D'Aguesseau (1760), Duguay-Trouin (1761), Sully (1768), and Descartes (1766); and the prize of poetry to his *Ode sur le temps* (1762). He was elected a member of the academy in 1766, and in 1770 read before it his *Éloge de Marc-Aurèle*, considered his masterpiece, but not published till 1775. His *Essai sur le caractère, les mœurs et l'esprit des femmes dans tous les siècles* (1772) was coldly received, but was translated into several languages. His most important work, at once historical and critical, is his *Essai sur les éloges* (1778). His complete works have been published twice (7 vols. 8vo., Paris, 1802, and 6 vols. 8vo., 1825).

THOMAS, CHRISTIANS OF ST. See CHRISTIANS OF ST. THOMAS.

THOMAS, FREDERICK WILLIAM, an American author, born in Providence, R. I., Oct. 25, 1808. At the age of 17 he began the study of law, and after his admission to the bar removed to Cincinnati. He is the author of novels entitled "Olinton Bradshaw" (2 vols. 12mo., Philadelphia, 1835), "East and West" (2 vols. 12mo., Philadelphia, 1836), and "Howard Pinckney" (1840); of "John Randolph of Roanoke, and other Sketches of Character" (12mo., Philadelphia, 1838), &c. He has also published a poem entitled "The Emigrant" (Cincinnati, 1833), and "The Beechen Tree and other Poems" (New York, 1844).

THOMAS, ISAIAH, LL.D., an American printer, born in Boston in 1749, died in Worcester, Mass., April 4, 1831. Having served an apprenticeship of 11 years, he commenced business as a printer in Newburyport in 1767. In 1770 he removed to Boston and commenced the publication of the "Massachusetts Spy," in which he attacked with great boldness the oppressive measures of the British government toward the colonies. In 1771 Gov. Hutchinson ordered him to appear before the council in consequence of an article in his paper; he refused to go, and the attorney-general unsuccessfully attempted to obtain a bill of indictment against him from the grand jury; the governor then directed that officer to file an information against him, but such resistance was made to the measure that it was dropped. In 1775 Mr. Thomas took an active part in the skirmish at Lexington, and on May 8 commenced issuing his paper from Worcester, to which town he had removed. In 1788 he opened a bookstore in Boston, under the firm of Thomas and Andrews, and soon after established branches of his publishing business in various parts of the United States, though he continued to make Worcester his residence. In 1791 he printed an edition of the Bible in folio, and subsequently issued numerous editions of smaller size. For many years most of the school books of the country were printed and published by him. In 1810 he published his "History of Printing in America" (3 vols. 8vo.). The American antiquarian society of Worcester was founded through his efforts in 1812, and liberally endowed by him. He received the degree of LL.D. from Allegheny college, Penn., for his services to literature.

THOMAS, SAINT, also called Didymus, one of the twelve apostles. Both names, the Hebrew Thomas (Th'om) and the Greek Didymus, denote a twin. Of the history of Thomas very little is known, as he is but rarely mentioned in the Scriptures. When Jesus after his crucifixion appeared to his disciples, Thomas was not present, and he refused to believe the occurrence until he himself saw and touched Jesus. As to the scene of his apostolical labors, the statements of the ecclesiastical writers of the first centuries do not agree; according to some it was Parthia, according to others Egypt and Ethiopia, and according to others India, where the Portuguese in the 15th century asserted that they had found his body. An ancient sect of Christians (Christians of St. Thomas), who in the 8th century were numerous in Persia and still survive in India, claim St. Thomas as their founder; but many theologians consider the account of the labors of St. Thomas in India as having been invented by the Manichæans, and as early as the 5th century the Thomas of India was regarded by Theodoret as a disciple of Manes. To the apostle Thomas an *Evangelium Infantia Christi* (also called *Evangelium secundum Thomam*) is ascribed, which pretends to fill up the gaps

eft by the canonical Gospels in the time from the childhood of Jesus until his public appearance; but it has always been regarded as apocryphal. (See Thilo, *Acta Thomæ Apostoli*, Leipsic, 1838.) St. Thomas is commemorated in the Roman Catholic church on Dec. 21; in the Greek church on the first Sunday of her church year, which begins with Easter (hence called Thomas Sunday). He is often represented in pictures with a square and rule or with a measure, because he would not believe unless after examining for himself, or because, according to a legend, he built a palace for the Indian king Gondohar.

THOMAS A KEMPIS. See KEMPIS.

THOMAS AQUINAS. See AQUINAS.

THOMASIVS (THOMAS), CHRISTIAN, a German philosopher and critic, born in Leipsic, Jan. 12, 1665, died in Halle, Sept. 23, 1728. He was educated by his father, the rector of the celebrated *Thomasschule*, and from 1675 to 1679 studied at Frankfort-on-the-Oder. Returning to Leipsic in 1679, he undertook a course of lectures at the university, and in 1687 he began a lecture in the German instead of the Latin language. In 1688 he published his programme in German, and commenced a monthly sheet, which he edited until 1690, under the title of *Freimüthige, lustige und ernsthafte, jedoch vernunft- und gesetzmässige Gedanken, oder Monatsgespräche über allerhand, vornehmlich aber neue Bücher*, which gave him great influence in Germany. The persecution of his enemies finally forced him to flee from Leipsic. He first went to Berlin, where he was kindly received by Frederic III., elector of Brandenburg, afterward King Frederic I. of Prussia. He subsequently began the delivery of lectures at Halle, and his success induced the elector in 1694 to found the university of Halle. In 1709 he received an invitation to become professor of jurisprudence in Leipsic, and in 1710 was made rector of the Halle university, and dean of the faculty of jurisprudence. Thomasius exercised a great influence over his times. It was principally by his exertions that trials for witchcraft and torture were abolished in Germany. He wrote a large number of works, among the most important of which were *Geschichte der Weisheit und Thorheit* (8vo., Halle, 1698), and *Vernünftige und christliche, aber nicht scheinliche Gedanken und Erinnerungen über allerhand, auserlesene, gemischte, philosophische, und juristische Handel* (8 vols., 1723-'6). His life was written by Luden under the title of *Christian Thomasius nach seinen Schicksalen und Schriften* (Berlin, 1805).

THOMASTON, a town and port of Knox co., Me., on St. George river, adjoining the city of Rockland, 15 m. from the coast, and 80 n. E. N. E. from Portland; pop. in 1850, 2,728; in 1860, 3,481. The Maine state prison is situated here, and extensive granite quarries in the neighborhood are worked by convict labor. The inhabitants are chiefly engaged in manufacturing and exporting lime and in ship

building. About 300,000 casks of lime are made annually. The registered shipping of the port is now (1862) about 60,000 tons. There are 2 banks with an aggregate capital of \$100,000, 2 public libraries, 2 insurance offices, an academy, a society of natural history, an iron foundry, a steam mill, and 5 churches.

THOMISTS. See AQUINAS.

THOMPSON, AUGUSTUS CHARLES, D.D., an American clergyman, born in Goshen, Conn., April 30, 1812. He entered Yale college in 1832, but from the failure of his health quitted it before completing his collegiate course. In 1838 he completed his studies at the Congregational theological seminary at East Windsor Hill, Conn., subsequently visited Europe and spent a year at the university of Berlin, and in July, 1842, became pastor of the Eliot Congregational church, Roxbury, Mass., where he still remains. In 1854-'5 he accompanied the Rev. Dr. Anderson as a deputation to the missions of the American board of commissioners for foreign missions in India. He has published the following works: "Songs in the Night" (Boston, 1845; several times reprinted); "The Lambs Fed," which has been translated into the Mahratta language; "The Young Martyrs;" "Last Hours, or Words and Acts of the Dying" (1851); "The Poor Widow, a Memorial of Mrs. Anna F. Waters" (1854; translated into Tamil); "The Better Land, or Believer's Journey and Future Home" (1855); "The Yoke in Youth, a Memorial of H. M. Hill" (1856); "Gathered Lilies, or Little Children in Heaven" (1858); "Feeding the Lambs" (1859); and "Morning Hours in Patmos" (1860).

THOMPSON, BENJAMIN. See RUMFORD.

THOMPSON, DANIEL PIERCE, an American novelist, born in Charlestown, Mass., Oct. 1, 1795. In his childhood his parents emigrated to Berlin, Vt., and he was graduated at Middlebury college in 1820. He afterward taught as private tutor for several years in the vicinity of Alexandria, Va., studying law meanwhile, and was admitted to the bar in Virginia. About 1855 he returned to Vermont and opened a law office in Montpelier, where he still resides (1862), and where he has at different times held the offices of register of probate, clerk of the legislature, compiler of the statutes, judge of probate, clerk of the county and of the supreme court, and secretary of state. His first published work, "May Martin, or the Money Diggers" (1835), gained a prize offered by the "New England Galaxy," and has been many times reprinted in book form. His other works are: "The Green Mountain Boys" (Montpelier, 1840; subsequently republished in Boston); "Locke Amsden," a graphic picture of the New England district school as it was (Boston, 1847); "Lucy Hosmer" (1848); "The Rangers, or the Tory's Daughter" (1850); and "Gant Gurley, or the Trappers of Lake Umbagog" (1857).

THOMPSON, JACOB, an American statesman, born in Caswell co., N. C., May 15, 1810. In

his youth he practised law in Mississippi, which state he represented in the lower house of congress from 1839 to 1851, advocating the repudiation by Mississippi of a portion of the state bonds, and opposing the compromise of 1850 as not conceding enough to the South. On the inauguration of President Buchanan (1857) he became secretary of the interior. In Dec. 1860, while still holding that office, he was appointed by the legislature of Mississippi a commissioner in behalf of that state to urge upon North Carolina the adoption of an ordinance of secession; and on Jan. 7 succeeding, he resigned his secretaryship on the ground that the president, by attempting to send reinforcements to the federal troops in Charleston harbor, had violated a distinct understanding entered into with the cabinet. He participated in the subsequent revolutionary movements of the seceded states, and in Nov. 1861 was elected governor of Mississippi, which he still is (May, 1862).

THOMPSON, JOHN R., an American author, born in Richmond, Va., Oct. 23, 1823. He was educated at the university of Virginia, studied law in the office of James A. Seddon, and subsequently in the law school of the university, and in 1845 was admitted to the bar. In 1847 he assumed the editorship of the "Southern Literary Messenger," published at Richmond, Va., retaining that position for many years, and to that periodical made many contributions. Beside these, he has delivered numerous addresses at colleges, and several lectures, and furnished many articles for literary journals in the North and South.

THOMPSON, JOSEPH PARRISH, D.D., an American clergyman, born in Philadelphia, Aug. 7, 1819. He was graduated at Yale college in 1838, studied theology at Andover and New Haven, and was ordained pastor of the Chapel street Congregational church, New Haven, in Nov. 1840. In April, 1845, he removed to New York, having accepted the charge of the Broadway Tabernacle church, which he still retains (1862). While at New Haven, Mr. Thompson was one of the originators of the "New Englander," a Congregational quarterly review, and has contributed nearly 40 articles to it, many of them on denominational topics. He was also one of the founders of the "Independent" newspaper. In 1852 he originated the plan of the Albany Congregationalist convention, which gave a unity and organic life to that denomination which it had not previously possessed. He is also a manager of the American Congregational union, and of the American home missionary society. In 1852 he sailed for Europe and the East, and was absent about two years, exploring Palestine, Mt. Sinai, Egypt, and other oriental countries; and he has since devoted much time to oriental studies, especially Egyptology, the results of which have appeared in his contributions to the "North American Review," the "Bibliotheca Sacra," the "Journal of the American Geographical and Statistical

Society," Smith's "Dictionary of Biblical Geography and Antiquities," and the revised edition of Kitto's "Cyclopædia of Biblical Literature." Harvard university conferred upon him the degree of D.D. in 1856. Beside numerous sermons, addresses, and occasional pamphlets, Dr. Thompson has published: "Memoir of Timothy Dwight" (New Haven, 1844); "Lectures to Young Men" (New York, 1846); "Hints to Employers" (1847); "Memoir of David Hale" (1850); "Foster on Missions, with a Preliminary Essay" (1850); "Stray Meditations" (1853; revised ed. entitled "The Believer's Refuge," 1857); "The Invaluable Possession" (1856); "Egypt, Past and Present" (Boston, 1856); "The Early Witnesses" (1857); "Memoir of Rev. David T. Stoddard" (New York, 1858); "The Christian Graces" (1859); and "Love and Penalty" (1860).

THOMPSON, ROBERT ANCHOR, an English clergyman and author, born in Durham in 1821. He was educated at Cambridge, and, after being attached for some time to the observatory of Durham, entered holy orders, was appointed curate of Louth, and in 1854 of Binbrooke, Lincolnshire, and is now master of the hospital of St. Mary the Virgin at Newcastle-upon-Tyne. In 1849 he published some astronomical observations at the expense of the university of Durham; in 1853 a volume of sermons; in 1855 "Christian Theism," which took the Burnett prize of £1,800; and in 1857 "Principles of Natural Theology."

THOMPSON, THOMAS PERRORET, an English author and political reformer, born in Hull in 1783. In 1803 he entered the navy as midshipman, and in 1806 went into the army as second lieutenant. In 1808, through the influence of Wilberforce, he was made governor of Sierra Leone. One of his first acts was to issue a proclamation for the suppression of the slave trade in the colony; and the opposition raised against him by the slave traders caused his recall by Lord Castlereagh, and arriving in England in 1810 he returned to the army, served in the peninsular campaigns of 1813 and 1814, and afterward in the Pindaree campaign in India. In 1819, having learned Arabic, he accompanied Sir William Keir Grant in the expedition up the Persian gulf, and assisted in the negotiation of the treaty with the Arab tribes, by which the slave trade was declared piracy. In 1854 he was made major-general. In 1814 he wrote a work entitled "On a Constitution." He was one of the contributors to the "Westminster Review" on its establishment in 1824, and 5 years afterward became joint proprietor, writing for it constantly until 1836, and treating among other things of free trade, slavery, Catholic and Jewish disabilities, property tax, and other reform questions of the day; his "Corn Law Catechism," which appeared in 1827, was the most effective attack which the protectionist system of commercial policy received. In 1835 he was elected to the house of commons from Hull, was not returned in the

general election of 1837, but sat afterward for Bradford in Yorkshire, and was elected again in 1857. A selection from his miscellaneous writings was published in 1842 in 6 volumes.

THOMPSON, WADDY, an American lawyer and statesman, born at Pickensville, Pendleton district, S. C., Sept. 8, 1798. He was graduated at the South Carolina college, studied law, was admitted to the bar in Dec. 1819, and rapidly rose to the head of his profession. In 1826 he was elected to the state legislature, where he continued to serve till his election by the legislature in 1830 as solicitor of the western circuit. When the militia of the state was reorganized, on the nullification excitement, he was elected by the legislature brigadier-general. In 1835 he was elected a representative in congress, and served 3 terms, taking an active part as a whig in all the great debates of that body. When Mr. Calhoun, who lived in his district, went over to the democratic party, all the whig members from the state did the same except Mr. Thompson. This opposition to Mr. Calhoun led to a most exciting canvass at the ensuing election in South Carolina, in which Mr. Calhoun took the stump against Gen. Thompson, who however was reelected by more than 1,000 majority. As soon as the election was over, Gen. Thompson announced his determination to retire from public life and devote himself to his professional and private pursuits. In 1842 he was appointed minister to Mexico by President Tyler. During the period of his mission, he made two important treaties, and procured the liberation of more than 200 Texan prisoners, many of whom were sent home at his own charge. On his return home he wrote a work entitled "Reminiscences of Mexico," which passed through several editions. Gen. Thompson is an extensive and successful cotton planter in Florida, but resides at his home, near Greenville, S. C.

THOMPSON, WILLIAM, a British naturalist, born in Belfast, Nov. 2, 1805, died in London in Jan. 1852. He was educated for a commercial life, in 1821 was apprenticed to a linen merchant of Belfast, and in 1832 gave up business and began the study of animals and plants, but especially of birds. To the "Proceedings of the Zoological Society" of London he contributed numerous papers on the natural history of Ireland. In 1840 he prepared for the British association for the advancement of science a "Report on the Fauna of Ireland, Division Vertebrata." In 1841 he accompanied Professor Forbes on a tour to the Grecian archipelago; from 1841 to 1843 contributed frequently to the "Annals of Natural History;" and in 1843 read to the British association, which met at Cork, a further report on the invertebrate fauna of Ireland. Of his great work on the "Natural History of Ireland," the first 3 volumes, devoted to birds, appeared in 1849-'51; but he died before finishing it. In 1856 the 4th volume was published, with a biography of the author, edited by Prof. Dickie.

THOMPSON, ZADOC, an American naturalist, born in Bridgewater, Vt., in 1796, died in Burlington, Vt., Jan. 19, 1856. He was graduated at the university of Vermont in 1823, and in 1824 published the first edition of his "Gazetteer of Vermont." For several years subsequently he was engaged in teaching, and in 1836 he was ordained deacon in the Protestant Episcopal church, but preached only occasionally. In 1842 he published the "Natural, Civil, and Political History of Vermont, and of its various Institutions," followed by a greatly enlarged edition of his "Gazetteer." He was soon afterward appointed professor of natural history and chemistry in the university of Vermont, which office he filled till 1853. He accumulated at Burlington a very complete cabinet of the natural history of the state, which at his death passed into the possession of the university. In 1851 he visited Great Britain as a commissioner from Vermont to the exhibition of the industry of all nations; and a collection of American woods, classified according to their useful properties, which he exhibited, attracted much attention and received the great bronze medal of the exhibition. In 1853 Prof. Thompson was appointed state naturalist, and directed to make a survey of the state, including its physical geography, geology, mineralogy, botany, and general zoology, upon which he was engaged at the time of his death. Beside the works mentioned, he published several school books and small treatises, and in 1853 an appendix to his "Natural History of Vermont."

THOMS, WILLIAM JOHN, an English antiquary, born in Westminster, Nov. 16, 1808. He was originally placed in the secretary's office at Chelsea hospital, was for some years clerk of printed papers in the house of lords, and in 1862 was appointed sub-librarian of that house. He wrote for various periodicals, but his first separate publication was "A Collection of early Prose Romances" (8 vols., 1828). This was followed by "Lays and Legends of Various Nations" (1834) and "Book of the Court" (1838); he was also editor of "Anecdotes and Traditions" (1839) and "Caxton's Reynard the Fox" (1844). His reputation rests principally on the establishment of the "Notes and Queries," in the editing of which he has been assisted by a large circle of friends.

THOMSON, ANTHONY TOWN, a British physician, born in Edinburgh, Jan. 7, 1778, died at Ealing, Middlesex, July 8, 1849. He was educated at the high school of Edinburgh, studied medicine, attending the lectures of Munro, Black, Gregory, and Dugald Stewart, in 1798 became a member of the speculative society and was intimately associated with Jeffrey, Brougham, Horner, Lord Cockburn, and Lord Lansdowne, in 1799 became a member of the royal medical society, and in 1800 settled in London as a general practitioner. His contributions to medical and botanical science were very extensive and valuable. In 1826 he became a member of the royal college of phy-

sicians, and in 1828 professor of materia medica in London university, now University college. In 1832 he was appointed professor of medical jurisprudence, which position he held till his death. His works were extensive and valuable. Of "The London Dispensatory" (8vo., 1811), 10 editions were published during his life, and it was translated into several of the European languages; his "Elements of Materia Medica" (8vo., 1832) was frequently republished in England and America.—Mrs. A. T. Thomson, wife of the preceding, has published "Memoirs of the Court of Henry VIII." (2 vols. 8vo., London, 1826); "Memoirs of Sarah, Duchess of Marlborough, and of the Court of Queen Anne" (2 vols. 8vo., 1839); "Memoirs of the Jacobites of 1715 and 1745" (8 vols. 8vo., 1845); "Memoirs of the Viscountess Sundon," &c. (2 vols. 8vo., 1847); "Recollections of Literary Characters and Celebrated Places" (2 vols. 8vo., 1858); and 9 or 10 novels.

THOMSON, CHARLES, an American patriot, born in Ireland in Nov. 1729, died in Lower Merion, near Philadelphia, in 1824. He came to America at the age of 11, was educated in Maryland, taught a Friends' academy in Philadelphia, and afterward went into business in that city. From the beginning he was ardently devoted to the cause of the colonies, and in 1774, upon the assembling of the continental congress, was elected its secretary. John Adams speaks of him in his "Diary" at that time as "the Sam. Adams of Philadelphia, the life of the cause of liberty." He remained secretary until the close of the war, and was chosen to inform Washington of his nomination to the presidency. He afterward retired entirely from public life, and occupied his later years in a translation of the Septuagint, which was published in 4 vols. in 1808.

THOMSON, EDWARD, D.D., an American clergyman, born at Portsea, England, in 1810. He came to America in 1819, attended medical lectures in Philadelphia and Cincinnati, and entered upon the practice of his profession in 1829. In 1832 he entered the ministry of the Methodist Episcopal church, and was stationed successively at Norwalk, Sandusky, Cincinnati, Wooster, and Detroit. In 1838 he was chosen president of the Norwalk seminary, which post he occupied for 5 years, when he was elected professor of mental and moral philosophy in the university of Michigan, and edited the "Ladies' Repository" until called to the position of president of the Ohio Wesleyan university. At the general conference in 1860 he was elected editor of the "Christian Advocate and Journal," New York.

THOMSON, JAMES, a British poet, born in Ednam, Roxburghshire, Scotland, Sept. 11, 1700, died at Kew Lane, near Richmond, Aug. 27, 1748. He was the son of a clergyman, and being destined for the church was sent in his 18th year to the university of Edinburgh, where he passed 6 years, the last 4 of which

were devoted to theological studies. In 1724 he left Edinburgh to push his fortunes in London, and for several months discharged the duties of tutor in the family of Lord Binning. Previous to this time he had given indications of poetic talent, and a fragment of blank verse, written at the age of 14 and first published in a life of the poet by Allan Cunningham in 1841, possesses considerable merit as a boyish effusion. He now set about the composition of a more elaborate work, and, encouraged by his college friend Mallet, published in March, 1726, his blank verse poem of "Winter," for the copyright of which he received 3 guineas. It attracted so much attention that a 2d and a 3d edition were called for in the same year. In 1727 appeared "Summer," followed by "Britannia" and a "Poem sacred to the Memory of Sir Isaac Newton;" in 1728 "Spring;" and in 1730 he published "The Seasons," completed by the addition of "Autumn," in a 4to. volume, of which 454 copies were subscribed for at a guinea each. Pope, to whom the author had been introduced by Mallet, took 3 copies. In 1729 he also produced "Sophonisba," a tragedy, acted with moderate success at Drury Lane. In 1731 he visited the continent as travelling tutor of the son of Sir Charles Talbot, afterward lord chancellor, and upon his return to England in the succeeding year commenced an elaborate poem in 5 parts upon "Liberty," which appeared in 1735-'6. He regarded it as the best of his productions, but, as Dr. Johnson has observed, "Liberty called in vain upon her votaries to read her praises and reward her encomiast; none of Thomson's performances were so little regarded." It was abridged by Lord Lyttelton in collecting the author's works for publication, and in that condition it still appears. He had meanwhile been placed in easy circumstances by the appointment of secretary of briefs in the court of chancery, bestowed upon him by Lord Talbot; but upon the death of the chancellor in 1737, his successor, Lord Hardwicke, after waiting for some time for Thomson to make a formal application for the place, bestowed it upon another. He was however soon after introduced to the prince of Wales, then emulous of the reputation of a patron of literature, and received from him a pension of £100 a year. He now resumed his dramatic labors, and produced his "Agamemnon" (1738), which, in spite of the presence of Pope and the acting of Quin, both warm friends of the poet, narrowly escaped being damned on the first night of the performance. It was followed by "Edward and Eleanora," the representation of which on the stage was prohibited under the operation of the act for licensing dramatic performances; by the masque of "Alfred," written in conjunction with Mallet, and which contains the celebrated song and chorus, "Rule Britannia," set to music by Dr. Arne; and by "Tancred and Sigismunda," performed with

success at Drury Lane in 1745. About this time he was raised to comparative opulence by his appointment, through the influence of Lyttelton, to the office of surveyor-general of the Leeward islands, the duties of which were discharged by a deputy, while the clear emoluments amounted to £800 a year; and the latter part of his life was passed in ease and tranquillity at an elegant retreat at Kew Lane. In 1748 appeared the "Castle of Indolence," a poem in the Spenserian stanza, on which he had labored for many years, and which is esteemed the most finished and poetical of his larger works. He died soon after of a fever resulting from exposure in the night air. His posthumous play of "Coriolanus" was subsequently performed at Covent Garden, and the profits, after the discharge of his debts, were emitted to his sisters.—Thomson was a man of gross appearance and exceedingly indolent disposition, and was unwavering in his attachment to his friends. Lord Lyttelton has pronounced the best eulogy upon him in his prologue to "Coriolanus," in which it is said that his works contained "no line which, dying, he could wish to blot." The "Seasons" have preserved their popularity to the present time, and are frequently republished.

THOMSON, THOMAS, a British chemist, born at Crieff, Perthshire, April 12, 1773, died July 1, 1852. He was educated at the university of St. Andrew's and at Edinburgh, and in 1796 became connected with the "Encyclopædia Britannica," and the chemical articles furnished by him to that work were the basis of his "System of Chemistry" (4 vols. 8vo., 1802). He began to lecture on chemistry at Edinburgh in 1800, was the first to suggest the use of chemical symbols, and was one of the first to elucidate the atomic theory of Dalton. In 1810 he published the "Elements of Chemistry" (8vo.); in 1812, the "History of the Royal Society of London" (4to.); and in 1813, "Travels in Sweden," which country he had visited in the previous year. In 1818 he went to London and commenced the "Annals of Philosophy," which he continued to edit until 1823. In 1817 he was chosen lecturer at the university of Glasgow, and in 1818 was made professor of chemistry, which position he held until his death. In 1825 he published "An Attempt to Establish the First Principles of Chemistry by Experiment" (2 vols.), which was followed by "The History of Chemistry" (3 vols., 1830-'31), "Outlines of Mineralogy and Geology" (2 vols., 1836), and "Brewing and Distillation" (1849).—His son, of the same name, is a distinguished botanist, now superintendent of the East India Company's botanic gardens at Calcutta, and has published an account of his travels in Thibet.

THOR, in Scandinavian mythology, the first-born of Odin and Frigga, the bravest and boldest of all the gods. He directed the winds and the seasons, and was the Jupiter of the Scandinavians. In the Eddas he appears as the champion of gods and men, destroying monsters and

giants with his bolts of thunder. A terrible club or hammer was hurled at his victim, and the blow having been dealt, the weapon returned to his hand. His waist was bound with a girdle which for ever renewed the strength he spent in battle. Thursday is named for him.

THORAX, the anatomical name of the bony framework formed by the breast bone, ribs, and spine, which contains and protects the lungs, heart, and great vessels, and including a cavity separated from the abdomen by the diaphragm; the cavity is lined by serous membrane, and its movements are the chief agents in the process of respiration; a thorax as thus defined exists in its perfect form only in mammalia. The movements of the thorax (see RESPIRATION) are rendered more easy and extensive by the cartilages which connect the ribs in front with the sternum. The bony thorax protects not only the lungs and heart, but extends down so as to cover the liver, spleen, kidneys, stomach, duodenum, and part of the colon. Covered with the muscles and with the upper extremities attached, it forms a cone with the apex downward; in the skeleton the apex is upward; the back and shoulders may be very broad without indicating a wide and capacious thorax, the diameter of the lower part of the neck corresponding better with that of the apex of the thorax; Freeman, the American giant, measured 26 inches from tip to tip of the shoulders, but only 6 inches across the lower part of his neck. The human thorax is flattened antero-posteriorly, while that of the lower mammals is flattened from side to side. In the fœtus the thoracic is much smaller than the abdominal cavity, from the inactivity of the lungs; at birth it suddenly enlarges, increases perceptibly to puberty, and even grows larger in adult age to its full development; as age advances it tends to collapse and the bony framework to become a rigid cage from ossification of the costal cartilages, the apex comes forward, and the round back of the old man appears. The thorax may be distorted by curvature of the spine from disease, occupation, improper attitudes, and neglect of physical education, especially in female youth; it may also be deformed by pleurisy, emphysema, phthisis, and various articles of dress, particularly corsets; these last act chiefly on the 5th to the 10th ribs, pressing them forward and inward, their longer cartilages allowing them to yield readily, carrying with them out of place the organs of the chest and abdomen. At the Hôtel Dieu at Paris a girl of 18 lately presented herself to M. Breschet, with a soft, elastic tumor in the neck, extending from the collar bone to Adam's apple (thyroid cartilage), which proved to be a portion of the lungs forced out of the chest into the neck by the compression of corsets. The old-fashioned busk of steel, whalebone, or wood caused much deformity of the chest, by inward depression of the breast bone. Instead of 8 or 9 inches, the antero-posterior diameter of the thorax in a tightly laced woman

is not unfrequently reduced to 3 or 2. The so called pigeon or chicken breast, in which the ribs are drawn in and the breast bone protruded, is frequently if not generally caused by obstruction to respiration from enlarged tonsils or other disease in the air passages. The thoracic cavity corresponds with the volume of the heart and lungs, but there is no necessary relation between the volume of the latter and the vigor of the constitution, nor between the size of the cavity and the amount of respired air or the volume of the abdominal cavity; it is generally true, however, that a large abdominal cavity is found with a small thorax. Taking the most perfectly formed male chests, both from living persons and the classic statues of ancient athletes, it is found that, between the heights of 5 and 6 feet, for every inch of stature there is an increase of $\frac{1}{4}$ to $\frac{1}{5}$ of an inch in the circumference of the thorax, whether the weight be taken at the minimum, average, or maximum at the respective heights; the circumference varies from 30 to 37 inches at 5 feet, and from 35 $\frac{1}{2}$ to 44 $\frac{1}{2}$ at 6 feet. The internal diameter bears no relation to the height or weight of the individual, but the vital capacity or the measure of the mobility of the thorax does in a very exact ratio.

THORBECKE, JOHANNES RUDOLPH, a Dutch statesman and publicist, born in Zwolle in 1796. He studied at the university of Leyden and various German universities, and in 1825 was made professor of political sciences in the university of Ghent, and in 1830 in that of Leyden. In 1840 he was elected to the legislative body, and in 1844, with 7 other delegates, proposed to the king a revision of the constitution, which the latter rejected as too liberal; but in March, 1848, he was placed at the head of a commission for revising the constitution, which adopted the plan proposed in 1844. In Oct. 1849, he was called to form a ministry composed of members of the constitutional progressive party, in which he took charge of the department of the interior and effected several important reforms. In April, 1853, he was compelled to resign, and resumed his functions in the university of Leyden; but at the commencement of 1862 he again became prime minister. He is the author of several legal and political works.

THOREAU, HENRY DAVID, an American author, born in Boston, Mass., July 12, 1817, died in Concord, May 6, 1862. He was graduated at Harvard college in 1837, and was subsequently engaged in teaching school and in trade, and was also a contributor to the "Dial." In 1849 he published "A Week on the Concord and Merrimack Rivers," and in 1854 "Walden, or Life in the Woods," in which he describes a hermit life of more than two years in a forest near Concord, beginning in March, 1845.

THORILD, THOMAS, a Swedish author, born in Kongelf, in the län of Gothenburg, in 1759, died in Greifswalde, Oct. 31, 1819. While a tutor at the university of Upsal, he submitted

to the states of the realm a plan for an act for the freedom of the press, but was not permitted to print it; and in consequence of an attempt to have it published, he was banished for 4 years. He went first to Copenhagen, where he published a treatise "On the Natural Greatness of the Female Sex;" in 1795 he went to Altona, and subsequently became librarian and professor of the Swedish language and literature in the university of Greifswalde. As a metaphysician he is known by his work entitled *Maximum, sive Archimetria* (Berlin, 1799). There is a collection of his poems and other writings edited by Geijer (8 vols., Upsal, 1819-'25).

THORKELIN, GRAM JONSSON, an Icelandic scholar, born in Iceland in 1752, died in Copenhagen in 1829. His reputation was first established by his editions of the Icelandic ecclesiastical laws entitled *Jus Ecclesiasticum Vetus seu Thorlaco-Katillianum*, and *Jus Ecclesiasticum Novum Arnæum*. In 1786 he undertook an antiquarian journey through England, Ireland, and Scotland, and published "Fragments of English and Irish History in the 9th and 10th Centuries" (London, 1788), and *Mores de Africa Commentarius* (London, 1789). His great work was his collection for Danish-Norwegian history entitled *Diplomatarium Arno-Magnæum* (2 vols., Copenhagen, 1786). Beside these, he superintended an edition of the *Byrbyggja-Saga* (1787), of the Anglo-Saxon poem of Beowulf with a Latin translation (1815), and of the law book of Magnus Lagabæster entitled *Gula-things Laug* (1817).

THORLACIUS, SKULÉ THORSSON, a northern antiquary, born in Iceland in 1741, died in Copenhagen in 1815. He was one of the first cultivators of the old northern literature, and at the time of his death was rector of the Latin school. He had a principal part in the editing of the third volume of the *Heimskringla* of Snorro Sturleson (Copenhagen, 1783), and wrote various important essays on northern antiquities.—BÖRG, son of the preceding, born in Colburg, May 1, 1775, died in Copenhagen, Oct. 8, 1829, was at the time of his death professor of eloquence in the Copenhagen university. He followed in his father's footsteps in the investigation of the northern language and literature, furnished the means for the publication of the second part of the *Sæmundis Edda*, and wrote various works on cognate subjects.

THORLAKSSON, JON, an Icelandic poet, born in Selardal, near Arnarfjord, Dec. 13, 1744, died in Bægisla, Oct. 21, 1819. He was educated for the priesthood, but in 1772 was dismissed from it for an alleged crime, and was not restored until 1780, having in the mean time supported himself as corrector of the press. About 1788 he was presented with the living of Bægisla in the north of Iceland, the value of which was nearly \$35 a year, but was reduced by the necessity of employing a curate. Here he made a version into Icelandic of "Paradise Lost" from the Danish, the first 8 books of which were published by the Icelandic literary

society; but that association failing for want of funds, the work was left in manuscript, and was not printed until 1828 at Copenhagen. Thorklaksson wrote numerous other poems, but his fame rests on this version. Shortly before his death he received a pension of \$80 a year from the king of Denmark. His collected poems fill about 1,100 pages in the *Islenak Ljóðabók Jóns Thorklakssonar Prests ad Bagia* (2 vols., Copenhagen, 1842-'8).

THORN (*crataegus*, Linn.), the common name of spiny shrubs or bushes, having conspicuous foliage, showy flowers, and beautiful fruits. Several different species are to be found throughout all the northern portions of the globe. The most common thorn of Europe and of England is the sharp-thorned hawthorn (*C. oxyantha*, Linn.), which has deeply lobed and somewhat shining leaves, small, fragrant flowers, and small, shining haws or fruits, and is esteemed among the best hedge plants of Great Britain. There are several distinct varieties, much prized as ornamental shrubs. When planted in rich soils they attain a considerable height, and are handsome and graceful, especially if spared the pruning knife. The double white, the scarlet-flowered, and the double scarlet-flowered are indeed exquisitely beautiful, tree-like plants. Loudon gives 40 varieties, all of which are remarkable, and cultivated by amateurs. The Glastonbury horn (*C. o. præcox*) leaves out as early as January or February, and has been known to flower at Christmas, giving rise to a legend of its having sprung from the staff of Joseph of Arimathea. The common or sharp-thorned hawthorn of Europe was well known to the Greeks of ancient times as the *pyracantha*, although it is doubtful whether they or the Romans employed it in any useful way. It has fallen into disrepute in the United States as a hedge plant, being liable to the attack of insects, and in midsummer despoiled of the beauty of its foliage by the red spider.—What are termed oriental thorns are very similar in having deeply cut leaves, but so covered with hairs as to cause them to assume a dull gray or hoary aspect; their flowers however are large and fragrant, and their fruits likewise large and succulent. In expression and shape they are described by writers as less elegant than the hawthorns, being formal and rounded; but the fragrance of blossom and the size and beauty of fruit compensate in a great degree. The sweet-scented (*C. odoratissima*, Bot. Reg.) with its red, the tansy-leaved (*C. tanacetifolia*) with its yellow, the eastern (*C. orientalis*) with its purple, and the *C. aronia* with its light orange-colored fruits, are all highly recommended. To this group of thorns belongs the azarole, with globose, scarlet haws, found wild in small woods and rough places in the south of France and in Italy. Its flowers are borne in corymbs toward the extremities of the branches; they are middle-sized, and are succeeded by round, somewhat oval fruits,

which vary exceedingly in dimensions in different plants raised from seed; they are most generally of a yellowish red color. The ripened haws are mealy and somewhat acid; and in Italy and the Levant they are sometimes used as table fruits. Six distinct and permanent varieties are known in France: the hairy-leaved, the white Italian azarole, the double-flowered, the long whitish-yellow fruited, the yellowish-white fruited, and the deep-red fruited.—The American thorns have less deeply cut leaves and smaller fruits than these last, and sharp spines or thorns. The cockspur thorn (*C. crus-galli*, Linn.) has deep green shining leaves and very strong and long spines, and this with its varieties has been usefully employed for hedges. The Washington thorn (*C. cordata*, Aiton) has a stem from 15 to 20 feet high, furnished with numerous, slender, dark purple branches armed with sharp slender spines, which are about 2 inches in length; it is a native of Virginia, according to Darlington, and has been recommended for making hedges. The white thorn or scarlet-fruited thorn (*C. coccinea*) has a stem of about 12 feet in height, and rugged spreading branches, which are armed with short spines, the color of the fruit giving to it the specific name. This species grows in some situations to the stature of small trees, and affords food for numerous kinds of birds. The black or pear thorn (*C. tomentosa*, Linn.) has several varieties, supposed by some to be distinct species; it is a tall shrub or low tree, usually with large, globular or pear-shaped, crimson or orange red, eatable berries or haws. According to Torrey and Gray, the number of American species is 17, of which several are to be found in the extreme southern states. There is scarcely any other hardy shrub affording so much interest to ornamental planting, or which would attract so many kinds of valuable and useful birds.

THORN APPLE. See DATURA.

THORNBAC. See RAY.

THORNHILL, SIR JAMES, an English painter, born in Weymouth in 1676, died in the vicinity of that town, May 4, 1734. He was descended from an ancient family of Derbyshire, and was compelled by the extravagance of his father to take up painting as a profession. Having settled in London, where he received liberal assistance from his maternal uncle, the celebrated Dr. Sydenham, he soon rose into considerable reputation, and during the last 80 years of his life was employed on the most important works of art undertaken in Great Britain. Among these were the 8 pictures in chiaroscuro illustrating the history of St. Paul on the inner dome of St. Paul's cathedral, London, and the decorations at Kensington palace, Blenheim, and Greenwich hospital, none of which have much to recommend them beside their vastness, although the composition is not inferior to that of contemporary works of the class. He also executed two sets of copies of the cartoons of Raphael at Hampton Court, one

of which is now in the possession of the royal academy. In 1724 he opened an academy for drawing at his house in Covent Garden, where Hogarth, who afterward effected a stolen union with his daughter, received his first and only regular instructions in art. Thornhill was knighted by George I.

THORNTON, BONNELL, an English author, born in London in 1724, died May 9, 1768. He was educated at Oxford, and began the study of medicine, but quitted it for literature, and in conjunction with George Colman the elder began a series of periodical essays, called "The Connoisseur," which lasted from Jan. 4, 1754, to Sept. 30, 1756. With Colman also he was one of the original proprietors of "The St. James's Chronicle." In 1762 he published "An Ode on St. Cecilia's Day, adapted to the antient British Music, viz., the Salt-box, the Jews-harp, the Marrow-bones and Cleavers, the Hum-strum or Hurdy-gurdy, &c., with an Introduction giving an Account of those truly British Instruments" (4to., London); the ode was set to music by Dr. Burney, and performed on the instruments named with great success. In conjunction with Colman and Richard Warner he published "The Comedies of Plautus, translated into familiar Blank Verse" (3 vols., 1767), of which he translated "Amphitryon," "The Braggart Captain," "The Treasure," "The Miser," and "The Shipwreck." In 1768 he published "The Battle of the Wigs, an additional Canto to Dr. Garth's Poem of the Dispensary" (4to.).

THORNWELL, JAMES HENRY, D.D., an American clergyman, born in Marlborough district, S. C., in 1811. He was graduated at the South Carolina college in 1829, and soon after commenced the study of law, which he abandoned for theology, and commenced preaching as a Presbyterian minister to the Waxhaw church. In 1836 he was elected professor of logic and belles-lettres in the South Carolina college, but after two years resigned to become pastor of the Presbyterian church in Columbia, S. C. In 1840 he accepted the professorship of the evidences of Christianity and the chaplaincy of the college, which he held till May, 1852, when he took charge of the Glebe street church, Charleston. In December of the same year he was elected president of the college, and in 1856 resigned to take a professorship in the Presbyterian theological seminary at Columbia, where he still remains. Dr. Thornwell has published, beside numerous sermons and occasional pamphlets, essays, addresses, &c., "Arguments of Romanists Discussed and Refuted" (New York, 1845), and "Discourses on Truth" (New York, 1854). In the secession movement of 1860-'61 he wrote with zeal and ability in advocacy of the southern policy.

THOROUGH BASE, the art by which harmony is superadded to any proposed base. The term is also used like counterpoint as synonymous with the science of harmony. (See Music, and HARMONY.)

THOROUGHWORT. See BONESSET.

THORPE, BENJAMIN, an English philologist, born about 1808. He devoted himself to the study of Anglo-Saxon, and translated the Anglo-Saxon grammar of Rask in opposition to Kemble, who followed the system of Grimm. He superintended a series of good editions of Anglo-Saxon works, of which the first was the metrical paraphrase of the Bible by Ceadmon, with a translation and notes, which appeared in 1832. He has published *Analecta Anglo-Saxonica* (1834), a selection of extracts from Anglo-Saxon literature with a vocabulary attached; "The Anglo-Saxon Version of the Story of Apollonius" (1834); *Libri Psalmorum Versio Antiqua Latina, cum Paraphrasi Anglo-Saxonica* (1835); the great collection entitled "Ancient Laws and Institutes of England, with a Compendious Glossary," &c. (1840); *Codes Eboracensis* (1842); "Northern Mythology" (3 vols., 1853), a critical collection of the legends of Scandinavia and northern Germany; and "The Anglo-Saxon Chronicle" (3 vols. 8vo., 1861). He receives from government a pension of £150.

THORPE, THOMAS BANGS, an American author and artist, born in Westfield, Mass., March 1, 1815. He is the son of a clergyman, and passed his earlier years chiefly in the city of New York. At the age of 16 he painted a picture illustrative of Irving's "Bold Dragoon," which was exhibited at the American academy of fine arts, and was purchased by a member of the Irving family. After spending 3 years at the Wesleyan university, Middletown, Conn., he settled in 1836 in Louisiana, where he became connected with the press, but still found time to paint a few pictures, among which is a full-length portrait of Gen. Zachary Taylor, now in the representatives' hall of the capitol of Louisiana. Under the title of "Tom Owen the Bee-Hunter," he published a series of sketches of western and southern life, among the most prominent of which is his "Big Bar of Arkansas." During the Mexican war he was a bearer of despatches to Gen. Taylor, under whom he saw much of military life; and after the fall of Matamoras he published a volume entitled "Our Army on the Rio Grande" (12mo., Philadelphia, 1847), which was followed by "Our Army at Monterey" (12mo., 1848). He returned to New York in 1853, where he published a new collection of his sketches entitled "The Hive of the Bee-Hunter," and became a frequent contributor to "Harper's New Monthly Magazine." In 1860 he exhibited his large picture of "Niagara as It Is," in which for the first time the three falls were represented at one view on canvas; and he now (1863) divides his time equally between the pen and pencil.

THORWALDSEN, ALBERT BERTTEL, a Danish sculptor, born near Copenhagen, Nov. 19, 1770, died there, March 25, 1844. He was the son of Gottskalk Thorwaldsen, a native of Iceland, and by profession a carver in wood, and at the age of 11 was admitted as a pupil in the free school of the academy of arts in Copenhagen. In a year or two he was enabled to

improve upon his father's carvings; at 17 he gained the silver medal of the academy; at 20 the small gold medal for a composition representing Heliogorus driven from the temple; and in 1798 the grand prize, which secured him a royal pension for a term of years, to enable him to study abroad. Various circumstances prevented his departure from Denmark until 1798, and for several years subsequent to his arrival in Rome, where he had determined to pursue his studies, his progress, owing in part to the troubled character of the times, in part to his own diffidence and distrust of his powers, received no adequate recognition. Depressed by his ill fortune, he was preparing in 1803 to return to Denmark, when his model of Jason bearing the golden fleece attracted the notice of Thomas Hope, who immediately offered him a liberal sum to complete the work in marble. From this time commissions poured rapidly in upon him, and in a few years he rose to the head of his profession in Europe, Canova being the only sculptor who disputed his preëminence. His earliest efforts reflected the severe idealism of the classic marbles which had been the chief objects of his study and admiration in Rome, and his *Mars*, *Mercury*, *Ganymede*, the *Graces*, *Venus*, *Cupid* and *Psyche*, *Hector* and *Priam*, the "Dance of the Muses on Mount Helicon," and other subjects of the pseudo-classical school, are among the most successful modern imitations of the antique. A larger and more important work than any of these was the magnificent bass-relief, 60 feet in length, representing the "Triumphal Entry of Alexander into Babylon," the plaster cast of which was completed in 1812 at the command of Napoleon, as a decoration for one of the large apartments of the Quirinal palace. Two copies in marble are in existence, one of which is now in the palace of Christiansborg, Copenhagen. As Thorwaldsen gained in confidence and executive power, however, he rose above the mere imitation of Greek sculpture, and found in works of an earnest, religious character and contemporary interest the true sphere for the exercise of his genius. In 1819 he yielded to the entreaties of his countrymen, who had endeavored in vain to prevail upon him to settle among them, and made a brief visit to Copenhagen. His progress thither through Italy and Germany was one continuous ovation, and upon arriving at his native city he was received with acclamations by a vast multitude, who escorted him in triumph to the apartments prepared for him in the royal palace of Charlottenborg. Returning to Rome in 1820, he commenced the great series of religious works which stamp him as one of the regenerators of sculpture. Preëminent among these was his celebrated colossal group of "Christ and the Twelve Apostles," which now stands in the cathedral church of Copenhagen. The figure of Christ may challenge comparison with any statue of ancient or contemporaneous art for dignity, simplicity, and deep feeling, and the

whole work is justly considered the sculptor's masterpiece. In the same church are his statues of the four great prophets and a number of exquisite bass-reliefs, and the exterior is adorned by his frieze of "Christ bearing the Cross," and by a numerous group in alto-relievo representing the "Preaching of St. John," which fills the pediment. He also executed equestrian statues of Maximilian Frederic of Bavaria and Prince Poniatowski, a fine seated statue of Galileo, one of Copernicus in Warsaw, and one of Byron, now in Cambridge; a monument to Pius VII., numerous illustrations in bass-relief of abstract qualities and passages in sacred history, and a vast number of busts and miscellaneous works. His largest single work is the colossal lion near Lucerne in Switzerland, which commemorates the fidelity of the Swiss guards who fell in defending the Tuileries, Aug. 10, 1792; and among his statues in bronze are those of Schiller at Stuttgart and of Gutenberg at Mentz. In 1838 he returned to Denmark in a frigate placed by the government at his disposal, and was again received by the entire population of Copenhagen, from the king downward, with an affectionate ovation, and lodged in the royal palace. He made a brief visit to Rome in 1841 for the benefit of his health, and died suddenly, two years after his return to Copenhagen, of disease of the heart, just after he had taken his seat at the theatre. His remains, after lying in state for several days at the academy, were interred with extraordinary honors in the presence of an immense concourse of people. He was engaged until within a few hours of his death upon a statue of Luther, which was left unfinished. He was a man of much modesty, generosity, and amiability, and in his old age presented a truly patriarchal appearance with his white locks falling in masses over his shoulders. "His face," says his countryman Holberg, "had the plastic characteristics of one of his own admirable statues; when he moved in the midst of a crowd, it would separate as if it felt the presence of a superior being." Thorwaldsen has often been compared with his great contemporary Canova, whom he excelled in force of expression, in largeness of style, and in the power of his imagination, if inferior to him in the refinements of execution, and in the softness and beauty of his female forms; the difference of aim between the two being as marked as that which distinguished the sculptors of the Phidian era and of that in which Praxiteles flourished. As a sculptor of bass-relief the Danish artist surpassed any of his contemporaries; and some of his smaller works in this department, as the "Day" and "Night," now in the possession of the duke of Devonshire, and which were modelled in 1815 at a single sitting, display a fertile vein of poetic imagination and executive refinement. In other works of the class he neglected the execution for the purpose of attaining vigor and strength of character. His entire collection of works of art, and the bulk

of his large personal property, were bequeathed to the city of Copenhagen for the purpose of establishing and supporting the celebrated museum which bears his name, and which is one of the most famous depositories of art treasures in Europe. It contains copies in marble or plaster of all his works, and is destined to receive those left by him in an unfinished state, and toward the completion of which the Danish government contributes an annual appropriation.

THOU, JACQUES AUGUSTE DE (Lat. *Thuanus*), a French historian, born in Paris, Oct. 8, 1553, died May 7, 1617. He was the 8d son of Christophe de Thou, first president of the parliament of Paris, and was destined for the church, but soon turned to the study of law, and was a pupil of Onjas and Hottman. In 1573 he accompanied Paul de Foix, the French ambassador, to Italy, where he continued his studies, and began to write a general history of his own time. On his return home, he was sent on a mission to the Netherlands; received the appointment of councillor in the parliament when scarcely 28 years old; and in 1581 was sent as a commissary to Guienne to administer justice. There he became acquainted with the prince of Condé, the young king of Navarre (afterward Henry IV. of France), and the celebrated philosopher Montaigne. Being recalled to Paris, he was made master of requests, and afterward *président à mortier* of the parliament of Paris, by Henry III., whom he served with zeal as commissary in Normandy and Picardy, presided over that part of the parliament which, upon the king's order, adjourned to Tours, and was one of the deputies to the states-general at Blois in 1589. Associated with Schomberg, he aided in bringing about a reconciliation between Henry III. and Henry of Navarre, and went to Germany and Italy to procure aid for them in men and money. Finding Henry IV. on the throne at his return, he adhered faithfully to him, was appointed by him grand master of the royal library, was one of the framers of the edict of Nantes, and supported the rights of the Gallican church by preventing the adoption in France of several decrees of the council of Trent. Although a Catholic by education and profession, he assisted in several of the meetings between the heads of his own church and those of the Protestants; accepted in 1601 the title of temporal father and patron of the Franciscans; and, notwithstanding all these extraneous offices, fulfilled his magisterial duties with the utmost punctuality, while he found leisure to prepare his great history. On the death of Henry IV. he was, in conjunction with Châteauneuf and Jeannin, appointed one of the directors of finance, but was refused by the queen regent the office of first president of the parliament, which had been promised him by the late king. This disappointment preyed upon his mind, and embittered his later years. He published in 1604 the first 18 books of his *Historia sui*

Temporis, which rapidly passed through 5 editions. He prepared a more complete one, which began to appear in 1616, and was not completed till after his death. Père Dupuy and Nicolas Rigault, improving the materials he had left, issued in 1620 the 7th edition, which consisted of 188 books, and embraced a period of 64 years, from 1543 to 1607. The best edition of his historical works is that of S. Buckley and T. Carte (7 vols. fol., London, 1783), which, beside the *Historiarum sui Temporis Libri CXXXVIII.*, contains his autobiography, letters, and various essays, with an appendix by Rigault bringing down the history to the death of Henry IV. This history, which is deservedly classed among the masterpieces of the kind, is written in exceedingly chaste Latin. It has been translated into French. De Thou also left some Latin poems: *Hieracosophion, sive de Re Accipitraria Libri III.* (4to., 1584); *Pœmata Sacra* (12mo., 1599); and *Posteritati, Poematum, Opus, &c.* (12mo., 1678).—His son, FRANÇOIS AUGUSTE, who succeeded him as grand master of the royal library, and was afterward named councillor of state, was a friend of Cinq-Mars, and died on the scaffold, Sept. 12, 1642, with that unfortunate favorite of Louis XIII.

THOUARS. See DU PETIT-THOUARS.

THOUVENEL, ÉDOUARD ANTOINE, a French statesman, born in Verdun, Nov. 11, 1818. He studied law, made a journey in the East, and published *La Hongrie et la Valachie, souvenirs de voyage et notes historiques* (1840). He then entered the bureau of foreign affairs in the ministry of Guizot, and in 1845 went to Brussels as attaché. In 1845 he was sent to Athens as secretary of legation, and after the recall of the ambassador was, in Jan. 1849, raised by Gen. Cavaignac to the dignity of minister with full powers, and acted as such during the negotiations of 1850 in regard to Don Pacifico. In Dec. 1851, he was called to the direction of political affairs in the foreign office, and remained in this position until 1855, when he was sent as ambassador to Constantinople. On May 8, 1859, he was made senator; and upon the disagreement between the emperor and Count Walewski in regard to the Italian policy, Thouvenel succeeded that minister, Jan. 5, 1860, in the department of foreign affairs. In this position he conducted in 1860 the diplomatic negotiations with England in regard to the Syrian expedition, and in regard to matters in Italy with Count Cavour, who ironically said of him: "This Thouvenel writes excellent despatches, true works of art. He makes a trade of diplomacy, as we do of politics." He still holds the station of minister of foreign affairs.

THRACE, in ancient geography, originally the name of that part of modern Turkey in Europe lying between the Danube, the Black sea, the sea of Marmora, the Grecian archipelago, the Struma, and a line, not well defined, connecting that river with the Danube. In

later times, however, that part of Thrace which lay between the rivers Strymon (now Struma) and Nestus (Karasu) was annexed to Macedonia by Philip, the father of Alexander, and the country N. of the Hæmus (Balkan) was made by the Romans a separate province under the name of Mœsia. Thrace, in the narrowest sense of the word, was bounded N. by the Hæmus, E. by the Euxine (Black sea), S. E. and S. by the Thracian Bosphorus (strait of Constantinople), the Propontis (sea of Marmora), the Hellespont (strait of Dardanelles), and the *Ægean sea* (archipelago), and W. by the Nestus. Two offshoots of the Hæmus, the Rhodope (Despoto Daghi), E. of the Nestus, and a parallel range near the Euxine, traversed it in a S. E. direction. It was watered, beside the Nestus, by the Hebrus (Maritza), its affluents the Artiscus (Tundja), Agriænes (Erkeneh), and others, and the Melas. The principal towns were Apollonia and Salmydessus on the Euxine; Byzantium (Constantinople) on the Bosphorus; Selymbria and Perinthus or Heraclea (Erekli) on the Propontis; Gallipolis (Gallipoli) and Sestos on the Hellespont, in the Thracian Chersonesus (peninsula of Gallipoli); Lysimachia, *Ænos* (Eno), Mesembria, Maronea, and Abdera, on the *Ægean*; and Philippopolis (Filibe), Hadrianopolis (Adrianople), and Trajanopolis, on the Hebrus. The towns on the sea coast were all Greek settlements. The district between the Strymon and Nestus, called Macedonia Adjuncta, contained Neapolis, Philippi, and Amphipolis. In the times of Herodotus and Thucydides, Thrace, in the wider sense, was peopled by numerous tribes, probably of the Gothic branch of the Indo-European family. Among these were the Getæ, Treres, Odrææ, Triballi, Daci, and Mœsi. They are described as powerful, warlike, and cruel. They purchased their wives and sold their children to exporting traders, tattooed their bodies, lived on booty and plunder, and were renowned as hard drinkers. They worshipped deities identified with Mars, Bacchus, and Diana, and had an oracle of Bacchus on a lofty summit of Rhodope. The tribes near the southern coast were more civilized, owing to the influence of the Greek settlers. At an early period, however, some of the Thracian tribes appear to have attained to a higher degree of culture than even the Greeks, their neighbors. Thus Orpheus, Linus, Musæus, and Eumolpus are said to have been Thracians, beside whom Thamyris and Zamolxis may be mentioned. We find fragments of the Thracian race also in parts of Asia Minor and central Greece.—The Thracians are said to have been conquered by Sesostris of Egypt, and subsequently by the Tencirians and Mysians. They were subdued by the Persians under Darius, but recovered their freedom after the reverses of Xerxes. Their most powerful native rulers were Sitaceus, king of the Odrææ, who fell in a battle against the Triballi in 428 B. C., and his nephew Seuthes, after whose death the Thracian kingdom was

split up in parts. Philip of Macedon conquered the greater part of it, and after the death of Alexander it was ruled by Lysimachus. It was subsequently annexed to Macedonia, and finally, with the latter, to the Roman dominions, though long continuing to be governed by native chiefs. After the division of the Roman empire it shared the fate of the eastern part.

THRALE. See PIZZI.

THRASHER. See THRESH.

THRASYBULUS. I. An Asiatic Greek, tyrant of Miletus, who lived about the middle of the 6th century B. C. During his reign Sadyattes and Alyattes, kings of Lydia, waged war for 11 years against Miletus. Alyattes, in setting fire to the crops of the Milesians, had destroyed a temple of Minerva at Assesus, and immediately afterward fell sick; and the Delphic oracle, when consulted upon his illness, refused to give a response until the temple should be restored. Alyattes therefore sent a herald to Miletus to ask for a truce while rebuilding the temple. Thrasybulus agreed to the truce, and, though in distress for provisions, made before the herald the greatest ostentation of plenty. This stratagem produced its desired effect, and Alyattes, who had expected to hear that the Milesians were reduced to the last extremity, hastily concluded a peace. For his celebrated advice to Periander, see PERIANDER. II. An Athenian, attached to the democratic party, and a friend of Alcibiades, died in 389 B. C. In 411 he was in command of an Athenian galley in the fleet at Samos, and joined the opponents of the oligarchical government of the 400, exacting an oath from the Athenians in the fleet to maintain the democracy. He was soon after made a general by an assembly in the camp, and procured the pardon and recall of Alcibiades. At the battle of Cynossema he commanded the right wing, and secured the victory by a sudden attack upon the Peloponnesians. In 407, with a fleet of 30 ships, he reduced most of the revolted cities on the coast of Thrace to submission, and about the same time was with Alcibiades elected one of the new generals. Banished on the establishment of the thirty tyrants, he seized with the aid of some Thebans the fortress of Phyle, and with 1,000 men occupied Piræus. After the accession of the ten he was defeated by Lysander and Libys, but, together with all who had joined him, was saved from punishment by the contrivance of Pausanias. In 395 he led an army to the assistance of the Thebans, then menaced by Sparta, and in 390 was sent with 40 ships to aid the Rhodians against Teutias, restored the Athenian interest in Byzantium, secured several new alliances, and reduced Methymna and other towns in Lesbos. Afterward sailing south, he anchored in the Eurymedon, near Aspendus in Pamphylia, when the inhabitants, exasperated by some act of his soldiers, fell upon him in the night and killed him. III. Tyrant of Syracuse, brother of Gelon and of Hiero I., the latter of whom he suc-

ceeded upon the throne in 467 B. C., supplanting his nephew, the rightful heir. In order to protect himself against his own people, whom he had exasperated by his cruelty and injustice, he gathered a large force of mercenaries, occupied two quarters of the city, Achradina and Ortygia, and harassed the citizens by frequent sallies. They at length assembled a large force, defeated him, and compelled him to leave Syracuse; and after a reign of only one year he retired in 466 to Locri in southern Italy, where he died, being the last of his dynasty.

THREATENING LETTERS, sent to persons for the purpose of extorting money, have been said to constitute a misdemeanor or criminal offence at common law. Blackstone says that threatening by letter (even without demand) to kill any of the king's subjects or to fire their houses, &c., was made high treason by a statute of Henry VIII. But the law of England on this subject is determined by more recent statutes. By 9th George I. and 27th George II. this offence was made felony, punishable by death; but, by 10th and 11th Victoria, ch. 66, the punishment was changed to transportation beyond the seas for life or any term not less than 7 years, or imprisonment not less than 4 years, and, if a male, public or private whipping. In many of the United States there are statutory provisions, punishing with great severity an attempt to extort money by means of a threatening letter. Generally, one who makes such a threat may be held to bail, or compelled to give security to keep the peace and be of good behavior. There have been several cases under these statutes, but they have usually turned upon questions of fact depending on the peculiar circumstances of the case, and not on questions of law. It may be said, however, that a threat, to be indictable, must be such as might naturally overcome a man of ordinary firmness and sagacity; and the money demanded under the threat must be money to which the sender of the letter has no right. In England, it would seem to be an offence at law to post up, on a placard or otherwise, a threatening notice; and it has even been held that a request to another to post up such a notice is indictable. The offence of sending a threatening letter is in law committed in the county to which it is sent, and the sender may be indicted in that county.

THRESHER. See **SHARK**.

THRESHING MACHINE, a machine for threshing and separating grain from the straw. The threshing floor of the ancients was a flat surface of ground covered with clay rolled smooth and hard. Sheaves of grain were spread evenly on this floor, and cattle driven over it until the grain was beaten out by the con-

stant tramping upon it. The Egyptians usually muzzled the ox while threshing, and the Greeks are said by *Ælian* to have had the filthy practice of besmearing the mouths of animals with dung to prevent their eating the grain. The flail, which is yet in common use by small farmers, is supposed to have been the first mechanical device for threshing. It is a very ancient invention, and the exact period of its origin is not known. Planks or timbers stacked over with pieces of flint or hard wooden pegs were used to some extent, but answered no good purpose. Michael Manzes, an East Lothian gentleman, is supposed to have been the first inventor of a machine for threshing, which was merely an adaptation of suitable mechanism to drive a large number of flails by water power. Though unsuccessful in practice, this machine attracted considerable attention, and in 1758 a Stirlingshire farmer named Leckie invented a rotary machine which consisted of a set of cross arms attached to a horizontal shaft, and the whole enclosed in a cylindrical case. It proved tolerably efficient in threshing oats, but was not adapted to wheat, as it knocked off the entire head from the straw without separating the kernels. Mr. Leckie having demonstrated the superiority of a rotary motion for this purpose, it was an easy matter to remedy the defects of his machine and perfect the invention. In 1786 Andrew Meikle, a Scotchman, made an improvement on Leckie's machine by substituting a drum or cylinder with projections on its surface formed by sticking in short pins, or otherwise. He also applied rollers, connected by suitable mechanism to the driving gear, for feeding in the straw. When operated, the drum was set in rapid motion by water or other power; the sheaves of grain, unbound and placed between the rollers, were fed in; and the projections, revolving with great velocity on the periphery of the drum, beat out the grain from the heads and partially separated it from the straw. A patent was procured in Great Britain in 1788, when Mr. Meikle constructed the first working machine, and added many new improvements, among which was the attachment of a fan mill, by which means the grain was separated and cleaned from both straw and chaff. Though an invention of vast importance, saving annually millions of dollars in manual labor, and immensely increasing the product of grain throughout the civilized world, the simplicity of the threshing machine and the perfection of Meikle's inventions left little room for great modern improvements. The most prominent American inventor connected with this machine is Mr. Pitts, who considerably improved the method of separating the grain and straw after being threshed. His patent has long since expired, and his improvement is very generally in use. Threshing machines are constructed of various sizes, from one to ten horse power inclusive. The duty of a good two horse power machine is said to be 300 bushels of oats or 100 bushels

of wheat per day of 10 hours. The larger machines usually have the fan mill attached, delivering the grain perfectly clean and ready for the market; but the smaller only thresh the grain from the straw, requiring the separate operation of the fan mill to clean it from the chaff.

THRIFT (*armeria vulgaris*, Willd.), a pretty herbaceous plant, with linear smoothish leaves, somewhat triangular at base and clustered around the short stem close to the ground. The pale purple flowers in heads, proceeding from a scaly membranaceous involucre, are supported on dwarf scapes. There are two or more distinct varieties, one with broader leaves and taller flower scapes, and another with red flowers, which is more attractive when in blossom. The thrift is a native of the Alps of continental Europe, and of the most northern parts of Canada. It was early introduced into the British flower gardens for making edgings and borders. It is found to prefer a soil in which a little peat is mixed.

THROCKMORTON, a new N. W. co. of Texas, drained by the Brazos river and its affluents; area, about 500 sq. m.; pop. in 1860, 124, none of whom were slaves. The surface is undulating and the soil highly fertile. There is an abundance of fine timber and ample supply of water for manufacturing purposes. The Comanche Indians still occupy a portion of the county. Capital, Camp Cooper.

THROCKMORTON, SIR NICHOLAS, an English statesman, born in London about 1513, died there, Feb. 12, 1571. His ancestors had filled high offices in the state for centuries. He was page to the duke of Richmond till 1536, was afterward sewer to Henry VIII., and headed a troop at the siege of Boulogne. Distinguished in the Scottish campaign under Somerset, he was soon after knighted, received valuable manors and appointments, and sat in parliament as member for Northampton. He was present at the death of Edward VI. in 1553, and, though a Protestant and aware of the movement in favor of Lady Jane Grey, favored the accession of Mary. Arrested in the following year as an accomplice in Sir Thomas Wyatt's rebellion, he conducted his own defence, disputed every point with the counsel and the bench, and was acquitted by the jury. It is certain that he was privy to if not implicated in the rebellion, and the judges remanded him to the tower on the ground that the verdict was contrary to law; and the jurors were called before the star chamber, where four expressed contrition and the others were fined and imprisoned. An elaborate and copious report remains of this trial. He was released in 1555, went to France till 1556, and privately visited the princess Elizabeth at Hatfield, after whose accession he received successively the offices of chief butler of England and of chamberlain of the exchequer. As ambassador to France from 1559 to 1563, he favored the policy of Cecil, and intrigued to foment the civil religious war; was sent to Scotland in 1565 to

remonstrate with Mary against her marriage with Darnley; was imprisoned in 1569 for having favored a marriage between Mary and the duke of Norfolk; and though soon released, never regained Elizabeth's confidence.

THRUSH, the common name of a very large family of dentirostral birds, which contains some of the finest songsters in various parts of the world. The bill is of moderate length, rather stout, slightly convex and keeled above, with sharp and notched tip; at the base of the upper mandible on each side of the gape is a row of bristles of much less size than in the flycatchers; nostrils at the base of bill, partly protected by a membranous scale; wings tolerably long, broad, usually rounded at the end, with the 1st quill very small; legs rather short and stout; tarsi compressed, covered in front by a single scale in the typical genus *turdus* (Linn.); tail moderate. The food consists of insects, worms, berries, and fruits, and sometimes mollusks; they move on the ground by hopping on both feet at once. The family of *turdidae* or thrushes is divided by Gray into the sub-families *formicarinæ* or ant thrushes, with rather long legs, living principally on ants, and found in the tropics of both hemispheres; *timolina* or babblers, with a more curved bill, and tarsi long and strong, so named from the chattering made by their flocks, inhabiting the old world; *oriolina* or orioles, from the old world (see **ORIOLE**); *pycnonotina* or bulbuls, with a short and much curved bill, also from the old world; and *turdina* or true thrushes, which alone can be noticed here. Two species of the genus *mus* (Boie), placed by Cabanis in the family *liotrichidæ*, have been described under **CAT BIRD** and **MOCKING BIRD**.—There are more than 100 species of the genus *turdus* described, having the characters given above; they are found in all parts of the world, and are more or less migratory and shy; some frequent forests, others the thickets of field and meadow, and others rocky districts; the nest is made of coarse grasses and mosses, usually lined with mud and soft plants, and is placed on bushes or trees; the eggs are 5 or 6 in number; the flesh is delicate and good eating. Several species have been already noticed under **BLACKBIRD**, **FIELDFARE**, and **ROBIN**. Among the American species may be mentioned the wood thrush (*T. mustelinus*, Gmel.), 8 inches long and 1½ in alar extent; the form is stout, the tail nearly even, and the 8d and 4th quills the longest; the general color is rufous brown above, brightest on the head, and olivaceous on the tail; pure white below, with numerous blackish spots on breast and sides; legs yellow, bill brown, yellowish at base. It is found in the eastern United States to the Missouri river, and south to Guatemala. This was Audubon's greatest favorite, as its sweet notes enlivened him in the solitary and dense forest at early dawn after an uncomfortable and stormy night; the notes are few, but powerful, clear, and mellow, rising and falling in gentle cadences; they are

especially pleasing at sunset, when several of these charming songsters seem to challenge each other to sing their best; the food consists of berries and small fruits, and insects; the flight is elevated. The eggs are uniform light blue; the young are easily raised from the egg, and they sing well in captivity; the flesh is very delicate and juicy.—The hermit or solitary thrush (*T. Pallasii*, Cab.) is $7\frac{1}{2}$ inches long and $11\frac{1}{2}$ in alar extent; it is yellowish olive above, rufous on the tail and rump; below white, with black spots on breast; tibiae and sides yellowish olive brown. It is found in eastern North America to the Mississippi river; it is a constant resident in the southern states, preferring the darkest, most swampy, and most secluded canebrakes along the Mississippi; its flight is short, low, and gliding; its song is only a single soft and plaintive note; the nest is built lower on the trees than that of the wood thrush, not so firmly saddled on the branches, and smaller; the eggs are light blue, with dark dots at the larger end; it raises 2 broods in the south; it feeds on berries and fruits. Wilson's or the tawny thrush (*T. fuscescens*, Steph.) is $7\frac{1}{2}$ inches long and $11\frac{1}{2}$ in alar extent; uniform yellowish red above; throat and upper neck yellowish, with very indistinct spots on the latter; rest of lower parts whitish. It is found in eastern North America to the Missouri, and north to the fur countries; its song is similar to that of the wood thrush, but less powerful and with more trills and variations; it prefers dark woods and moist places, feeding on beetles and berries, passing most of the time on the ground, where it hops with great agility; the eggs are pale greenish blue; only one brood is raised in a season. The olive-backed thrush (*T. Swainsonii*, Cab.) is 7 inches long and about 12 in alar extent; dull greenish olive above; the sides of the head, breast, and throat tinged with reddish yellow, with a ring of the same around the eyes; breast with very distinct dark brown spots, and rest of lower parts white. It is found over eastern North America to the Black hills, north to Greenland, south to Mexico and Peru, and is accidental in Europe and Siberia. Several other species are found on the Pacific side of the continent.—Of the European species, the largest is the missel thrush (*T. viscivorus*, Linn.), 11 inches long; it is light grayish brown above, the fore part of the head grayish and the rump shaded with ochrey yellow; secondary coverts and tail feathers tipped with grayish white; a cream-colored band from bill over eyes; below yellowish white, each feather tipped with a black spot, largest and transversely oblong on breast, smaller and triangular on neck. It frequents woods and coopes, in small straggling flocks, and is shy and vigilant; it feeds chiefly on berries, especially those of the mistletoe (whence its common name), in this way remarkably assisting in the diffusion of this plant. The song of the male resembles that of the blackbird, and is heard as early as February, before the appearance of

the leaves, and even during storms, whence its name of storm cock; it is very bold in the spring, driving away other birds from the neighborhood of its nest. The eggs are 4 or 5, $1\frac{1}{2}$ by $\frac{3}{4}$ of an inch, flesh-colored with irregular scattered spots of brownish red; 2 broods are generally raised in a season; it has been seen to carry off small birds to its nest to feed its young, like the shrike and jay; the flesh is good. The song thrush, throatle, or mavis (*T. musicus*, Linn.) is 9 inches long, yellowish brown above, tinged with red on the head; secondary coverts tipped with reddish yellow; fore part of neck and breast yellowish, each feather terminated by a triangular brownish black spot; lower wing coverts reddish yellow. It frequents lightly wooded regions and gardens, in the latter doing good service by destroying snails, obtaining the animal by breaking the shell against a stone; it is one of the finest of European songsters, singing from early spring to autumn, in the morning and evening, from the top of a bush or tree; Macgillivray highly praises its melody. It was one of the birds used by Roman epicures in their extravagant dishes of the brains and tongues of singing birds; it is sometimes seen now in the markets, and its flesh, especially in the beginning of winter when the food consists of snails and worms, is very fat and juicy. Several other fine singers of the genus are found in various parts of the old world.—There are two birds generally called thrushes in the United States, which deserve mention here; one is the brown thrush or thrasher, placed by Cabanis and Baird in the family *Ictrichida*, sub-family *minims* (with the cat and mocking bird), and genus *Merulopterus* (Reich.). This bird (*M. rufus*, Reich., or *T. rufus*, Linn.) is $11\frac{1}{2}$ inches long and 13 in alar extent; brownish red above; below pale rufous white, thickly streaked with dark brown, and tinged anteriorly with reddish; 2 white bands on the wings; inner surface of wings and inner edge of primaries cinnamon; tail rufous. It is found over eastern North America to the Missouri, and perhaps to the high central plains; it is a constant resident in the southern states, and is almost as numerous as the robin; it migrates by day, singly, with a low and heavy flight. The song is prolonged, loud, varied, and melodious, surpassed, in the opinion of Audubon, only by that of the mocking bird. The eggs are 4 to 6, dull pale buff, with numerous brown dots; 2 broods are raised annually in the southern states; it breeds well in aviaries, and the young are raised like mocking birds, singing well and very active in confinement. It is a bold and powerful bird, chasing cats, dogs, and foxes, not afraid of hawks and snakes, and savagely fighting with its rivals in breeding time; it will attack and kill small birds in the same cage with it; both sexes incubate, and bravely defend their nest and young; the food consists of insects, berries, and fruits of all kinds. The water thrush (*Scotus borealis*, Nutt.; *T. aquaticus*, Wils.)

is placed by the most recent ornithologists in the family *sylicolida* or warblers; it is 6½ inches long and 9¼ in alar extent; olive brown above with a green shade; beneath pale sulphur yellow, brightest on the abdomen; the other parts thickly streaked with olivaceous brown, and blackish on the breast. It is found throughout the eastern United States to the Missouri and south to Central America, and perhaps to Brazil. This, as also the Louisiana water thrush, considered by some as a distinct species and by others as a mere variety, is an exquisite songster; it is rather shy, wading in and about water in search of insects; the eggs are flesh-colored, with dark red spots on the larger end; the flesh is very fat and juicy in the southern states in winter.

THUANUS. See THOU, JACQUES AUGUSTE DE.

THUCYDIDES, a Greek historian, born in Athens about 471 B. C., died about 400. He was the son of Olorus, and was probably connected with the family of the great Miltiades and Cimon, and is said to have been connected also with that of Pisistratus; but the few facts that are known with any certainty of his life are derived from his own writings. The story that at the age of 15 he heard Herodotus read his history at the Olympic games, and was affected to tears, is at least doubtful, as is also the statement that he studied the art of rhetoric under Antiphon. He tells us that he owned gold mines in that part of Thrace opposite Thasos, from which in after times Philip of Macedon obtained the treasure used in the subjugation of Greece. In 424 B. C., the 8th year of the Peloponnesian war, he was the commander of an Athenian squadron of 7 ships, and charged with the general authority on the coast of Thrace. The Spartan general Brasidas was anxious to get possession of the important city of Amphipolis, defended by Eucles, the colleague of Thucydides; and fearful that the Athenian admiral, from his property and his influence in Thrace, would be enabled to rouse that country against him in defence of the city, he offered to the garrison the most favorable terms of capitulation. Thucydides, who had been stationed at Thasos, as soon as he received the message set sail with his whole force, and reached Eion, 8 m. from Amphipolis, that same evening. The city he found had already surrendered, but he succeeded in repelling an assault made by Brasidas against Eion both by land and water. The capture of Amphipolis was a great blow both to the prosperity and pride of Athens, and the two generals charged with the defence of the city were obliged to undergo punishment, either for their ill success or for their neglect of duty. Thucydides was condemned to exile, on the proposition of Cleon. Modern historians almost universally represent the accused man as innocent, and as suffering from the consequences of a misfortune, not of a fault; but Grote defends the conduct of the Athenians on the ground that the general had been charged with the de-

fence of the Thracian coast, and especially of Amphipolis, and was culpably wrong in not having taken care to be near enough the city to render it efficient and immediate aid in case of attack. Thucydides passed 20 years in exile, spending much of the time in Thrace; but he must also have visited various other parts of Greece, and it is certain from his own writings that he frequently visited the states under Laodæmonian rule. He returned to Athens about the time the city was freed by Thrasybulus. The accounts of the time and manner of his death are uncertain, but among the ancient writers there seems to have been a general impression that he died violently. According to Pausanias, he was assassinated after his return; according to Plutarch, he was said to have been killed in Thrace, though his remains were carried to his native city.—The work by which Thucydides is known is the history of the Peloponnesian war, for which he carefully collected the materials during its progress. It is divided into 8 books, the first of which is introductory to the history. Thucydides was not only the greatest historian of Greece, but he created a kind of historical writing in which he has never been surpassed and rarely rivalled. The great struggle between the republics of Athens and Sparta for the hegemony of Greece is the leading idea of his work, in which the interest of all events centres. Every thing which illustrates this idea is carefully related, no matter how unimportant in itself; every thing which does not bear upon the great contest, no matter how important, is passed over entirely or thrown dimly into the background. The accuracy and truthfulness of the history, and the care and skill with which the conflicting evidence has been sifted, have never been attacked. It is in narration, in the vivid description of events, that Thucydides is especially conspicuous. "He was," says Macaulay, "a perfect master of the art of gradual diminution. His history is sometimes as concise as a chronological chart; yet it is always perspicuous. It is sometimes as minute as one of Lovelace's letters; yet it is never prolix. He never fails to contract it and to expand it in the right place." Although evidently a man who recognized the importance of religious influences, he was never the slave of the superstitions of his times; and with a quiet irony he remarks that of all the prophecies uttered at the commencement of the war, that one only came true which declared that it would last thrice 9 years.—The first edition of Thucydides was published by Aldus at Venice in 1502. Of the numerous succeeding editions, the best are those of J. Bekker (8 vols., Berlin, 1821), Haack (2 vols. 8vo., Leipzig, 1820), Poppe (10 vols. 8vo., Leipzig, 1821-'38), and Arnold (8 vols. 8vo., Oxford, 1830-'35). There have been English versions by Nicolls (London, 1550), by Hobbes, by W. Smith (1758), by Bloomfield (1829), and by Dale (1856).

THUGS (Hindustanee, *Phugna*, to deceive), a sect of assassins in India, now nearly exter-

nated by the British government. Their atrocious practices were not followed so much for the sake of plunder, or for the gratification of a malicious nature, as from religious motives. They were the worshippers of the goddess Kali, the divinity who presided over impure loves, sensual indulgences, and death. One of the sacred books of the Hindoos, of the second grade, the *Kalika Purana*, describes their practices with the utmost accuracy. The members of the sect belong to all the different castes, and each has its functions to perform. The gangs were from 80 to 800 in number, and they were divided into various classes under a *junadar* or *sirdar*, their leader, and a *guru* or teacher. The classes were the spies, who were learners; *bhuttotes*, stranglers; *sothas*, entrapers, who were sometimes women; and *lu-ghaees* or grave diggers. They usually assumed the dress of merchants or pilgrims, and often craved the protection of those whom they intended to destroy. Their usual instrument of destruction was the handkerchief or *rumal*, with which by a dexterous movement they strangled their victims. The spies having informed them of the particulars relative to the route, habits, and circumstances of their intended victims, the members of the gang travelled in such lines as to be near each other, and the entrapers by artful management attracted them to a spot remote from dwellings, where the stranglers executed their office; and having stripped them of whatever they possessed, the grave diggers buried them, with such precautions as generally to prevent discovery. The plunder received was divided, one third to the widows and orphans of the sect, one third to the goddess Kali, and the remainder to the partners in the assassination. After a murder the Thugs who had committed it united in a sort of sacrament called *tapounes*, eating consecrated sugar. Their deities were carefully consulted before going on their expeditions, and unless the omens were favorable the Thug would not go. Neither women nor old men were victims. Europeans were never killed, because there would be more danger of detection. There were also bands of Mohammedan Thugs, of the sect of Mooltanees, and it is possible that at the first the system of *thuggee*, as they term it, originated with Mohammedan banditti, though it afterward became more a Hindoo than a Mohammedan practice, and the words used are of Sanscrit origin. They were found in all parts of India. In the Deccan they were called *phansigars* or noosers. Hyder Ali and Tipoo Sultan both attempted to exterminate them, and the English government sought to suppress them as early as 1810; but it was not till the administration of Lord William Bentinck (1827-'35), who appointed Capt. Sleeman to this service, that their gangs were successfully broken up. Between 1826 and 1835, 1,562 persons were condemned as Thugs, their families put under surveillance, and their children educated to virtuous habits and taught

trades by which they might obtain an honest livelihood. In 1836 the government published, for judicial purposes, a work called "*Ramaseena*, or a Vocabulary of the peculiar Language used by the Thugs," written by Capt. (now Col.) Sleeman. Full accounts of this tribe of assassins are to be found in Thévenot's travels, in "The Confessions of a Thug," by Capt. Meadows, and in vol. xiii. of "*Asiatic Researches*."

THULE, the name given by the ancient navigator Pytheas, who flourished about the time of Alexander the Great, to an island in the northern ocean, which he discovered after a voyage of 6 days in a northerly direction from the Orcaades (Orkney islands). Modern geographers have differed in opinion as to the precise locality of the island, and it has been doubted whether any definite country is alluded to. The ancients generally applied the name to the most northern part of the habitable world, whence the phrase *ultima Thule*. Iceland, which has been frequently designated as the island discovered by Pytheas, seems too remote from the continent to have been visited by so early a navigator, and the more general opinion inclines to Mainland, the largest of the Shetland group. Some consider Norway the *ultima Thule*; and others, among whom is Malte-Brun, make it identical with Jutland.

THÜMMEL, MORITZ AUGUST VON, a German writer, born near Leipsic, May 27, 1788, died Oct. 26, 1817. He studied at the university of Leipsic, where he became intimately acquainted with Gellert, Weisses, Rabener, and Kleist. In 1761 he received an appointment in the service of the hereditary prince Ernest Frederic of Saxe-Coburg, who on his accession to the throne made him aulic councillor and in 1768 minister. In 1768 he resigned his office, and spent the remainder of his life partly at Sonneborn near Gotha, and partly in travelling. His principal works are: *Wilhelmine* (1764), a comical epic; *Inoculation der Liebe*, a poetical narrative (1771); and *Reise in die mittägigen Provinzen von Frankreich* (10 vols., Leipsic, 1791-1805), a novel containing many reminiscences of his own travels. A posthumous work by him, *Der heilige Kilian, oder das Liebespaar*, was published by Hempel in 1819. The first collective edition of his works was published by Thümmel himself (6 vols., Leipsic, 1812 *et seq.*); the last and most complete one in 1844, in 8 vols. A life of Thümmel was published by Gruner (Leipsic, 1819).

THUNBERG, CARL PETER, a Swedish naturalist, born in Jönköping, Nov. 11, 1743, died Aug. 8, 1828. At the university of Uppsala he became a pupil of Linnæus; and in 1771, a year after graduating, he accepted the situation of surgeon in one of the Dutch East India company's vessels, with the intention of undertaking a botanical survey of Japan. For the purpose of learning the Dutch language, he passed three winters at the Cape of Good Hope; and between 1778 and 1779 he resided principally in Java and Japan. Returning to

Sweden in 1779, he was appointed in 1784 professor in the chair of botany formerly occupied by Linnæus, which he retained until the close of his life. The results of his observations in Africa and Asia were given to the world in a series of elaborate works, of which the first, entitled *Flora Japonica*, &c. (8vo., Leipzig, 1784), contained a description of Japanese plants, including many new ones. In 1788-'91 appeared a general account of his travels under the title of *Reise uti Europa, Africa, Asia, forattad åren 1770-'79* (4 vols. 8vo., Upsal), which was within a few years republished in German, English, and French. His remaining works comprise *Prodromus Plantarum Capensium* (Upsal, 1794-1800); *Icones Plantarum Japonicarum* (Upsal, 1794-1805); *Flora Capensis* (Upsal, 1807-'18); and an immense number of memoirs on subjects suggested by his researches in Africa and Asia, which were published in all the principal scientific journals of Europe. He was, beside, the author of nearly 100 academical dissertations published at Upsal between 1789 and 1818. At the time of his death he was an honorary member of 66 learned bodies.

THUNDER. See **LIGHTNING.**

THURGAU, or **THURGOVIA**, a canton in the N. E. of Switzerland, bounded N. and N. E. by the Rhine and the lake of Constance, separating it from Schaffhausen, Baden, Württemberg, and Bavaria, S. E. and S. by the canton of St. Gall, and W. by Zürich; area, 384 sq. m.; pop. in 1860, 90,847. The surface is comparatively level, but numerous hills traverse the country in different directions, the height of which nowhere exceeds 1,000 feet above the level of the lake of Constance. The drainage belongs to the basin of the Rhine, toward which it flows by the Thur and its tributaries, and also by the lake of Constance, including the Untersee. The climate in the S. W. is severe, but in the other parts of the canton it is temperate. The soil is not very productive. Fruit is extensively grown, and the vine is cultivated in many places and produces wine of good quality. About $\frac{1}{4}$ of the surface is covered with forest. Some linen and cotton goods, ribbons, lace, hosiery, and canvas are manufactured. There is an extensive trade, greatly facilitated by the Rhine and Lake Constance. About $\frac{1}{4}$ of the inhabitants are Protestants, and numerous schools are established throughout the canton. The executive power is vested in a council of 6, who hold office for 6 years. The grand council or legislature consists of 100 members, half of whom retire every year. It is presided over by 2 *Landammans* chosen annually. Capital, Frauenfeld.

THURINGIA (Ger. *Thüringen*), a central region of Germany, between the Hartz mountains on the N. and the Thuringian Forest on the S., the river Saale on the E. and the Werra on the W., the principal parts belonging to the Prussian province of Saxony, to Coburg-Gotha, Weimar-Eisenach, Schwarzburg-Sondershausen, and Schwarzburg-Rudolstadt. The Thu-

ringians are mentioned among the allies of Attila in the middle of the 5th century. Their country was afterward subdued by the Franks and Saxons. The former ruled it for some centuries through dukes and margraves. Under the Saxon emperors several Thuringian counts or landgraves obtained a kind of semi-independence. Louis the Jumper, son of Louis the Bearded, warred against the emperor Henry IV. in the 2d half of the 11th century, and several of his successors added to the possessions of the house. A long war of Thuringian succession was waged about the middle of the 13th century, the termination of which left the principal parts of Thuringia in the possession of the margrave Henry of Meissen. After numerous vicissitudes and intestine struggles, the country was divided in 1485 between Albert and Ernest, the sons of Frederic the Mild, the founders of the Albertine and Ernestine lines of the house of Saxony, and has since that time not been reunited.—The Thuringian Forest (Ger. *Thüringervald*), which bounds it on the S. W. and S., is a narrow and wooded mountain range, rising in some parts to the height of upward of 8,000 feet, and extending some 70 m. in length, not including numerous northern offshoots toward the Hartz. In the S. E. it approaches the Fichtelgebirge, and in the S. W. the Rhön, from which it is separated by the valley of the upper Werra. The inhabitants are chiefly engaged in mining, grazing, and manufactures. The territory covered or traversed by the Thuringian Forest is included in Prussian Saxony, Hesse-Cassel, Weimar-Eisenach, Coburg-Gotha, Meiningen, Schwarzburg-Rudolstadt, and the Reuss principalities.

THURLOW, EDWARD, lord, an English jurist and statesman, born at Little Ashfield, near Stowmarket, Suffolk, in 1732, died in Brighton, Sept. 12, 1806. He was educated at Caius college, Cambridge, where he gained no distinction as a scholar, and in 1754 was called to the bar by the society of the Inner Temple. He immediately entered upon a lucrative practice, which, after his appointment in 1761 as king's counsel, was exceeded by that of only 2 or 3 of the most eminent advocates of the time. In 1768 he was elected to parliament as a supporter of Lord North; in 1770 he was appointed solicitor-general, in 1771 attorney-general, and in 1778, as a reward for the zeal and energy with which he advocated the policy of the government respecting America, he was made lord chancellor, and raised to the peerage as Baron Thurlow. By the express command of the king, whose confidence he had gained to a remarkable degree, he retained the office of lord chancellor in the Rockingham and Shelburne administrations, which succeeded that of Lord North, notwithstanding he was politically opposed to his coadjutors, and lost no opportunity to defeat their leading measures. The confusion thereby caused in the cabinet led to the withdrawal of Fox; and in the coalition ministry which succeeded, it was expressly stipu-

lated that Thurlow should not hold a seat. He still remained in confidential relations with the king, and upon the accession of Pitt to power, in Dec. 1783, received again the great seal, which he held for 9 years. At first he acted apparently in harmony with his colleagues; but having been suspected, after the king's insanity in 1788, of tampering with the prince of Wales and the whigs, he was looked upon with distrust by Pitt, for whom he in turn entertained a cordial dislike which he was at no pains to conceal. Gradually he began, as formerly under the Rockingham administration, to oppose certain measures of the cabinet, and the disturbance thus created led to his removal from office at the express request of Pitt, and with the ready consent of the king, a result which deeply mortified him. He never afterward held office or took a leading part in politics; and having no personal influence, he soon sank into comparative insignificance, notwithstanding he is said to have been confidentially consulted by members of the royal family until near the close of his life. He was a man of overbearing and passionate character, a bully rather than a debater in parliament, though occasionally an impressive and eloquent speaker.

THURN AND TAXIS. See *Post*, vol. xiii. p. 512.

THURSDAY, the 5th day of the week, the *dies Jovis* of the Roman calendar, and sacred in the northern mythology to the thunderer Thor, for whom it is named. In German it is called *Donnerstag* (thunder day).

THURSTON, a S. W. co. of Washington territory, bounded N. E. by the Nisqually river and E. by the Coast range; area about 400 sq. m.; pop. in 1860, 1,507. Much of the surface is mountainous, but there are several rich valleys which produce wheat, corn, oats, and other grains and potatoes in great abundance. An arm of Puget's sound extends into the N. E. part, and the line of Gov. Stevens's proposed Pacific railroad passes through the county. It has 2 churches and a newspaper. Capital, Olympia, which is also the capital of the territory.

THYESTES. See **ATREUS**.

THYLACINE, or **POUCHED WOLF**, a marsupial animal of the dasyurine family, and genus *thylacinus* (Temminck) or *peracyon* (Gray), peculiar to Tasmania; both of the generic names indicate the possession of the pouch characteristic of the order. In this genus the dentition is: incisors $\frac{3}{1}$, the outer slightly the largest; canines $\frac{1}{1}$, large, simply conical, the upper separated from the incisors by a deep concavity in which the apex of the lower is received when the jaws are closed, in this differing from carnivora proper, in which the lower canines pass outside of the upper jaw; premolars $\frac{3}{1}$, separated from each other; molars $\frac{1}{1}$, with a large central cusp, and 2 smaller, one in front and the other behind it. The humerus has the inner condyle perforated, the hind feet have no inner toe, and the marsupial

bones are absent, represented only by fibrocartilage; the female has a distinct pouch, with 4 mammae. Only one species is described, the dog-headed thylacine (*T. [P.] Harrisii*, Temm.), about the size of a young wolf, or 8 $\frac{1}{2}$ feet long, with a tail 20 inches additional, and a height at the shoulders of about 23 inches; the head is dog-shaped, with narrow and elongated muzzle; ears short, pointed, very broad at the base, and well covered with hair on both surfaces; eyes full and black, with a nictitating membrane; long black bristles on the upper lip, and a few on the cheeks and above the eyes; the claws stout, short, and brown, the bottoms of the feet with large, very rough pads. The fur is short and close, waved and slightly woolly; the general color is grayish brown, paler below, with 12 to 14 transverse black bands on the back, longest and widest posteriorly; pale around eyes, and edge of upper lip white; tail with short fur, with longer hairs at under side of apex; rusty red about the pouch. From its general resemblance to a wolf or large dog, some have placed it among carnivora, and Swainson ranked it with the cats; the legs are shorter in proportion than in the wolf, and the gait is semi-plantigrade. It is a wild and shy animal, inhabiting the caverns and dismal glens of mountainous districts; inactive during the daytime, probably from imperfect vision, it preys at night upon the smaller marsupials, and in former years attacked sheep to the considerable loss of the colonists; it is sometimes so large as to be a match for several dogs, and is the most formidable of the Australian quadrupeds; it is rare except in the most inaccessible regions; specimens have been exhibited alive in the zoological gardens of London.—Among the fossil remains of the caves of Wellington valley, New South Wales, Prof. Owen has described parts of lower jaws of what he calls *T. epelous*, differing from existing ones in their greater depth. In the secondary schists of Stonesfield has been discovered the genus *thylacotherium* (Owen), known by the lower jaw, which has 6 incisors, 2 moderate canines, 6 false and 6 true tricuspid molars; the *T. Prevostii* (Ouv.) was about the size of a rat. An allied genus from the same strata is *phasciotherium* (Broderip), of somewhat larger size.

THYME (*thymus*, Linn.), an aromatic herb used in culinary processes. It belongs to the natural order of *labiata*, and the genus comprises about 80 species, mostly natives of Europe, all undershrubs with pretty purplish flowers. The common or garden thyme (*T. vulgaris*, Linn.) has an upright stem about a foot high, clothed with soft hairs, sessile, linear, or ovate-lanceolate, acute leaves, with revolute edges in clusters in the axils; the flowers in cymes, small; calyx hirute, strongly ribbed, punctate; corolla pale purple. It is a native of S. W. Europe, growing on bare hills and in dry plains, but has been long known in the kitchen garden, and is readily cultivated. There are several varieties, such as the broad-leaved, the

variegated-leaved (much preferred for its beauty), and the golden or yellow-leaved, with a citron-scented smell. The last named is continued by cuttings or slips of the root, only the normal condition of the plant being certain from seeds. The wild thyme or mother of thyme (*T. serpyllum*, Linn.) has a procumbent habit, with half-woody stems rising only about 8 inches high; its leaves are ovate, blunt, petiolate, a little ciliate at base; the flowers usually purple, but sometimes white, constituting a permanent variety. The wild thyme affects certain kinds of pastures and dry heaths, completely overrunning them, and its presence indicates soils peculiarly adapted to sheep husbandry. It has likewise become a naturalized plant in eastern Massachusetts and in Pennsylvania.—The thymes contain carminative properties, but are not much esteemed in medicine. A volatile oil is distilled from the garden and wild thyme. Bees are very fond of this plant, and the honey obtained from it is of superior quality. The thyme of Mt. Hymettus is celebrated.

THYMUS GLAND (Gr. *Thymos*), one of the vascular or ductless glands, situated, in the human subject, in the upper part of the anterior mediastinum, extending in childhood from the thyroid gland to near the diaphragm, but becoming atrophied after the age of puberty. It is oblong, bilobed, flattened from before backward, bifurcated at each end, with a thoracic and a cervical portion on each side, the general cavities of which communicate with each other; it is gland-like in structure, soft, grayish white, covered with a capsule of areolar tissue, which sends prolongations inward, dividing it into unequal lobules; its cavities, when fully developed, contain corpuscles, apparently nuclei of glandular cells, secreting elements, but without any secreted product. It rests upon the trachea, thyroid and subclavian veins, superior vena cava, and arch of aorta, having in front of it the sterno-hyoid and sterno-thyroid muscles and the upper part of the sternum. It receives a very large supply of blood during the period of its functional activity from the internal mammary and thyroid arteries, and other vessels in the neighborhood; its lymphatics are large, communicating directly with the vena cava. It first appears as a single tube, closed at both ends and filled with granular matter, from which spring buds or branches, which at the period of complete development form an assemblage of hollow glandular lobules whose cavities communicate with a central reservoir having no outlet. It is generally stated that this gland attains its greatest development during the latter part of foetal life, and it has been accordingly considered as peculiarly connected with the embryonic condition; but recent observations show that its most rapid growth is, in the human infant, soon after birth, when also its functional activity is greatest; it soon becomes less active, growing with the rest of the body till about the age of 2 years, then remaining stationary for a few

years, and gradually changed about the time of puberty into a mass of fat, the corpuscles of its interior being developed into fat-secreting cells; this change of function is most remarkable in hibernating mammals and reptiles, in which the organ continues to grow till adult age. It is about the same in the anthropoid apes as in man, and is remarkably developed and may be well studied in the calf, in which, and in the lamb, it is called the sweetbread; it exists in mammals, birds, and in most reptiles, but not in the larvæ of batrachians, the perennibranchiate amphibians, nor fishes. Simon (who, with Sir Astley Cooper, has made the most careful researches on this organ) considers it coextensive with pulmonary respiration, and says it fulfils a use "as a sinking fund in the service of respiration;" this view he thinks is confirmed by its size in hibernating animals, in which the breathing process is reduced to an extremely low ebb, yielding fatty fuel for respiration. Other physiologists, admitting this in the case of hibernation, maintain that it performs the different function in the rapidly growing child of elaborating plastic material. The large amount of blood sent to it indicates an active process of cell growth, the products of which are discharged into the current of the venous circulation, probably preparing, according to Carpenter, albuminous material for higher uses in the formative operations of the system; it may also act as a storehouse of nutritive material which may be drawn upon as the system requires it during growth, and supply germs of cells which are ultimately to become blood corpuscles. In over-driven lambs it rapidly diminishes, and gradually increases again with rest and plentiful food. Its diseases are very little known; but it is certain that the suffocative paroxysms of the so called "thymic asthma" of Dr. Kopp have no essential connection with an enlarged thymus gland.

THYROID GLAND (Gr. *Thyros*, a shield, and *eidos*, form), one of the vascular or ductless glands, situated on the anterior and lower part of the larynx, in front of the upper rings of the trachea. It is composed of 2 elongated ovoid lobes, flattened from before backward, united or separate, but generally connected by a transverse portion; it is covered by the muscles of the front of the neck. The tissue is tolerably firm, brownish and yellowish red, formed of lobes and lobules, consisting essentially of an aggregation of closed gland vesicles imbedded in condensed areolar tissue; these contain a small amount of a fatty albuminous fluid, and do not communicate with any common reservoir; among the vesicles are nucleated corpuscles or epithelial cells; it receives 4 arteries from the subclavians and the carotids, nerves from the pneumogastric and the sympathetic, and lymphatics communicating with the glands of the neck. The vascular supply is great, and forms a very minute capillary plexus on the membrane of the ves-

cles; it is developed as in other ductless glands (see THYMUS GLAND), like which it is relatively larger in intra-uterine existence and in infancy than in after life. Its products are discharged into the venous blood, and probably, like the thymus, it prepares albuminous material for the higher formative operations, and contributes to the supply of new blood corpuscles; Simon considers it a diverticulum to relieve the cerebral circulation, as the spleen is to the portal, from the proximity of the origin of both sets of vessels. It is usually larger in females than in males, showing that it does not influence the vocal apparatus; it is found in all mammals, birds, and reptiles, probably in the batrachians, and perhaps also in fishes. The organ may be inflamed, with suppuration, and variously enlarged, as in the disease called bronchocoele. (See GOITRE.)

TIAHUANICO, the name of ruins situated on the shores of Lake Titicaca, Bolivia, in lat. $16^{\circ} 42' S.$, long. $68^{\circ} 42' W.$ They hold the same relation to the aboriginal monuments of South America that those of Palenque sustain to the ancient remains of Central and North America; and they indicate a different and higher order of art than was found to exist, at the time of the Spanish conquest, in any other part of that continent. The ancient Peruvians had but the vaguest traditions concerning them, believing that the structures of which they are the remains were raised in remote ages, by giants, in a single night. The chroniclers of the conquest have described them, and their accounts do not differ materially from those of modern travellers. They are nevertheless in a state of extreme dilapidation, with all the evidences of remote antiquity. Some of the structures seem to have been built on a pyramidal plan, and to have covered several acres; but the most remarkable features still remaining are monolithic doorways, pillars, and statues of stone, elaborately sculptured in a style wholly different from any other remains of art yet found in America. One of these doorways is 10 ft. high, 13 ft. broad, with an opening 6 ft. 4 in. by 8 ft. 2 in., the whole cut from a single stone. Its E. front has a cornice, in the centre of which is a human figure of strange form, crowned with rays, interspersed with serpents with crested heads. On each side of this figure are three rows of square compartments, filled with human and other figures, of apparently symbolic design. The statues are broken, so that it is difficult to state their original dimensions; but these may be inferred from the size of the head of one, which is 4 feet in length and of proportionate width. The whole neighborhood is strewn with vast blocks of stone elaborately wrought, some of which, excavated in 1846, measure 8 ft. in length by 18 ft. in width, and 6 ft. in thickness. On some of the islands of Lake Titicaca are other monuments, of great extent, but of true Peruvian type, apparently the remains of

temples destroyed on the arrival of the Spaniards. Those of the island of Coati, however, have many features in common with the ruins of Tiahuanico, and probably belong to the same epoch, and are to be ascribed to the same unknown and mysterious people who preceded the Peruvians as the Tulinhuacas or Toltecs did the Aztecs.—Tiahuanico is 12,930 feet above the sea, and the country around it is cold and relatively barren. The ruins stand on an eminence, which, from the water marks around it, seems to have been formerly an island in Lake Titicaca; but the level of the lake is now 185 feet lower, and its shores 13 miles distant. This fact, in conjunction with others, warrants the belief that these remains antedate any others known in America.

TIARA (Gr.), a species of high hat anciently worn by many eastern nations. Those of kings, priests, and persons of rank terminated in the upper portion in a sort of crown, whence in modern times the term tiara has been applied to the triple crown worn by the popes, and which in turn bears a striking resemblance to the crowns worn by the Assyrian kings, as represented on the slabs discovered at Nineveh.

TIARELLA, the name of a genus of hardy herbaceous plants of the saxifrage family, commonly called bishop's cap. One of the earliest spring flowers in our woods and on the northern slopes of the Alleghanies is the *tiarella cordifolia*, with a creeping root sending out runners, and clothed with persistent, hairy, heart-shaped, lobed and toothed leaves on long hairy petioles. The flowers grow upon a long simple raceme, are entirely white, with lanceolate-acute petals, and the stamens with yellow anthers. Two or three other species are found wild in the extreme north-west. The tiarella is easily propagated in sandy peat, and is much esteemed abroad.

TIBALDI, PELLEGRINO, otherwise called Pellegrino Pellegrini, an Italian painter and architect, born in Bologna in 1527, died in Milan about 1598. At 20 years of age he visited Rome, where he studied carefully the works of Michel Angelo, but met with little success as painter or architect, both of which professions he followed, until he was employed by Cardinal Poggio to decorate his palace in Bologna. In 1586 he was invited by Philip II. to Spain, and during a residence there of 9 years executed elaborate series of frescoes in the lower cloister of the Escorial and on the ceiling of the library, beside many easel pictures, now in the churches of Madrid and elsewhere. His most successful architectural designs were the modern façade attached to the cathedral of Milan, and the Casa Professa, or house of the Jesuits, in Genoa. He endeavored to give softness to the severe forms of Michel Angelo, and was called by the Carracci the *Michelagnolo riformato*.

TIBBOOS. See TUAHOCKS.

TIBER (It. *Tevere*; anc. *Tiberis*), a river of Italy, rising at the foot of Monte delle Balze, in the Tuscan Apennines, and thence pursuing

general southerly course to Fiano, where it turns S. W., and passing through the city of Rome discharges its waters into the Mediterranean at Ostia by two mouths, which enclose the insula Sacra of the ancients. Its length is about 200 m., and its width at Rome and below from 300 to 500 feet. Its principal affluents are the Chiasco, the Velino, the Nera, and the Tevere on the left, and the Arnolfo, the Tevere, the Paglia, the Vizza, and the Ricano on the right side. It is navigable for vessels of 130 to 200 tons to Rome, 18 m. from its mouth, and for boats to the confluence of the Nera, about 10 m. Rome and Perugia are the principal cities in its basin. From Perugia, above its confluence with the Chiasco, to its debouchure, its waters have a yellowish tinge, the result of the yellow clay through which it passes; and this color is perceptible at sea for some miles from its mouth. In the upper part of its course, between Todi and the Passo del Forello, it is obstructed by rapids and passes for some miles through a narrow gorge. It is the largest and most important river of peninsular Italy.

TIBERIAS. See GENNESEARETH.

TIBERIUS, the third emperor of Rome, born Nov. 16, 42 B. C., died March 16, A. D. 37. His full name was Tiberius Claudius Nero Caesar. He was the eldest son of Claudius Tiberius Nero and Livia Drusilla, and was born amid the troubles of the civil war, in the dangers of which both his parents shared. His father had embraced the cause of Antony during the Perusian war, was forced to flee from Naples with his wife and infant son, and wandered through Sicily and Achaia until the reconciliation of Antony and Octavius in 42 B. C. enabled him to return to Rome; and in 38 he divorced his wife in order that she might be married to Augustus. In 33 the father of the young Tiberius died, and his funeral oration was pronounced before the rostra by his son, then only 9 years old. The latter was educated by the emperor with princely care, and early showed evidence of great talents; but the attention he paid to his studies and his natural reserve, the inheritance of the Claudian family, led his companions to give him the title of the "old man." In 29 he accompanied Augustus on his triumphal entry into Rome, and subsequently married Vipsania Agrippina, by whom he had a child named Drusus; but in 11 he was compelled by the policy of Augustus to divorce her, much against his will, and marry the beautiful but dissolute Julia, the daughter of the emperor. In spite of her licentiousness he seems to have lived peaceably with her for 10 years, and had by her one child which did not live; and after that event the feelings of dislike between them gradually increased until they led to a virtual separation. Tiberius during the lifetime of Augustus took an active interest in military affairs. As military tribune he made his first campaign in the Cantabrian war. In 20 he went to Asia Minor, restored Tigranes to the throne of Armenia, and compelled the

Parthians to give up the eagles taken from Crassus; in 15 he and his brother Drusus carried on a war against the Alpine nations of Rhaetia, and the exploits of the two were celebrated by Horace. In 13 Tiberius became consul with P. Quintilius Varus; in 11 conducted the war against the revolted Dalmatians and the Pannonians; and in 9, when Drusus was fatally injured in Germany, he hastened from Pavia to the place where his brother was dying, and after his death conveyed the body to Rome, walking all the way before it on foot, and on arriving in that city pronounced over it a funeral oration in the forum. He returned to Germany, gained several victories, and crossed the Rhine, but in 7 B. C. he went back to Rome, celebrated his second triumph, and was made consul a second time. The following year he obtained tribunitian power for 5 years, an unusual distinction, but suddenly formed the resolution of retiring to Rhodes. The reason for this movement is not certainly known. According to Tacitus, it was to get away from the licentiousness of his wife; but other authorities state that the step was taken on account of the growing jealousy between himself and the grandsons of Augustus. At Rhodes he resided 8 years, living in a very simple style, on terms of friendly intercourse with Greek philosophers and poets, and studying among other things astrology. While absent his wife was banished (2 B. C.) to the island of Pandataria, and at the expiration of his tribunitian power Tiberius asked leave to return to Rome; but Augustus, who in the first place had been unwilling that he should depart, was now as unwilling that he should come back, and it was not until A. D. 2 that the required permission was granted. Even this was not given except with the consent of Caius Caesar, the grandson and heir of the emperor, and with the pledge that he would take no part in public affairs. The death of the two grandsons of Augustus left Tiberius the succession to the throne, and in A. D. 4 he was adopted by Augustus. From this time to the death of the reigning emperor he was constantly employed in military operations, in which he manifested signal ability. He conquered all Illyricum, gained great victories over the Germans and the Dalmatians, and in A. D. 12 celebrated his fourth triumph. His military successes were all important, as the loss of Varus and his legions in Germany had placed the empire in danger. In A. D. 14 he started for Illyricum to conduct the war in that quarter, when he was recalled by the death of Augustus to ascend the throne. One of the first acts of his reign was to put to death Agrippa, the only surviving grandson of Augustus, alleging that the execution was in accordance with the wishes of the late emperor. Hitherto he had conducted himself in a manner to inspire respect, if not affection, and his military reputation was deservedly very high. The first years of his reign were marked by prudence and moderation. He re-

jected all flattery from the senate, placed in office the most worthy persons, and made efforts to relieve the scarcity of bread constantly recurring in Rome. Meanwhile the legions in Pannonia upon the death of Augustus were roused into a mutiny, which was only quelled by the energy of Drusus, the emperor's son, and the terror inspired by an opportune eclipse of the sun. The armies on the Rhine under Germanicus, the nephew of Tiberius, manifested also no friendly feeling for the new monarch, but the fidelity of their leader prevented any serious consequences. The first year of his reign was likewise marked by the death of his wife Julia, whom since his accession he had deprived of the allowance granted her by her father. Under the influence of Sejanus, who had become his favorite, the natural severity of his temper began soon to degenerate into cruelty. The election of magistrates was taken from the popular assembly and transferred to the senate, which sat simply to register the decrees of the emperor. The charges of *laesa majestas*, by which all persons suspected of impugning by word or deed the majesty of the emperor were tried, were prosecuted with great severity. The secret police of *delatores*, or spies, was rapidly organized, and by their infernal machinations exposed the life, the fortune, and the honor of every Roman citizen to hourly danger. After the death of Germanicus (see GERMANICUS) the emperor surrendered himself more and more to the influence of Sejanus. By his advice the prætorian cohorts, stationed hitherto in various parts of the city, were assembled in one camp, situated in the vicinity of Rome. At the same time the power of the empire was thoroughly maintained in the provinces, and two revolts in A. D. 21, one on the Moselle headed by Julius Florus, and the other among the Ædui headed by Julius Sacrovir, were put down and their leaders forced to slay themselves to escape from the imperial troops. In 23 Sejanus caused the death of Drusus by poison. Whether Tiberius felt any sorrow or not, he certainly manifested none; and when the people of Troas sent him a message of condolence, he sneeringly sent back an answer of condolence on the death of their fellow citizen Hector. In 26 the emperor left Rome, never to enter again within its walls. His retirement was dictated probably in part by the machinations of Sejanus, who wished to raise himself to the supreme power, but still more by his hatred of a city where his love of privacy was subject to be constantly disturbed. He first went to Campania, and there issued an edict commanding the people not to molest his retirement; but he gained a fuller security from intrusion the following year by going to Capreae. The early part of his reign had been marked by a strict regard for external decency, and a stringent law had been passed against courtesans; but his last years were spent in the most infamous pleasures. The island of Capreae became the

haunt of a most disgusting debauchery, especially after the death of Livia Drusilla in 29, who had always exercised much influence over her son. Although he paid her respect and obedience, he did not pretend to an affection which he did not feel. He had left Rome partly to be out of her way, and in her last illness he refused to visit her. Henceforth Sejanus had the full control of affairs of state, and bent every thing to the accomplishment of his own ambitious designs. The employment of *delatores* gave abundant means of getting rid of obnoxious individuals on false charges. Tiberius, who had been suspecting for some time the plots of his minister, managed to get rid of Sejanus in 31, and the favorite and all his family were destroyed. In the mean time conscience was doing its work, and the emperor became, in the words of Pliny, "the most wretched of men." In the remarkable letter sent to the senate, which Tacitus has preserved, he begins with a frank avowal of his misery. "What to write to you," he says, "or how to write, I know not; and what not to write at this time, may all the gods and goddesses torment me more than I daily feel that I am suffering, if I do know." About this time he left his retreat in Capreae, went once more to Campania, and occasionally came as near Rome as his gardens in the Vatican. But his privacy was never disturbed; soldiers were placed so as to prevent any one from coming near him. Though formerly remarkable for beauty and majesty of person, dissipation had covered his face with ugly blotches, and his body was bent nearly double. At Astura he was attacked by sickness, and reached Misenum to die in the villa of Lucullus. According to Tacitus, it was left to fate to determine his successor. On March 16 he had a fainting fit, and being thought dead, Caius Calpurnia was saluted as his successor; but the emperor suddenly recovering, a quantity of clothes was thrown over him and he was left alone. There is another account of his death. The people hailed the event with delight, and the cry of "Tiberius to the Tiber" was heard constantly in the streets of Rome. He however had a public burial, but did not like Augustus receive divine honors. The chief authorities for his life are Suetonius, Dion Cassius, and above all Tacitus. He wrote a commentary of his own life, Greek poems, an ode on the death of L. Cæsar, and several epistles and orations, either to the senate or on occasion of funerals; and were he to be judged by his words and not his deeds, he would doubtless be deemed one of the best and wisest of the Roman emperors.

TIBET. See THIBET.

TIBULLUS, ALBIUS, a Roman elegiac poet, who flourished during the reign of Augustus. He was of an equestrian family, and spent the greater portion of his life on his ancestral estate at Pedum between Praeneste and Tiber. Though naturally averse to a military life, he went to Aquitania in 81 B. C. with his patron

Messala, who had been sent thither to quell an insurrection; and when Messala had pacified that part of Gaul and set out to take command in the East, Tibullus accompanied him, but falling sick returned to Rome. With this his military life ended. Four books of elegies are attributed to him, but the third book is considered spurious. Tibullus was a warm friend of Horace, and two poems addressed to him by the latter are extant. He died while still young. The first edition of his works was printed along with Catullus, Propertius, and the *Silvæ* of Statius at Venice in 1479. Of the late editions, two of the best are those of O. Lachmann (Berlin, 1829) and Dissen (Göttingen, 1885). They have been translated into English verse by Dr. Grainger (1752), and a prose translation forms a volume of Bohn's "Classical Library" (London, 1854).

TIBUR. See TIVOLI.

TIO DOULOUREUX. See NEURALGIA.

TICINO, or TESSIN, a S. canton of Switzerland, bounded by Uri, Grisons, Lombardy, Piedmont, and Valais; area, 1,082 sq. m.; pop. in 1860, 181,896, all but 118 Roman Catholics. The surface is mountainous, but the N. part is more elevated than the S., that frontier being formed by several of the most lofty summits of the Alps, including the Splügen, Mt. St. Gothard, and Mt. St. Bernard, and a considerable portion of it belongs to the glacier region. The face of the country has a general slope toward the S., and lofty mountain ridges traverse it in that and a S. E. direction, and send numerous offsets to both sides, the whole forming many valleys, each traversed by a mountain stream. With the exception of a small part of the south, the whole drainage belongs to the basin of the Po. The principal river is the Ticino, which, rising in Mt. St. Gothard and receiving numerous tributaries, flows through Lago Maggiore, a small portion of which is within the boundary of the canton, to the Po near Pavia. There are several other lakes, the most important of which are Lugano, Muzzano, and Origlio. The elevated surface of the N. part of the canton is not well suited for agriculture, but in the S. the lower slopes are covered with forests of chestnuts, and the valleys with vineyards, corn fields, and plantations of figs, almonds, oranges, citrons, mulberries, and pomegranates. In the elevated part large numbers of cattle are reared, and the inhabitants are chiefly occupied in preparing dairy produce. Game is abundant in the forests, and the streams and lakes are well stocked with fish. The manufactures are confined to a few articles for domestic use. A trifling transit trade is carried on through this canton between Switzerland and Italy, and small quantities of silk, fruits, cheese, skins, marble, crystals, and timber are exported. The inhabitants belong to the Italian race, and speak that language. Large numbers of the men annually migrate to other countries in search of employment, and leave the care of their cattle and farms to the women

in their absence.—Ticino was conquered from Italy by the Swiss in 1512, and, under the name of the Italian bailiwicks, governed by deputies until 1815, when it was admitted as a member of the Swiss confederation. The government is vested in a council chosen by all citizens who have attained the age of 25 years, and possess property either in fee to the value of \$40 or a life estate of \$60; the council meets alternately at Lugano, Locarno, and Bellinzona. The canton pays \$5,500 annually as its share of the support of the confederate government, and furnishes a contingent of 1,804 men.

TICK. See EPIZOA, vol. vii. p. 253.

TICKELL, THOMAS, an English poet, born in Bridekirk, Cumberland, in 1686, died in Bath, April 28, 1740. He was educated at Queen's college, Oxford, and in 1710 was chosen fellow, and by a royal dispensation was allowed to hold his fellowship without taking orders. Some praises of Addison's opera of "Rosamond" gained him the favor of that author, and from that time the most intimate friendship existed between them. During the negotiations for peace with France, Tickell published a poem entitled "The Prospect of Peace," which rapidly went through several editions on account of the praise bestowed upon it by the "Spectator." On the arrival of King George I. he wrote "The Royal Progress," printed in the "Spectator." But his greatest production was his translation of the first book of the Iliad, which was brought out in opposition to that of Pope. Addison declared that this now forgotten version was the best ever made, and it has been suspected that he himself was the translator. Beside some minor poems, the only remaining work from his pen is one entitled "Letter to Avignon," written during the dispute on the Hanoverian succession, and an elegy on Addison, prefixed to the edition of his works, of which Dr. Johnson expressed the extravagant opinion that it was equal for sublimity and elegance to any funeral poem in the English language. Addison had employed Tickell in public affairs, and when in 1717 he was appointed secretary of state, he made him his under secretary. In 1725 Tickell became secretary to the lords justices of Ireland, in which situation he died.

TICKNOR, GEORGE, an American author and scholar, born in Boston, Aug. 1, 1791. He was graduated at Dartmouth college in 1807, and afterward devoted three years in his native town to the study of the ancient classics, availing himself of the best aids and facilities which the educational resources of the time and place afforded. After the usual preparatory course he was admitted to the bar in 1818, but his connection with the legal profession was never any thing but nominal. For the purpose of securing a wider and more thorough cultivation than his own country at that time afforded, he embarked for Europe in 1815, and remained abroad 5 years, residing at Göttingen, Rome, Madrid, Paris, Edinburgh, and London, and

becoming acquainted with Goethe, Lord Byron, Sir Walter Scott, Mme. de Staël, Jeffrey, Rogers, Lord Holland, Roscoe, Mackintosh, Wordsworth, Southey, and other distinguished personages. Upon his return home he assumed the duties of a professorship recently founded in Harvard college of French and Spanish languages, literature, and belles-lettres, to which he had been chosen in his absence. He devoted himself to his new occupation with ardor and energy, giving an impulse to the studies of his department not merely by his excellent lectures, but by his diligent supervision of the elementary instruction in all its branches. He resigned his professorship in 1835, and went abroad a second time, accompanied by his family, and remained there 8 years. After his return he devoted himself principally to the preparation of a "History of Spanish Literature," a work which he had long meditated, and for which he had collected ample materials. It was published in New York in 1849 (8 vols. 8vo.), and at once attained the rank of a classic in the language. Its thoroughness, minute and accurate knowledge, sound judgment and unerring taste, and elegant and judicious criticism were acknowledged by the scholars of every country, and by none more heartily and unreservedly than by those of Spain itself. No other work on the same subject, in any language, could enter into comparison with it for fulness, comprehensiveness, and accuracy. It has been translated into Spanish and German. Mr. Ticknor has also edited "The Remains of Nathaniel Appleton Haven," with a memoir of his life. (See HAVEN, NATHANIEL APPLETON.) In 1825 he contributed to the "North American Review" a life of Lafayette, which was subsequently enlarged, and published in pamphlet form. Mr. Ticknor was also one of the association of writers by whom the "Monthly Anthology" was conducted. He is at present (March, 1862) occupied with a biography of his friend W. H. Prescott, and the preparation of a new and revised edition of his "History of Spanish Literature." For some years past Mr. Ticknor has been a trustee of the public library of the city of Boston, which owes much of its success to his judicious labors in its behalf.

TICONDEROGA, a post village and township of Essex co., N. Y., enclosing the outlet of Lake George, 95 m. N. by E. from Albany; pop. in 1855, 2,125. The portion of the town lying between Lakes George and Champlain is a lofty promontory, the terminus of a mountain ridge; Mt. Defiance at the extremity of the promontory is 750 feet above the surface of Lake Champlain. The outlet of Lake George, 4 m. in length, has a fall in $1\frac{1}{4}$ m. of 150 feet; and as the quantity of water never apparently varies, and is remarkably pure, it forms a very valuable water power. There is a vein of graphite of excellent quality in the town, and about 80 tons of black lead are produced annually. Large quantities of lumber are manufactured here, and there are extensive

tanneries.—The town is particularly remarkable for the prominent place its fortifications have held in American history. Early in 1755 the French, who had already occupied and fortified Crown Point, and caused a careful survey of Lake Champlain to be made, advanced to Ticonderoga and commenced a fortification there, which entirely commanded the passage of the lake. This fort they named Carillon (chime of bells), in allusion to the music of the waterfalls near it. It was afterward known as Fort Ticonderoga. Sir William Johnson was the commander of an English and colonial army the same year intended for the reduction of this fortress and Crown Point; but learning that the French had reinforced it largely, he contented himself with fortifying Fort William Henry at the S. end of the lake. In 1757 Montcalm assembled a force of 9,000 men at Fort Carillon, and ascending Lake George attacked and reduced Fort William Henry, Aug. 8. In the summer of 1758 Gen. Abercrombie took the command of an expedition for the reduction of Fort Carillon, crossed Lake George with 15,000 men, and on July 8 attempted to take the fort by storm, but was repulsed with a loss of 2,000 men. In 1759 Gen. Amherst at the head of 12,000 men proceeded to invest Ticonderoga, and the French, not having a sufficient force to hold it, dismantled and abandoned it, July 30, and soon after Crown Point was also abandoned. The English government then enlarged and strengthened the two fortresses at an expense of \$10,000,000. The fort and field works of Ticonderoga extended over an area of several miles. After the cession of Canada in 1763, the fort was allowed to fall into partial decay, and was held by a small force. Upon the receipt of the news of the battle of Lexington, Col. Ethan Allen surprised the fort, May 10, 1775, and captured the garrison of 50 men and the artillery and munitions of war in the fort. (See ALLEN, ETHAN.) In 1776, after an engagement between the British and Americans, the latter were compelled to take refuge under the guns of Fort Ticonderoga. On June 30, 1777, Burgoyne invested the fort, and on July 4 erected a battery on Sugar Loaf hill (now Mt. Defiance), which completely commanded it and compelled the garrison to evacuate it the next night, sending their stores and munitions to Skenesborough (now Whitehall), and escaping themselves into Vermont. In September of the same year Gen. Lincoln made an attack upon the works, took Mts. Hope and Defiance, released 100 American prisoners, and took 298 of the enemy, an armed sloop, several gun boats, and more than 200 bateaux, but did not capture the fort. After the surrender of Burgoyne the fort was dismantled, and the garrison retreated down Lake Champlain; a portion of them were captured by Capt. Ebenezer Allen. In 1780 Gen. Haldeman with a company of British soldiers advanced to Ticonderoga and occupied it for some time; and from this point Major Carle-

on made a diversion against Forts Anne and George, in favor of Sir John Johnson. After the war the fort was suffered to fall into ruins, the extent of which is the only existing indication of its old importance.

TIDES, the alternate rising and falling of the waters of the ocean, which is to be observed on all its coasts and estuaries. The rising is designated as the flood, and the highest elevation as high water; the falling is called the ebb, and the lowest depression low water. The duration of high and low water without apparent change of level is known as the stand, and the cessation of the ebb and flood streams or tidal currents is called slack water. If we suppose an observer stationed on the shores of a bay communicating with the open sea, as on Governor's island in New York bay, he will remark certain regular changes in the state of the water. The first and most important of these is that the surface of the water rises and falls regularly twice in every day. A closer attention will show that the tides of each day occur somewhat later than those of the preceding day, the average retardation from day to day being about 50 minutes. In a short time he will find that the times of occurrence of high water bear a very close relation to the appearance of the moon in certain positions. Thus at New York high water occurs when the moon is about E. S. E.; at Newcastle, on Delaware river, when the moon is nearly S.; at Baltimore when it is rising or setting. These are rude statements, but they are sufficiently accurate for many purposes, and they show at once the close connection between the time of high water and the time of the moon's passage over the meridian. In fact, so completely is this recognized, that, in order to give the time of high water upon any day, it is usually thought sufficient to state the time of high water on the days of new moon and full moon (or "full and change") when the moon passes the meridian at 12 o'clock nearly. This time is called the establishment of the port. Then to find roughly the time of high water on any other day, it is only necessary to add the establishment to the time of the moon's meridian passage that day. There will also be another high water on the same day, preceding or following that so found by 12h. 25m. nearly. On closer examination it will be found that the interval between the time of the moon's passage over the meridian and the time of high water varies sensibly with the moon's age. At new moon, full moon, first quarter, and third quarter (or there on the day following each of these phases), the interval between the time of the moon's passage and the time of high water is nearly the same; but from new moon to first quarter, and from full moon to third quarter, the high water occurs earlier than would be inferred by using that same interval; and from first quarter to full moon, and from third quarter to new moon, it occurs later than the same interval would give it. If the observer exam-

ines the height of the water, he will find that the height at high water and the depression at low water are not always the same. On the days following new moon and full moon, high water is higher and low water lower than at any other time; these are called spring tides. On the days following the first and third quarters, high water is lower and low water higher than at any other time; these are called neap tides. Thus at New York the rise and fall (that is, the difference in elevation between high water and low water) is about $5\frac{1}{2}$ feet at spring tides, and $3\frac{1}{2}$ feet at neap tides. At Boston this variation is from $11\frac{1}{2}$ to $8\frac{1}{2}$ feet. He will further notice that there is a sensible difference in height between the two successive high waters or low waters, one occurring before noon, the other after noon, and that these differences are most perceptible when the moon is at her greatest declination N. or S., and that they disappear when she is near the equator. There are other variations of height depending on other circumstances; but they require, for the most part, very numerous observations to establish the fact of their existence, and to give a measure of their amount. — Upon examining the circumstances of a single tide, the following facts will attract notice: The interval from high water to low water is greater than that from low water to high water; the difference between these intervals is sensibly greater at spring tides than at neap tides. The tidal current in the bay runs upward for some time after high water, and after changing its direction continues to run downward for some time after low water, when it again changes its direction, and runs upward. If we further examine the state of the tide in different parts of the same river, or in a bay of great length as compared with its breadth, as for instance Chesapeake bay, we shall find that near the mouth there is very little difference between the interval from high to low water and that from low to high water; also that the current runs up the channel for a long time (sometimes approaching to 8 hours) after high water, and runs down the channel for as long a time after low water. In going up the bay we find that the high water occurs later and later, but yet that the velocity with which the high water travels is so great as entirely to preclude the idea of explaining the tide by supposing the same mass of water to have been moved all the way up the bay. Thus, high water is 18 hours in travelling from Cape Henry to the head of Chesapeake bay, a distance of 190 m., moving with an average velocity of 15 m. per hour, while the greatest observed current is less than one mile per hour. High water takes place simultaneously near the head and the mouth of the bay, while it is low water at the same time near the middle. The interval from low water to high water diminishes as we go up the bay, as also the difference between the stand and slack water. At the entrance of the bay the ebb current begins 8

hours after the high water stand; in the vicinity of Annapolis it is but one hour, and at the head of the bay there is only half an hour between the high water stand and the commencement of the ebb current.—The phenomena which we have described must necessarily have been remarked, for the most part, by all nations bordering on the ocean, and the fact that they are in some way connected with the moon could not escape their notice. Owing to the circumstance that in the Mediterranean sea, as in other seas of small extent, the tide is nearly imperceptible, the Greeks had little opportunity of observing them. Herodotus speaks of the tides in the Red sea. Plutarch says that Pytheas of Marseilles, who had observed them in Britain, ascribed them to the moon. Cæsar, in his account of the invasion of Britain, refers to the nature of spring tides as well understood in connection with the moon's age. Pliny explains the phenomena at some length, and ascribes them to the sun and moon dragging the waters along with them. Kepler in accounting for the tides had evidently been aware of the principle of gravitation, but not of the law. He says that all bodies attract each other, and that the waters of the ocean would all go to the moon were they not retained by the attraction of the earth. He then proceeds to explain their elevation under the moon and on the opposite side, because the earth is less attracted by the moon than the nearer waters, but more than the waters on the opposite side. These views, which contain the true explanation of the tides, although in an undeveloped state, were not generally accepted by his contemporaries. Galileo, to whom they were known, rejects them, and prefers another theory which it is not necessary to state here. The honor of a complete explanation of the causes of the tides was reserved to Newton, who laid hold of this class of phenomena as the most incontestable proof of universal gravitation, and showed that according to its law just such periodic fluctuations in the fluid covering of the earth must take place as are actually exhibited by the tides of the ocean.—The popular explanation of the tides as depending on the law of gravitation is sufficiently simple, although the complete mathematical investigation of the subject by which we should be enabled to predict their occurrence and magnitude for any place is encompassed with difficulties, from causes to which we shall hereafter revert. If we conceive the earth to be wholly, or in a great degree, covered with water, and subject to the attraction of the sun, the force of which is inversely as the square of the distance, it will be obvious, that while the whole earth will fall toward the sun with a velocity proportioned to the aggregate attraction upon its solid portions (which is the same as if all the matter were collected at its centre), the water nearest to the sun, being accelerated by a greater force, and being fluid, will ap-

proach the sun more rapidly than the solid core. It will thus run from all sides into a protuberance beyond the form of equilibrium of the earth's attraction and rotation, until the pressure of the elevated mass equals the difference in the attraction of the sun. Moreover, a similar protuberance will be formed on the side opposite to the sun, since the particles of water, being solicited by a less force than the solid core, will fall more slowly toward the sun, and as it were remain behind. Nor does the fact that, on the average, the earth does not lessen its distance from the sun, in the least invalidate the force of this reasoning; for the deviations from the tangential motion of the earth in its orbit are precisely those which the earth would move through if falling toward the sun unaffected by any other impulse. The same considerations hold good in regard to the attraction of the moon upon the earth and the waters surrounding it; for although we are in the habit of considering the moon as simply revolving about the earth, it must be remembered that the attraction is mutual, that both bodies describe orbits about their common centre of gravity, and that while the moon obeys the attractive force of the earth, the latter equally follows that of the former, by which it is at every instant of time drawn from the path which it would pursue if that influence did not exist, by an amount precisely equal to the fall corresponding to the moon's attractive force. As a necessary consequence of the elevation of the water in the regions nearest to and most remote from the attracting body, there must be a corresponding depression below the mean level of the sea at points distant 90° from the vertices of the protuberances, or at the sides of the earth as seen from the sun or moon. If the latter bodies maintained a constant position with respect to the earth, the effect would therefore be to produce a distortion of figure in the ocean surface (assumed to cover the whole earth) having the form of a slightly elongated ellipsoid, the two vertices of which would be, the one precisely under, the other precisely opposite to the points at which the disturbing body is vertical. This, however, is not the case; for by the rotation of the earth, and the motion of earth and moon in their orbits, the direction of the disturbing forces is constantly changing with respect to any point on the earth's surface. New points arrive at every instant under the zenith and nadir of either luminary, and thus it is that waves are produced which follow them round the globe. The highest points of these waves will remain far behind the verticals of the disturbing bodies, because the inertia and friction of the water prevent the rapid change of form required, and because, although the elevating force is greatest under the vertical, it still continues to act in the same direction for some hours after the passage of the luminary, with but little diminished force. This retardation, which would be sensible under the simple supposition of an uninter-

rupted ocean covering the earth's surface, becomes very considerable under the actual circumstances of the case.—The depth of the sea varies so much, and the form of its basin, taken as a whole, is so interrupted by the land, that it may be doubted whether, were the action of the sun and moon at once suspended, their tide waves would perform even a single revolution with any sort of regularity, and in the course of two or three would be so broken up and confused by reflection to and fro, as to destroy all vestige of a tide. Hence it follows, that the tides for the time being may be considered as almost completely commanded by the then actual positions and proximities of the sun and moon, the free oscillations of the sea in its bed being quite subordinate to the forced wave generating them. In consequence (as is always the case in forced oscillations), every periodicity in the action of the forcing cause is propagated into the oscillations, and records itself in the recorded height of the tide on every point of the coast, but at each point at a greater or less interval from the culmination of the sun or moon, according to its local position and the more or less circuitous course taken by the tide wave to reach it, and which special observation can alone determine. This interval is called the establishment of the place. The close relation which the times of high water bear to the times of the moon's passage, shows that the moon's influence in raising the tides must be much greater than the sun's. In fact, while the whole attraction of the sun upon the earth far exceeds that of the moon, yet owing to the greater proximity of the latter, the difference between its attraction at the centre of the earth and at the nearest or most remote points of its surface, which produces the tides, is about $2\frac{1}{2}$ times as great as the difference of the sun's attraction at the same points.—We will now consider the particular phases resulting from the combination of the lunar and solar tides and from the varying positions of those luminaries. There will be two complete lunar tides in every lunar day of 24h. 49m., and also two complete solar tides in every mean solar day. These are known as the semi-diurnal tides, and constitute the principal fluctuations of the sea level. When the sun and moon are in conjunction or opposition, at the time of new or full moon, the effects of both combine to produce the spring tides, when high water is higher and low water is lower than at mean tides by the amount of the solar tide. At quadratures the high water of the sun will combine with the low water of the moon to produce a less fall, and the low water of the sun with the high water of the moon to produce a less rise, than at mean tides; and we have the neap tides, the range of which is less than the mean range by the amount of the solar tide. Thus, at New York, the rise and fall at syzygies is 5.4 feet, at quadrature 3.4 feet, the former being the sum, the latter the difference of the lunar and solar tides;

whence we obtain for the effect of the moon 4.4 feet, and for that of the sun 1 foot, or a ratio of 4.4 to 1. This proportion does not prove to be the same in all parts of the world, and even varies considerably in places not far distant from each other. At Boston the heights are 11.3 and 8.5 feet respectively, giving a proportion of 7 to 1. On the Atlantic coast of the United States it averages about 5 to 1, while on the E. side of the Atlantic ocean, on the coasts of France and England, it is in many parts 8 to 1. These differences are to be ascribed to the fact that the shore and harbor tides which we observe have in every instance acquired a greater magnitude than the ocean tides, in consequence of the tide having passed over a sloping bottom, by which the solar and lunar tides, being of different depths, are altered in different degrees. A comparison of the range of spring and neap tides will not serve, therefore, as a correct measure of the relative effect of the sun and moon, and hence for a determination of the mass of the moon, unless they could be observed in mid-ocean. In the North Atlantic the highest tides are not observed immediately after the syzygies, but a day and a half or two days afterward. At New York, the high water which we observe about 8 o'clock in the evening on the days of full or change are those due to the meridian transit of the moon (and sun) on the preceding day, and the highest tide will not occur until the evening of the following day. At Boston, this delay, which is called the retard, or age of the tide, is nearly 86 hours. It is the same at Brest, and the tide wave occupies 10 hours in travelling from Brest up the English channel and Thames to London, making the age of the tide at the latter place 46 hours. This delay, which even at the Cape of Good Hope amounts to 14 hours, is still the subject of investigation, and is probably mainly due to friction. The interval between the moon's passage over the meridian of a place and the time of high water, which we have referred to as the establishment of the port, is also called the luni-tidal interval. This interval is constant for each place so far as the lunar tide wave is concerned; but as the actual high water depends upon the combination of the lunar and solar tides, it is subject to a variation which is known as the half-monthly inequality in time. On the day after the spring tides the top of the solar tide wave will be nearly an hour in advance of that of the lunar tide wave, and the two waves will combine to make high water earlier than the moon's alone would bring it; hence the luni-tidal interval is shorter. It will continue to shorten until the moon's transit is later by 8 hours than when the tide is greatest; it then increases again, passes its mean value when the moon has fallen behind 6 hours, attains its maximum when it is 9 hours later, and again decreases until at the next spring tides it reaches its mean value. The mean of all the luni-tidal intervals for half a month at a port is called

its mean or corrected establishment, to distinguish it from the vulgar establishment, which is the luni-tidal interval at full and change. The former is now generally used for finding the time of high water on any given day, and tables are constructed from observations at the principal ports for finding the correction for semi-monthly inequality due to the moon's age. Thus for New York the corrected establishment or mean luni-tidal interval is 8h. 18m., and its least and greatest values are 7h. 52m. and 8h. 35m. On the Atlantic coast of the United States the range of this inequality is about $\frac{1}{2}$ of an hour; on the coasts of France and Great Britain it often exceeds $1\frac{1}{2}$ hours. This difference of the half-monthly inequality in time at different places is analogous to the variation in the proportion of spring and neap tides above noticed, and is due to the same causes, the nature of which we have indicated, but which are not yet fully understood.—The next variation of the tides to be considered is that dependent on the moon's declination. Were she constantly in the plane of the equator, the highest points of the tide waves would also be in that plane, and would consequently produce a series of equal tides at any place either N. or S. of the equator. But it is evident that when she ascends to the north, the vertex of the tide wave will tend to follow her, giving the highest point of one tide in the northern, and the highest point of the opposite tide in the southern hemisphere. Consequently, when the moon has a northern declination, the tide at any place in the northern hemisphere caused by her upper transit will be higher than that caused by the lower transit. This variation in the heights has a period of one lunar day, and is called the diurnal inequality; it reaches its maximum when the moon is at its greatest northern or southern declination, and disappears when it is on the equator, and consequently has a half-monthly period. The variations of height from this cause produce a corresponding inequality in the times of high water. The sun's declination affects the tides in a similar manner, but the amount of the disturbance is very small, and its period extends over half a year. In long series of observations its effect is nevertheless well marked, both in height and time. The diurnal inequality depending on the moon's declination is on the other hand quite sensible, and in many places constitutes a prominent or even the chief feature of the tides, as on the Pacific coast of North America and in the gulf of Mexico, to the peculiarities of which we shall recur hereafter. If the tides arrive at the same place by two different channels, and one of them is retarded behind the other by 6 hours, in consequence of travelling a longer route or in shallower water, the semi-diurnal tides will be destroyed by an interference of the waves, that is, by the high water of one being superimposed on the low water of the other; the diurnal inequality, however, will not be destroyed, but

merely modified in height and time, leaving a single tide in the lunar day outstanding, which is always very small in amount. A further cause of variation in the height of the tides is the variation of the distances of the sun and moon, by reason of the ellipticity of their orbits. The efficacy of a heavenly body in raising tides is shown by theory to be inversely proportional to the cube of the distance. Hence the efficacy of the sun will fluctuate between the extremes 19 and 21, taking 20 for its mean value, and that of the moon between 48 and 59. Taking into account this cause of difference, the highest spring tide will be to the lowest neap as $59+21$ to $48-19$, or as 80 to 24, or 10 to 3; leaving out of consideration the local circumstances of access and depth, which, as we have stated, modify those proportions in a marked degree.—The motion of the water in the tide wave is totally unlike that in an ordinary surface wave, such as the wind produces. When a narrow wave of the latter kind, or a succession of such waves of equal breadths and heights, is formed in deep water, a light floating body, as a cork, revolves either in a vertical circle or an ellipse not very different from one, having the longer axis vertical. But in the tide wave the movement of each particle may be regarded as performed in an excessively elongated ellipse, the shorter axis of which is vertical. The breadth of the tide wave from crest to crest, supposing all the earth covered, would be half the earth's circumference, or 12,500 miles, in comparison with which the depth of the sea is insignificant; and the slightest consideration suffices to show that, as all the water which goes to form the elevated portion must be brought from that depressed, this can only take place by a lateral approach of the vertical sections of the sea when the water is rising, and their recess from each other when falling—i. e., over a quadrant of the globe in either case, which is only another way of expressing an alternating backward and forward horizontal current at any given place—with this peculiarity, that these currents (the flow and ebb current) run most rapidly at the moments of high and low water; the instants of most rapid rise and fall being those of slack water or no current one way or the other. In fact it is obvious that the surface must be rising most rapidly when the water is setting in equally both ways to, and sinking most rapidly when setting out equally both ways from the place; in neither of which cases can there be any current at the place. The tide wave differs also from a wind wave in another very remarkable point. It affects the whole depth of the ocean equally, from the bottom to the surface, while the wind waves, even in the most violent storms, agitate it to a very trifling depth; for the force which acts to produce the former is exerted equally in every portion of the vertical extent of the water, while those producing the latter are strictly confined to the surface. A tide wave of 4 feet in total height (between

high and low water), which is that of the tide at the atolls of the Indian ocean, advancing over a sea 30,000 feet deep, implies in each particle an alternate advance and recess of 2,800 feet in its total extent; but this movement, being spread over 6 hours either way, is nowhere very rapid. Where a bay or indentation of the coast presents its opening favorably to the tide wave, and decreases in width from the entrance toward its head, the tides rise higher and higher from the mouth upward. This is due to the concentration of the wave by the approach of the shores, and to the gradual shoaling of the bottom by which a portion of the horizontal motion is transferred into vertical motion, the velocity of the wave being at the same time retarded. This effect is strikingly illustrated by a generalization of the heights of the tides on the Atlantic coast of the United States, developed from the tidal observations made in connection with the United States coast survey. That coast presents in its general outline three large bays: the great southern, from Cape Florida to Cape Hatteras; the great middle, from Cape Hatteras to Siasconset, Nantucket; and the great eastern, from Siasconset to Cape Sable. Referring to the tide table given below, we find at Cape Florida a mean height of 1.5 feet, and as we follow the coast to the northward a gradually increasing height, reaching 7 feet at Savannah entrance, then decreasing again, with an exception easily explained, to Cape Hatteras, where it is 2 feet. In the middle bay, following the stations on the coast, and omitting those on the bays and sounds, we have a less regular increase to 4.8 feet at Sandy Hook, and a decrease to 2.7 feet at Menemahs bight on Nantucket island. The configuration of the eastern bay is less regular, and the correspondence of heights requires closer examination. The recess of Massachusetts bay is well marked by the increase in height, reaching 10 feet at Boston and Plymouth; but the most striking effect of the convergence of shores and shoaling is exhibited in the bay of Fundy. On a line across its mouth, at the Kennebec river as at Cape Sable, the mean height of tide is 8 feet, while at St. John's, N. B., it rises 19 feet, and at Sackville in Cumberland basin, at the head of the bay, to 86 feet, attaining to 50 feet and more at spring tides. When the wave leaves the open sea, its front slope and its rear slope are equal in length and similar in form. But as it advances into a narrow channel, bay, or river, its front slope becomes short and steep, and its rear slope becomes long and gentle. Hence arise the circumstances noticed in the early part of this article, and illustrated by reference to the Chesapeake bay. At the station near the sea the time occupied by the rise is equal to that occupied by the descent; but at a station more removed from the sea the rise occupies a shorter time than the descent. When the tide is very large compared with the depth of water, this inequality becomes very great;

thus in the Severn river, at Newnham, above Bristol (England), the whole rise of 18 feet takes place in $1\frac{1}{2}$ hours, while the fall occupies 10 hours. As the wave advances over a shoaling bottom, a portion of the horizontal motion is transformed into vertical motion, by which the height of the wave is increased, the most rapid current approaches the greatest rise, and the interval between the stand and slack water is diminished. This exaggeration of the height and current is particularly remarkable whenever the front of the advancing tide wave stretches across the mouth of an estuary with contracting borders, and extensive flats bordering the channel near low water level; then it produces a bore, or sudden and violent wave of great height, which rushes forward with such impetuosity as to sweep every thing before it. Such is the case at the head of the bay of Fundy; likewise in the Hoogly river, in the bay of Bengal; in the Dordogne, where it empties into the Garonne, on the coast of France; and in the Severn river, where at spring tides a bore of 9 feet in height rushes up stream. In the river Amazon, at the equinoxes (when the equatorial tide is at its maximum), during 3 consecutive days bores of 12 or 15 feet high rush up the river with each high water; so that along the course of the stream, up which for 200 m. from its mouth no fewer than 8 tide waves are simultaneously advancing, as many as 5 bores are sometimes at once in progress. It is easily seen that in seas of small extent, which have little or no communication with the ocean, as the Mediterranean, Black, and Caspian seas, and the North American lakes, the tides must be insensible, as the attraction of the moon is at all times very nearly the same for all parts of them. Near the E. end of the Mediterranean, as at Malaga, a small tide is observable, being propagated from the Atlantic ocean through the straits of Gibraltar. Tides are also observable at Venice, but the observations have not been discussed so as to determine whether they arise from a small tide wave proper to the Mediterranean, magnified by travelling up the Adriatic sea, although insensible at its mouth, or whether they are variations due to the winds. Fluctuations of the sea level resembling those of the tides, and causing irregularities in the latter, are often produced by the winds, which in many places have a certain periodicity in their direction and force, as the land and sea breezes in the tropics. They come under consideration here only as complicating the study of the tidal phenomena.—We have now shown in a general way, as far as can well be done without the use of mathematical forms of reasoning, the nature of the forces which produce the phenomena described at the outset, and their mode of action. The existing theories, while they suffice for the explanation of the observed facts, are inadequate, as we have stated, to the prediction of the phenomena at places where they have not been observed. This arises not from any defect in the principles

upon which the theory is based, but from the difficulty of investigating mathematically the motion of fluids, under all the various circumstances in which the waters of the sea and of rivers are found, and from our ignorance of the configuration of the bottom of the sea. The equatorial sea being broken up into three great basins, and open water existing only to the southward of the three great continents, the tides are complicated in a singular way. In each of these basins the equatorial tide has to take a fresh start from the eastern side with every fresh upper and lower transit of the moon and sun, and is destroyed or confused by reflection on the western coast before the creation of a new wave; while in the open part of the southern ocean the tide wave circulates unimpeded, and spreads into the three oceans up which it runs as a free wave, from S. E. to N. W., overtaking its progress and compounding with the partial equatorial tides or forced waves proper to either ocean. On approaching the shore, the waves are elevated and retarded by the slope of the bottom, and deflected or crowded together according to the varied configurations of the coasts. It is owing to these complications, together with our ignorance of the laws of friction among the particles of water, and between the water and the bottom, that our theories fail to inform us of the magnitude and time of the tides at any given place. But they determine the periodicity of their phases, and the relative part which each disturbing force bears to the whole, by which we are enabled, by the analysis of a sufficient series of exact observations at any place, to predict the phases of the tides at the same place for any future time, the knowledge of which is of immense importance to navigation. It is only since the beginning of the present century that the science of the tides has made any considerable progress in this direction. The theoretical investigations of Laplace, in the *Mécanique céleste*, and his discussions of the tidal observations at Brest, opened the way. Mr. Lubbock and Prof. Whewell contributed largely by the elaborate discussions of large collections of tidal observations, published in the "Philosophical Transactions" of the royal society; and Prof. Airy, in his admirable essay on "Tides and Waves," in the "Encyclopædia Metropolitana," has greatly extended our theoretical conceptions of the subject. —The tides on the coasts of the United States have been specially investigated by Prof. Bache, superintendent of the American coast survey. In connection with that work he organized an extensive system of exact tidal observations, for the purpose of ascertaining the complicated laws which govern the tides of the seas that wash our shores. It will be readily understood that in order to separate the effects of the different causes which modify the phenomena, it is not sufficient to observe merely the heights and times of high and low water, but that a continuous record of the tides is neces-

sary, as the inequalities are constantly shifting their place and magnitude. For this purpose a self-registering tide gauge is used, by which a continuous curve representing the successive changes in the height of water is traced on paper moved by clockwork, by a pencil acted on by the rising and falling of a float in a vertical box, to which the tide has free access. The time scale is such that every hour is represented by one inch, and is pricked into the paper by points on the cylinder which moves the paper forward. The scale of heights is so adapted to the range of the tide at the place of observation, that the extreme range of the curve will not exceed the width of the sheet, 13 inches. A continuous sheet, sufficient for the record of a whole month, is put on the tide gauge at one time. A complete description of this instrument will be found in the coast survey report for 1858. Prof. Bache has given in his annual reports on the progress of the coast survey, from 1851 forward, a series of papers on the tides, detailing the processes of discussion, and giving the results as they were from time to time developed. The apparent anomalies in the tides in the gulf of Mexico, exhibiting at some places only one tide in 24 hours; the large inequalities in the tides on the Pacific coast; the general progress of the tide wave along our coasts and in the bays and rivers; the influence of the winds in particular localities; and the action of tidal currents on the bars and channels of our harbors, are discussed there. These labors, which are still in progress, have resulted already in tide tables for the use of navigators, by which any one is enabled, with the aid of the moon's place from the "Nautical Almanac," to find the stage of the tide at the places named in the table for any given time. Below is an extract from these tables, giving the mean luni-tidal interval, and the rise and fall, or range at spring and neap tides. The full tables give, beside, the difference between greatest and least interval, the mean rise and fall, and the duration of flood, ebb, and stand. There are, moreover, supplementary tables for finding the actual luni-tidal interval and height on a given day, as affected by the half-monthly inequality, and rules and tables for finding the effect of the diurnal inequality, all arranged in a manner easy of comprehension and convenient for use. From the explanations accompanying these tables we learn that the tides on the coast of the United States, on the Atlantic, gulf of Mexico, and Pacific, are of three different classes. Those of the Atlantic are of the most ordinary type, ebbing and flowing twice in 24 hours, and having but moderate differences in height between the two successive high or low waters, one occurring before noon, the other after noon. Those of the Pacific coast also ebb and flow twice during 24 hours, but the morning and afternoon tides differ very considerably in height, so much so that at certain periods a rock which has $8\frac{1}{2}$ feet of water upon it at low tide

may be awash (nearly bare) on the next succeeding low water. The intervals, too, between successive high and successive low waters may be very unequal. At San Francisco, for example, at a time when the moon has a large southern declination, the high water occurring about 12 hours after the moon's transit may mark 5 feet on a tide staff; 5 hours afterward low water will mark $3\frac{1}{2}$ feet, 6 hours after which the second high water will reach $7\frac{1}{2}$ feet, and 7 hours later the second low water will fall to zero. The inequalities depend upon the moon's declination, in the manner which we have explained; they disappear at the time of the moon's declination being nothing, and are greatest about the time of its being greatest. In the gulf of Mexico, from Cape Florida around the peninsula to St. Mark's, the tides

are of the ordinary kind, but with a daily inequality which, small at Cape Florida, goes on increasing westward to the Tortugas. From the Tortugas to St. Mark's the tides have a great resemblance to those of the Pacific coast, though the rise and fall is much smaller. From Cape St. Blas to the Mississippi the tides ebb and flow very regularly only once in 24 hours (single day tides); the small and irregular double tides appear only for 2 or 3 days about the time of zero declination of the moon. To the westward of the Mississippi the mixed type prevails again, and the tides are very small, ranging from 1 to $2\frac{1}{2}$ feet. As the entrances to the ports in that region are for the most part very shallow, a knowledge of these small variations in depth is of no less importance than of the larger tides in the northern ports.

TIDE TABLE FOR THE UNITED STATES.*

* The mean interval in column 2 has been increased by 12h. 57m. (half a mean lunar day) for some of the ports in Hudson river, Delaware river, and Chesapeake bay, so as to show the succession of times from the mouth. For ports in the gulf of Mexico W. of St. Mark's, see remarks preceding this table.

TIDE TABLE FOR SOME OF THE PRINCIPAL PORTS AND HEADLANDS OF THE WORLD, giving the vulgar establishment or time of high water at full and change, and the rise and fall or whole range at spring and neap tides, except for the United States.

Places.	Time of H. W. at full and change.	Range at spring tides.	Range at neap tides.	Places.	Time of H. W. at full and change.	Range at spring tides.	Range at neap tides.

A study of the preceding tables, with the aid of a map, will develop many interesting facts with regard to the propagation of the tide wave and the effect of the configuration of the coasts on the time and height of the tides. It will be seen, for example, that high water occurs nearly at the same time at the headlands of the great middle and eastern bays of the Atlantic coast of the United States—at Cape Hatteras, Nantucket island, and Cape Sable—making an allowance for the difference in local time. If by a line on the map we connect these points at which high water occurs simultaneously, we may regard that line as representing the crest of a tide wave advancing upon the coast. We shall find high water to occur later and later as we go up into the bays and rivers; and by following up the progress of the waves, we may be enabled to draw lines representing the time of high water or the top of the wave for each successive hour. Such lines are called co-tidal lines, and have been traced for the coasts of the United States by Prof. Bache, for which we again refer to the coast survey reports. A chart of co-tidal lines for the British isles, by Prof. Whewell, will be found in Keith Johnston's "Physical Atlas," as well as a chart of co-tidal lines for the whole

globe; the latter must, however, be looked upon as a rather adventurous generalization, in the absence of any positive knowledge of the tides in mid-ocean. The tides about the British isles present a very interesting study. The advancing high water passes up the British channel, occupying 6 hours from the Scilly isles to the mouth of the Thames, where it is met and reinforced by the high water 12 hours older, which has travelled around the isles to the northward and down the German sea. There is a point in the latter, about midway between Yarmouth and the Texel, where the co-tidal line of 9 hours of the latter tide wave intersects that of 3 hours of the former, causing the interference of low water of the one with high water of the other tide, in consequence of which no change takes place in the sea level, as has been ascertained by actual observations over a shoal spot in that locality. A remarkable case of the meeting of two tides occurs near Throg's Neck at the W. end of Long Island sound. The tide wave of the Atlantic enters the sound between Point Judith and Montauk point, and travels westward through the sound, a distance of about 120 miles, in 3½ hours to Sand's Point or Throg's Neck, where it is met by the tide which enter-

ed New York bay off Sandy Hook, about the same time that the former was off Point Judith, and which has advanced but 40 miles in the same time. This remarkably slow transmission of the wave is due to the narrowness and intricacies of the channel through the East river, and especially in Hell Gate, where the tidal current frequently attains a velocity of 6 miles an hour, producing powerful eddies in the angles of the narrow passages, and constituting a noted and much dreaded danger in the navigation of the sound. The removal by blasting of one of the principal rocks obstructing the channel has greatly diminished the danger of the passage. At Montank the mean range of the tide is 2 feet, at Sandy Hook 4.8 feet; the greatest mean range observed is one foot more than the sum, being 7.8 feet at Sand's Point, which increase is due to the contraction of the channel.—The agency of tidal currents in producing changes in the entrances of bays and harbors is a subject of the first importance to commerce and navigation, which has received full attention in the prosecution of the American coast survey. The laws according to which the changes take place require to be studied by long continued observation, and when the change is for the worse, the means of counteracting it must be pointed out. As on the average the same amount of water moves inward and outward with the flood and ebb tides, we might readily suppose that the same amount of material is transported either way, and that no important change would take place in the configuration of the bottom. But the operation of the flood stream is very different from that of the ebb stream. We have as a general feature an interior basin of some extent communicating with the sea by a comparatively narrow passage. The flood stream, therefore, running with considerable velocity through this channel, will as it enters the basin spread out and become slow, depositing the sand and mud it is charged with, and making extensive flats or shoals opposite the entrance. The ebb stream runs slowly over the flats from all directions toward the opening, without removing much of the deposit, and gradually concentrates in definite narrow channels, which it scoops out, and the depth of which will depend in a great degree on the proportion of the area of the basin to the outlet, or, in other terms, on the difference of level which will be reached during the ebb between the basin and the ocean, which determines the greatest velocity and transporting power reached by the ebb stream. Among the most notable and important instances of the effect of tidal currents upon harbors is the advance of Sandy Hook upon the main ship channel into New York bay. Within a century it has increased a mile and a quarter, and at about the rate of $\frac{1}{16}$ of a mile per year in 12 years since 1844. A point where 10 years before there was 40 feet of water, was then nearly bare at low water. The cause of this growth is a remark-

able northwardly current along both shores of the Hook, running both during the flood and ebb tides, with varying rates, and resulting from those tides directly and indirectly. A full discussion of this subject will be found in the coast survey reports for 1856 and 1858.

TIECK, CHRISTIAN FRIEDRICH, a German sculptor, born in Berlin, Aug. 14, 1776, died there, May 14, 1851. He studied under Schadow and David, and first brought himself into notice at Weimar, where in the early part of the present century he executed busts of Goethe, Voss, and other eminent literary men. During a subsequent residence in Italy he was much employed by Mme. de Staël and the crown prince, afterward King Louis of Bavaria, for the latter of whom he executed a series of busts of distinguished Germans for the Walhalla. In 1819 he established himself in Berlin, where he passed the remainder of his life. He participated in most of the important art enterprises undertaken in Berlin during the last 30 years of his life, and was particularly distinguished for his memorial busts. Among his principal works are the friezes, groups for the pediment, and other external decorations of the royal theatre, and a series of seated marble statues of classical personages for the royal palace. Kiss was his pupil.

TIECK, LUDWIG, a German author, one of the founders of the romantic school, brother of the preceding, born in Berlin, May 31, 1773, died there, April 28, 1858. He was educated at the universities of Berlin, Halle, Göttingen, and Erlangen. Shakespeare and mediæval romance were already the chief objects of his admiration and study, and he had published several minor tales and tragedies, when in 1795 appeared his two fantastic novels *Abdallah* and *William Lovell*, the former a chivalric in the guise of an oriental romance, and the latter relating the career of a scornful and incomprehensible genius, superior to the ways and maxims of the world. His antagonism to the literary tendencies of the time was more effectively displayed in *Peter Lebrecht* (1796), and in his *Volkmärchen* (1797), several of which, as *Der gestiefelte Kater* ("Puss in Boots"), *Blaubart* ("Bluebeard"), and *Leben und Tod des kleinen Rothkäppchen* ("Life and Death of Little Red Riding Hood"), combine the simplicity of the old legends with grotesque satire upon modern subjects. The classicists were the special objects of his brilliant railery. A more definite conception of his own poetic and romantic ideal appears in his succeeding works. The *Herzensergussungen eines kunstliebenden Klosterbruders* (1797), the *Phantasien über die Kunst* (1799), both written in conjunction with Wackenroder, and the romance of *Frans Sternbald's Wanderungen* (1798), were panegyrics not only upon the art, but also the manners, literature, and faith of the middle ages. The comedies of *Die verkehrte Welt* ("The Topsy-Turvy World") and *Prinz Zerbino, oder die Reise nach dem guten Geschmack* ("Travels after Good Taste")

abound in humorous and ironical invective against those who prefer the severity of Greek and French taste to the marvels and terrors of mediæval and oriental fancy. The *Leben und Tod der Genevieve* (1800), treating the legend of St. Genevieve, is esteemed his finest drama, though marked by the affectations and irregularity of his school. Meantime he had married at Hamburg a niece of the composer Reichardt, had become associated with the Schlegels, Novalis, and Steffens at Jena, and with Herder at Weimar, and was occupied with a translation of "Don Quixote" (4 vols., Berlin, 1799-1801). He published at Dresden in 1802, with A. W. von Schlegel, the *Musen Almanach*, collected in 1803 the *Minnelieder aus dem Schwäbischen Zeitalter*, to the prevalent admiration of which he had contributed more than any one else, and produced in 1804 the elaborate dramas of *Kaiser Octavianus* and *Fortunatus*. He now rested from composition, applied himself to the study of German mediæval literature, visited Rome to examine the MSS. in the Vatican, and after his return to Munich in 1806 suffered so severely from the gout that he was able to publish nothing for several years. He became intimate with Solger in 1811; collected and modified many of his previous pieces in *Phantasiën* (8 vols., 1812-'15); produced the *Altenglisches Theater* (2 vols., 1811), containing translations of several plays of the age of Shakespeare, *Ulrich von Lichtenstein Frauen-dienst* (1815), and 2 vols. of the *Altdeutsches Theater* (1817); travelled in England to prosecute Shakespearean studies in 1817, and is believed to have attained a more thorough acquaintance with Elizabethan literature than any other foreigner; and on his return took up his residence in Dresden and manifested a revolution in his literary taste. The most ardent promoter of German romanticism abandoned the cause of which he had been the prophet, and began to prefer historical to fantastic subjects, and strict rules of art to the caprices of mystical passion. A society of men of letters and artists gathered about him, whom he charmed by his conversational powers and his recitations of the best dramatic compositions, ancient and modern, which he is said to have rendered with an effect comparable to that produced by Talma. Beside tales for annuals, he published a collection of poems (8 vols., 1821); *Shakespeare's Vor-schule* (2 vols., 1828-'9), consisting of translations of plays which, unlike other critics, he considers to have been probably early works of Shakespeare; and *Dramaturgische Blätter* (2 vols., 1826), containing admirable criticisms of Shakespearean and modern German dramas. His principal later novels, remarkable for their witty and suggestive dialogues on modern literature and life, are: *Der Aufruhr in den Cévennen* (1826), an unfinished romance of the insurrection in the Cévennes; *Des Dichters Leben* (1828), in which Shakespeare and some of his contemporaries are introduced; *Der Tod des Dichters* (1829), founded upon the fate of Ca-

moëns; and *Vittoria Accorombona* (2 vols., 1840), the heroine of which is an adventurous Corinna under the pontificates of Gregory XIII. and Sixtus V. He and his daughter Dorothea assisted Schlegel in his translation of Shakespeare. In 1840 he was invited by Frederic William IV. to Berlin, where he was created privy councillor, and where, as at Dresden, he took an active part in the management of the theatres. By his influence the *Antigone* was successfully produced on the stage both at Berlin and Potsdam. He edited the posthumous works of Novalis (1802) in association with Friedrich von Schlegel, of Heinrich von Kleist (1826), of Solger (1826) with Friedrich von Raumer, and of Reinhardt Lenz (1828). He revised a collected but incomplete edition of his works (20 vols., Berlin, 1828-'49).

TIEDEMANN, FRIEDRICH, a German philosopher, born at Bremervörde, April 3, 1748, died in Marburg, Sept. 24, 1808. At the university of Göttingen he began successively the courses in theology and jurisprudence, but abandoned each for classical literature and philosophy. He became in 1769 tutor in a nobleman's family, returned after 4 years to Göttingen, was recommended by Heyne to the professorship of ancient literature in the Carolinum at Cassel in 1776, and was transferred to the professorship of philosophy at Marburg in 1786. He published dissertations against the system of Kant, several treatises on special subjects in the history of Greek philosophy, *Untersuchungen über den Menschen* (3 vols., Leipzig, 1778), and *Geist der speculativen Philosophie* (6 vols., Marburg, 1791-'6), his principal work, tracing the history of philosophy from Thales to Wolf, which has not yet been entirely superseded.—FRIEDRICH, a German anatomist and physiologist, son of the preceding, born in Cassel, Aug. 28, 1781. He was educated at Marburg, and became professor of anatomy and zoology at Landshut in 1806, and of comparative anatomy, physiology, and zoology at Heidelberg in 1816. The last position he held till 1849, declining invitations to Bonn and to Berlin; and has since lived in retirement at Frankfurt-on-the-Main. He has published works on zoology (8 vols., 1808-'10); on the anatomy of the heart of fishes (1809), of the flying lizard or dragon (1811), and of headless monsters (1818); on the anatomy and history of the formation of the brain in the human fetus (1816); on the structure of radiate animals (1820), which received a prize of 3,000 francs from the French institute; illustrated works on the nerves of the uterus (1822), on the arteries of the human body (1823), and on the brain of monkeys (1822); a treatise on digestion (3 vols., 1826-'7), in conjunction with Gmelin; on the physiology of man (1830 et seq.); on the opening and closing of the arteries in disease (1843); and on living worms and insects in the olfactory organs. With the brothers Treviranus he edited from 1824 to 1835 the *Zeitschrift für Physiologie*.—His son

GUSTAV NIKOLAUS took part in the Baden insurrection of 1849, was the commander of the fortress of Rastadt, and was condemned to death and shot, Aug. 11, 1849.

TIEDGE, CHRISTOPH AUGUST, a German poet, born at Gardelegen, in Brandenburg, Dec. 14, 1753, died in Dresden, March 8, 1841. He studied law at Halle, became a secretary in the administrative council at Magdeburg, and in 1781 went to Ehrich as private tutor, where he was intimate with the poets Göcking, Gleim, Klamer Schmidt, and Elisa von der Recke. He accepted the invitation of Gleim to Halberstadt in 1788, where he resided till he became private secretary to the canon Von Stedern in 1792, in whose family he remained till 1799. At Berlin he renewed his intimacy with Elisa von der Recke, travelled with her through Germany, Switzerland, and Italy (1805-'8), and lived in her house at Berlin, and after 1819 at Dresden, till her death in 1833. By her will she ordered the same establishment to be kept up for him without change during the remainder of his life. His poems are chiefly didactic and elegiac, the most noteworthy being *Urania*, on the immortality of the soul. A complete edition was edited by Eberhard (8 vols., Halle, 1823-'9). See also Eberhard, *Blicks in Tiedge's und in Elisa's Leben* (Berlin, 1844).

TIEN-TE. See CHINA, vol. v. p. 112.

TIEN-TSIN, TIEN-TSIN, or TIEN-SING, a town of China, province of Chi-li, situated on level ground at the junction of the Pei-ho with the grand canal, 70 m. S. E. from Peking; pop. 500,000. It is surrounded by a wall about 4 m. in circuit, and entered by 4 gates, each surmounted by a watch tower several stories high. The principal streets lead from the 4 gates to the centre of the town, and are broad and well paved; and the houses are built of unburned brick or mud and have a mean appearance, though some of them are commodious and well furnished. There are some temples and public offices. The river is crossed by a bridge of boats, and large suburbs extend for a considerable distance along both banks. Tien-tsin derives its importance from being the terminus of the grand canal and the port of Peking, and is said to have formerly been a place of great wealth and extensive trade; but since the banks of the canal were broken by the inundation of the Hoang-ho the trade has declined greatly, and the place has now the appearance of decay. Treaties were concluded here in 1858 between the Chinese government and the plenipotentiaries of England, France, Russia, and the United States, the chief provisions of which were the right of residence for a British minister at the court of Peking, permission for all to send special embassies to the capital and to travel and trade in all parts of the empire, the opening of several new ports, and the settlement of the question of transit dues.

TIERS ÉTAT (Fr., third estate), a name applied previous to the revolution of 1789 to that portion of the French people which was not in-

cluded among the clergy or the nobility, and which comprised $\frac{1}{2}$ of the population. The *tiers état* appears as a third branch of the French states-general as early as the 13th century, and at all meetings was duly represented by its deputies, who however were so greatly outnumbered by those of the other two branches, that the measures voted upon in common were almost invariably decided in favor of the privileged classes. The refusal of the clergy and nobility to reform this abuse by giving the *tiers état* a representation proportioned to their actual numbers accelerated the crisis of the French revolution, to the consummation of which the pamphlet of Sieyès, *Qu'est ce que le tiers état?* greatly contributed. The term is now purely historical.

TIFFIN, a town and the capital of Seneca co., Ohio, situated on both sides of the Sandusky river and on the line of the Sandusky, Dayton, and Cincinnati railroad, 38 m. S. W. from Sandusky City, and 180 m. N. N. E. from Cincinnati; pop. in 1860, 4,500. It has several manufacturing establishments, 5 weekly newspapers and 2 monthly periodicals, 2 banks, a large union school building, the county buildings, and 12 churches. Heidelberg college and theological seminary, under the supervision of the German Reformed church, is at this place.

TIFLIS, or TEFLIS, a town of Asiatic Russia, in Georgia, capital of the government of the same name and of all the Transcaucasian provinces, situated on the river Koor, 1,100 feet above the level of the Black sea, in lat 41° 41' N., long. 44° 50' E.; pop. estimated at 50,000. It stands in a narrow valley midway between the Black and Caspian seas, at the foot of a line of barren hills, with ranges of lofty mountains on both sides. It is surrounded by a wall with 6 gates, has several forts, and is built upon both sides of the river, which is crossed by a wooden bridge. To the southward of the town there are extensive ruins of an old fortress, on a hill nearly 400 feet above the level of the bridge across the Koor. Tiflis has many Greek and Armenian and 2 Roman Catholic churches, some of which are very handsome buildings. There are numerous schools, and several good shops and hotels, in the new town or part chiefly occupied by the Russians. The population is extremely varied, being made up of Tartars, Persians, Lezgians, Circassians, and Russians. Tiflis is celebrated for its warm baths. The mineral springs are chiefly situated at the S. end of the city, and the temperature of the hottest is 115° and that of the coldest 75°. These waters are said to be very beneficial in cutaneous disorders and rheumatic complaints. The climate is exceedingly hot, and bilious diseases prevail. The manufactures consist of carpets, shawls, &c.; and a considerable trade is carried on with Persia. Wine is produced in the neighborhood, but the flavor is not relished by strangers.—Tiflis was founded about A. D. 469 by a monarch named Vakh-tang, who conquered the territory lying be-

tween the lack and Caspian seas, and was the capital of the nominally independent kingdom of Georgia, though devastated by Genghis Khan, and frequently in the possession of the Turks or Persians. Aga Mohammed Khan, shah of Persia, destroyed it in 1795, and reduced a large portion of the inhabitants to slavery. The last king of Georgia ceded it to Russia in 1801, since which its population has more than doubled.

TIGER (*felis tigris*, Linn.), one of the largest, strongest, and most active of the cat family, peculiar to Asia. It is usually about 8 feet long and between 8 and 4 feet high, but is occasionally seen considerably larger than this; the ground color is bright orange yellow, the face, throat, and under parts nearly white, and all elegantly striped with transverse black bands and bars, rendering it one of the most beautiful of quadrupeds; it is less high but longer and more slender than the lion, with rounder head and more cat-like form; the colors are brightest in the adult male, the young being grayish with obscure dusky bands. Having no mane, its appearance is less majestic than that of the lion, and its countenance conveys an impression of treachery and wanton cruelty. Bloodthirsty and ferocious when hungry, it lies in ambush at early dawn by the sides of springs and rivers for animals as they come to drink; it is able to leap a great distance upon its prey, carrying off a buffalo with apparent ease, a powerful man being as nothing in its jaws; its motions are exceedingly supple and graceful; it passes the day for the most part in a shady covert, gorged and sleepy from the morning meal. Its north and south geographical range is extensive, from northern China to the Malay peninsula, but it is most abundant in the vast jungles lining the banks of the great rivers of Hindostan. In many parts of Bengal it is the terror and scourge of villages, prowling around the outskirts, and attacking cattle in the fold and on the road, though the natives protect them in part by noisy drums by day and torches by night; men and women not unfrequently fall victims when they incautiously venture into the jungle. The English rifle has nearly cleared the thickly settled districts from these animals, against which the native traps and weapons (spears and poisoned arrows) are comparatively powerless. Tiger hunting is a favorite sport in India, especially with English officers; the native princes go in great state, mounted on elephants, with a large train of men on foot and on horseback, attended also with dogs; it is an exciting and dangerous pastime, often resulting fatally to men, horses, and elephants. In the East the tiger is considered the emblem of power, and in China the justice seats of the mandarins are covered with tiger skins; the tiger hunters of the native armies are the bravest and best of their soldiers, and a tiger's head, profusely decorated with jewels, is one of the chief ornaments of royal state. The tiger makes no noise com-

parable to the roar of the lion, but rather a loud grunting sound. It may be tamed when taken young, though its temper cannot always be depended on; it was formerly sometimes seen as the apparently gentle and subdued attendant of the Indian fakir; it breeds in captivity, though less frequently than the lion; hybrids between the Asiatic lion and tigers have been born in menageries, but have not reached maturity; their color is brighter and the bands better marked than in young lions or tigers of unmixed race. The tiger was less known to the ancients than the lion and African spotted cats; Aristotle never saw one, and Pliny says that the first one known in Rome was a tame one belonging to the emperor Augustus. For recent and interesting accounts of tiger shooting, the reader is referred to Capt. Shakespear's "Wild Sports of India" (London and Boston, 1860).—The so called American tiger is the jaguar (*P. onca*, Linn.).

TIGER OAT, a name commonly applied to several small species of *felina*, in America, Asia, and Africa, especially to those ornamented by bands and bars. Among the American species, the ocelot has been described under that title, and under the same the margay (*felis tigrina*, Linn.). The *F. eyra* (Desm.) is called tiger cat; it is about the size of the house cat, but with longer neck, body, and tail; it is uniform brownish red, with under jaw and nose spot white, paler below; like the ocelot, it comes from Guiana as far north as Mexico and Texas. The *F. yagouaroundi* (Desm.) is larger, with a much longer body; it is grizzled brownish gray without spots; hairs ringed and tipped with black; the young more rufous; it extends from Paraguay to Texas. Both of these cats frequent woods and thickets, feeding on small mammals and birds, and are excellent climbers. Another South American tiger cat is the chati or chibeguan (*F. mitis*, F. Cuv.), about 21 inches long with a tail of 11; it is pale tawny yellow, white below, with lines of black spots on neck and back and circles of the same on the body and limbs, and tail ringed above with black; it is a beautiful and graceful animal, about 14 inches high, diurnal in habit, of a gentle disposition (whence its specific name), and with a cry somewhat harsher and more prolonged than that of the common cat.—There are several tiger cats in Asia, of which the largest and handsomest is the rimau-daban (*F. macrolepis*, Temm.); it is about 8 feet long, with a tail of 2½ feet more, and 16 inches high at the shoulders; the head comparatively small, ears short and rounded, body cylindrical, limbs very robust, tail very full and long, and fur thick and soft; it is ashy or brownish gray, with irregular spots and bands of velvety blackness arranged longitudinally and unbroken along the back; border of mouth black, and feet gray. It is a native of Sumatra, and lives much on trees, hence called tree tiger; the food consists of birds and the smaller deer; it is not very

common, and not dreaded by the natives except for its visits to their poultry yards; it has none of the fierce expression of the tiger and leopard, and is playful and gentle in captivity. The Javanese or Sumatran tiger cat (*F. minuta*, Temm.) is 2 feet long, of which the tail is 9 inches, and 10 inches high; the color is grayish brown in the adult, the lower parts and inside of limbs white; back marked with lines, sides with irregular blotches, and limbs with small spots of dark brown; tail imperfectly ringed, black at tip; the young are reddish brown, paler below, with rows of lengthened spots on back and sides, smaller and more numerous on limbs, and no black at tip of tail. It inhabits the extensive forests of Sumatra and Java, remaining concealed in hollow trees during the day, prowling at night in search of food, and often committing depredations on men's roosts; it feeds principally on small mammals, but if hard pressed will eat carrion; it is fierce, untamable by confinement, and very shy and cunning. Diard's tiger cat (*F. Diardi*, Desm.), also from Java, is 3 feet long, of which the tail is 16 inches; it is yellowish gray, with spots and rings of black, resembling the ocelot in the enclosed spots on the sides, and the rufous-daban in the ample fur of the tail and the distribution of the markings. The Nepaul tiger cat (*F. Nepalensis*, Vig. and Horsf.) is 3 inches long, with a tail of 11; the color is ashy gray, nearly white below, the markings of back in irregular lines, of body in angular blotches, and of legs in blackish spots; the form is long and civet-like, head small, and neck and tail comparatively slender and lengthened; it has been placed by some in the genus *riodon* (Horsf.), one of the connecting links between the civet and the cat families.—The animal commonly called tiger cat by the furriers has been described under *Serval*, an African species.

TIGER MOTH. See MOTH.

TIGHE, MARY (BLACKFORD), a British authoress, born in Dublin in 1774, died in Woodstock, Kilkenny co., March 24, 1810. She was married in 1793 to her cousin, Henry Tighe of Wicklow co., a member of the Irish parliament, and in 1805 printed for private circulation her "Psyche," a poem in the Spenserian stanza, founded on the story of Cupid and Psyche as related in the "Golden Ass" of Apuleius. It passed through several editions in her lifetime. She died of consumption after several years of uninterrupted suffering, and is commemorated by Moore in the well known lyric commencing, "I saw thy form in youthful prime." In 1811 appeared a complete edition of her poetical works, containing many pieces of a devotional character written during her last illness.

TIGRANES I., a king of Armenia, who succeeded the throne about 96 B. C., and died about 55. He was a descendant of Artaxias, the founder of the Armenian monarchy, and by wars during the early part of his reign united all Armenia under his rule, and con-

quered in addition several provinces. He enlarged his dominions still more by conquest from the Parthians, and assumed the title of king of kings, and in public always appeared attended by tributary princes. Early in his reign he married Oleopatra, daughter of Mithridates, king of Pontus, with whom he formed an alliance. The dissensions which distracted Syria opened a fair field for his ambition, and enabled him by 88 B. C. to gain possession of that country from the Euphrates to the sea, of which he held undisputed control until 74, when his alliance with his father-in-law brought him into conflict with the Roman power. At the instigation of Mithridates, he marched into Cappadocia at the head of a vast army, reduced that country, and carried off 300,000 of the inhabitants, many of whom he settled in his new capital, Tigranocerta. Mithridates, who had derived little support from his son-in-law, was at length obliged to flee to him for refuge; and to the haughty demand of Appianus Clodius, the ambassador of the Roman general Lucullus, that the fugitive king should be given up, Tigranes replied with a declaration of war. Lucullus crossed the Euphrates and Tigris, marching into the interior of Armenia, utterly defeated an army of 150,000 foot and 55,000 horse, and took possession of Tigranocerta. Tigranes prepared to collect a new army, and both he and Mithridates labored, though without success, to bring Phraates, king of Parthia, into an alliance; on the other hand, many princes of the neighboring countries submitted themselves to the Romans, and Antiochus Asiaticus was placed upon the throne of Syria. In the summer of 68 Lucullus again totally routed the Armenian forces on the river Arsianias, and was only prevented by the disaffection existing among his troops from making himself master of Artaxata, the ancient capital of the country. All the advantages which might have been derived from this victory were destroyed by the conduct of the Roman troops, whose mutinous spirit was said to have been secretly fomented by Pompey. Lucullus was compelled to retreat, his lieutenant L. Fannius was defeated, and a great part of the former possessions of Tigranes came again into his power. In 66 Pompey arrived to take the supreme command, and in a great battle on the Euphrates defeated Mithridates, who had been seeking to recover his lost dominions. At the same time a son of Tigranes of the same name had engaged in a conspiracy against the life of his father, and being discovered had fled to Phraates, who readily embraced his cause and marched an army into Armenia, which advanced near Artaxata and then retired without taking that city. Tigranes was easily able to drive out his rebel son, unsupported by a foreign force; but suspecting his father-in-law to have been engaged in the conspiracy against his throne, he refused to receive him after his defeat and flight, and even set a price of 100 talents on his head. As the Roman army un-

der the guidance of his son was rapidly approaching Artaxata, he repaired in person to the camp of Pompey, and placed himself as a suppliant at the feet of that general. Pompey would not accept the diadem which he offered him, and treated him in a friendly manner, placing him on the throne of Armenia proper with the exception of Gordyene and Sophene, which were made a separate kingdom to be governed by the young Tigranes. The old king gave the Roman general 6,000 talents, and also subsidized the Roman troops; and remaining faithful to the Roman cause, he received in 65 the provinces of Gordyene, which had been seized by Phraates. In 64 he was again at war with the king of Parthia, but the differences between them were composed by the intervention of Pompey. After this he disappears almost entirely from history. He was succeeded by his son Artavasdes.

TIGRÉ, a district of Abyssinia, lying between lat. 12° and 15° 30' N., and long. 37° 25' and 40° 15' E. It is an elevated plain which forms the basis of several mountain chains, the principal of which are the Samen and the Taranta ranges, the latter being also called the Haramat. The Samen runs from N. E. to S. W., separating the Atbara and Bahr-el-Azrek, and has several summits from 12,000 to 16,000 feet high. The Taranta range follows the line of the N. E. coast, separating the basin of the Tacazze from the Red sea; its highest summits do not much exceed 7,000 feet. The plateau itself is from 3,500 to 7,000 feet in elevation. The deep ravines which separate these mountain chains are the beds of rivers of considerable size. The Tacazze is second only to the Bahr-el-Azrek in size among the rivers of Abyssinia. The Mareb and the Guenqua are the other principal rivers. Tigré is divided into 18 petty chieftaincies or districts; the principal towns are Antalo, the capital, Tackeraggiro, Sokota, Axoom, Adowa, and Dixaur. Adowa is the largest town of the country, is the entrepot of trade on the great caravan route between Massowah and Gondar, and has considerable manufactures.—The district was for many years an independent kingdom, and was governed by a king named Ubye; but in 1854 Theodoros, king of Abyssinia, conquered it, taking Ubye prisoner, and still holds it as a province of his empire.

TIGRIS, the second river of western Asia, rising in the southern slope of the Armenian chain of the Taurus, E. of Malatiah on the Euphrates, and taking a S. course to Diarbekir, whence its direction is S. E. to Mosul, and thence S. by E. to its junction with the Euphrates at Korna, where the two form the Shat-el-Arab. At its source it is not more than 10 m. distant from the Murad or E. branch of the Euphrates, and for 80 m. below Bagdad it is parallel with the Euphrates itself, being not more than 80 m. distant, and separated by a range of hills. It then diverges to the east, and for the rest of its course till near its jun-

tion is from 80 to 100 m. distant from that river, to which however it is united by several canals. Its total course is estimated at 1,150 m., and its width from Mosul to Bagdad, a distance of about 220 m., averages 200 yards; its current in March flows 4½ m. an hour. It is subject to annual floods, when it overflows its banks, especially in the lower part of its course. The greatest height is attained in the latter part of May, and it resumes its usual level by the middle of June. It is navigable between Diarbekir and Mosul for rafts at certain seasons of the year; below Mosul it is navigable for steamers at all seasons. Between the Euphrates and Tigris lies the once fertile and populous region formerly known as Mesopotamia, and near its source was, according to some, the lost Eden. Wars and bad government, the neglect of irrigation, and some changes in the course of the river, have reduced this region, once the garden of western Asia, to a desert. The banks of the Tigris are deserted, and except in the vicinity of Diarbekir, Mosul, and Bagdad, the only inhabitants are members of nomadic Arab tribes. The ruins of Nineveh, Seleucia, Otesiphon, Opis, &c., are on its banks; and the discoveries of Rich, Botta, Layard, Rawlinson, and Lobdell were made in the mounds of ruins which line its shores. (See EUPHRATES.)

TILE, a thin sheet of baked clay, flat or curved, used for covering floors, roofs, or the walls of buildings, and also by the ancients for the flues of baths and for drains. In ancient times tiles were used by the eastern nations of a great variety of sizes and for numerous purposes, the Assyrians even employing them as tablets for writing. Upon flat slabs of fine terra cotta and upon cylinders and prisms of the same material, or sometimes of glazed ware, they impressed with extreme neatness characters which remain to this day among the most imperishable monuments of antiquity. The Egyptians employed tiles for the same purpose, but wrote upon them with black ink with a reed, while the Assyrians indented the characters with a sharp instrument in the soft clay before it was baked. The roofing tiles were sometimes flat and laid overlapping each other like slates; but they were more generally of the semi-cylindrical form, laid in rows up and down the roof, the rows having the concave side upward holding the alternating rows laid with the convex side upward. The Greeks used large flat roofing tiles, sometimes having flanges, with semi-cylindrical ones laid over their lines of junction. The flat tiles were often stamped with brief inscriptions, and the others were ornamented with painted devices. The Greeks employed tiles for flues of baths, in the construction of tombs, and for drains. The Romans used them still more generally, and their name, *tegula* (from *tegere*, to cover), came to be applied even to bricks, which were much more used than tiles; the real distinction between them is in the greater fineness of the tile. The roofing tiles were, like some of those

of the Greeks, large and flat, furnished with langes rising about $2\frac{1}{2}$ inches above their surface, which when two adjacent tiles were set together were overlapped by the arched tile or *imbrez* set over them. Flat tiles alone were also used for covering roofs. It was customary to stamp the tiles with inscriptions designating the potter, the manufacturer, the name of the state which supplied the clay, the name of the emperor or of the consulship, and various other matters. They thus have often served as records of important historical events. As to covering of interior walls, the tiles used by the Romans were large thin squares of terra cotta, generally ornamented on one side with incised devices. The tessellated pavements were formed of small cubical tiles known as *mosællæ* (the diminutive of *tessera*, from the Gr. *τετραπῆς*, four, having reference to their shape). Some of these were not more than $\frac{1}{4}$ of an inch square, and they were laid to form mosaics after various designs. The Romans, like the more ancient nations, made use of large flat tiles in the construction of their graves, and also as we use gravestones for receiving monumental inscriptions. In modern times tiles are used for coverings of roofs, chiefly in warm countries, their weight rendering them objectionable where much snow falls. Snow moreover is apt to be driven up under them, even though they exclude rain perfectly well. Glazed tiles several inches square, variously colored and ornamented, arranged in patterns, are much used for the floors of public buildings and the better class of private houses. (See *ECCLASTIC TILES*.) In the last century it was very much the fashion to adorn fireplaces with a row of porcelain pictured tiles on each side and over the top. Among the devices were often seen series of quaint illustrations of scripture events, of *Æsop's fables*, &c.

TILGHMAN, WILLIAM, an American jurist, born in Talbot co., Md., Aug. 12, 1756, died in Philadelphia, April 30, 1827. He studied law in Philadelphia, and was admitted to the Maryland bar in 1783. In 1793 he returned to Philadelphia, and practised his profession in that city till 1801, when he was appointed chief judge of the circuit court of the United States. In 1802 the law establishing this court was repealed, and Mr. Tilghman returned to the practice of the law till 1806, when he was appointed president of the courts of common pleas in the first district; and in 1806 he was elected chief justice of the supreme court of Pennsylvania. In 1809 he made an elaborate report on the English statutes in force in Pennsylvania; and his only other published work is a "Eulogy on Dr. Caspar Wistar."

TILLANDSIA, a genus of singular plants of the natural order *bromeliaceæ* or pineapple family. The name was given to them by Linnaeus in memory of Dr. Elias Tillands, a professor at Abo in Sweden, and was intended to be suggestive of his aversion to travelling by water from their thriving best in arid situations.

There are numerous species, and most of them belong to South America. According to Dr. Chapman, in his "Flora of the Southern United States," there are at least 8 species at the South. The long moss (*T. usneoides*, Linn.) is found hanging from the live oak and other trees in humid districts from North Carolina to Florida. It is a perennial, its small fine roots penetrating the fissures of the bark; its stem thread-like, long, covered as well as the leaves with membranaceous scales dotted in the centre; the centre of the stem and leaves composed of a filiform, black, horny thread; the flowers solitary, axillary, sessile, with 3 or 4 bracts at base; calyx and corolla divided nearly to the base, segments lanceolate, corolla 8-cleft, campanulate. In winter the plant affords a scanty fare for cattle; and the stems, beaten until the bark peels off, are used for stuffing mattresses, &c., instead of horse hair, which they much resemble.—The tillandsias are all parasitical; some are remarkable for their showy flowers, others for their long, serrated, and stiff leaves, hollow at the base. Under cultivation in the greenhouse or parlor window, they only require a piece of wood or a basket of rotten chips, in which they will thrive.

TILLEMONT, LOUIS SÉBASTIEN LE NAIN DE, a French historian, born in Paris, Nov. 30, 1687, died Jan. 10, 1698. He was educated at Port Royal, studied logic, theology, and ecclesiastical history, and at the age of 23 entered the episcopal seminary of Beauvais, where he remained 4 years. He became a subdeacon in 1672 and a priest in 1676, when he went to reside with the recluses at Port Royal; and after that establishment was broken up in 1679, he retired to his estate of Tillemont, between Vincennes and Montreuil, which he never again left except for a visit in 1681 to his friend Arnauld and the other refugees in the Netherlands. His principal works are: *Mémoires pour servir à l'histoire ecclésiastique des six premiers siècles* (16 vols. 4to., 1698–1717), and *Histoire des empereurs et des autres princes qui ont régné durant les six premiers siècles de l'église* (6 vols. 4to., 1698–1738). His *Vie de St. Louis* was first published in 1847.

TILLER. See STEERING APPARATUS.

TILLOCH, ALEXANDER, LL.D., a Scottish inventor and philosopher, born in Glasgow, Feb. 28, 1759, died in Islington, London, Jan. 26, 1825. He was brought up to the business of his father, a tobacconist, but paid most attention to mechanical and scientific pursuits. In connection with Foulis, a celebrated Glasgow printer, he improved Ged's method of printing from casts of whole pages of type, but failed to render stereotype printing practicable at that time, though his suggestions to Earl Stanhope, 80 years later, may have led to its success. After carrying on the printing business for some years in Glasgow, he removed to London in 1787, and in 1789 purchased the principal part of the "Star" newspaper, which he edited till 1821. He devised a plan of print-

ing bank notes by which their forgery could be prevented, but could not induce the government to adopt it, and was not allowed to accede to proposals from the French republic for its employment in the printing of assignats. In 1797 he commenced the "Philosophical Magazine," which he published and edited alone till a few years before his death. In 1824 he started a third periodical, the "Mechanics' Oracle," which did not long survive his death. Among his other pursuits was the investigation of the prophecies and the Apocalypse, on which he published several dissertations, one of which bears the title of "Dissertations introductory to the Study and Right Understanding of the Language, Structure, and Contents of the Apocalypse" (8vo., 1823). Dr. Tilloch was a dissenter, and for many years preached to a small body called Christian Dissenters, in Goswell street road. He was a member of many scientific societies in Great Britain and on the continent.

TILLOTSON, JOHN, an English pulpit orator and prelate, born at Sowerby, near Halifax, in 1680, died in London, Nov. 22, 1694. His father, a clothier, was a strict Calvinist. At an early age Tillotson became a student in Clare hall, Cambridge, where he was made a fellow in 1651, and remained till 1657, when he became tutor in the family of Prideaux, Cromwell's attorney-general. While a student, the reading of Chillingworth's writings had converted him from Puritanism, and at 30 years of age he took orders in the English church. His success was speedy, and his fame as a preacher soon gave him a choice among preferments. He was successively curate of Cheshunt, rector of Keddington, and preacher at Lincoln's Inn in London, and finally drew crowds to his lectures in St. Lawrence's church, Jewry, in that city. As a champion of the Protestant party, Tillotson was led to oppose the proclamation of Charles II. for liberty of conscience, which made him unpopular at court; and the offices of dean of Canterbury and prebendary of St. Paul's, which Tillotson obtained, were reluctant concessions to his popularity rather than hearty gifts. Tillotson preached earnestly against popery, advocated the exclusion of the duke of York, and prepared the way by his personal influence for the change of rulers. He was the leading member of the commission of 20 divines appointed in 1689 to examine and revise the liturgy. On the accession of William III. he received the office of dean of St. Paul's, and in 1691 was made archbishop of Canterbury. His only legacy to his widow was his collection of manuscript sermons, for the copyright of which she received 2,500 guineas. They are rather moral essays than doctrinal sermons, and deal with ordinary duties and interests more than with the high themes of religious discourse. Their peculiar merits are clearness and moderation, both in statement and argument, and liberality of tone. Indeed,

the tone of Tillotson's sermons goes far to justify the charges brought against him of lax orthodoxy. Few prelates had warmer friends or more bitter enemies. His marriage with a niece of Cromwell brought him into intimate connection with Wilkins, bishop of Chester, whose posthumous works he edited. His funeral sermon was preached by Bishop Burnet, his special friend. His life was written by Dr. Thomas Birch (8vo., London, 1752). His sermons were published in 1704 in 14 vols., and in 1757 in 13 vols., and were translated into German by Mosheim. His complete works were published 1718 in 9 vols. During his life he published in folio 54 sermons, and the "Rule of Faith," in 4 parts (2d ed., 1699).

TILLY, JOHN TZEKELAS, count of, a German soldier, born in the castle of Tilly, Brabant, in 1559, died at Ingolstadt, April 30, 1632. He was educated at a college of Jesuits and imbibed their religious principles, but left their order to enter military service. He fought in the Netherlands under the duke of Alva, Don Juan of Austria, and Alexander Farnese; then went to Hungary, where, under the duke of Mercœur, he distinguished himself against the Turks. In this war he reached the rank of general of artillery. In 1609 he entered the service of Duke Maximilian of Bavaria, who appointed him field marshal, and intrusted him with the reorganization of his army. On the opening of the 30 years' war he was placed at the head of the Catholic army, and contributed to the victory of Weissenberg, near Prague, Nov. 8, 1620; in 1621 took the strongholds of Pilsen and Tabor, which belonged to Count Ernest of Mansfeld, the staunchest supporter of the Protestant cause, and defeated the margrave of Baden on the banks of the Neckar; and in 1622 expelled Prince Christian of Brunswick from the Palatinate, worsting him at Höchst, June 8, and routed his army once more at Stadtloos in Aug. 1623. When Christian IV. of Denmark joined the German Protestants, he gained a great victory over that prince at Lutter, in Aug. 1626, and forced him back to his kingdom. A little later, notwithstanding the reinforcements the Danish king had received from England and France, Tilly besieged Nordheim, which he took after a hard struggle, crossed the Elbe, subdued the continental part of Denmark, and concluded with him the peace of Laback, May 12, 1629. In the following year, Wallenstein being deprived of his power, Tilly, who was already the general of the Catholic league, received the chief command of the imperial troops, and had now to oppose King Gustavus Adolphus of Sweden. He marched against the city of Magdeburg, which had entered into an alliance with that prince, carried it by storm, May 10, 1631, and allowed his infuriated soldiers to sack it in the most dreadful manner; it was reduced to ashes, and 30,000 persons were slaughtered. This act of vandalism excited

universal indignation and horror. He met Gustavus at Breitenfeld, near Leipsic, Sept. 7, 1631, was terribly defeated, losing 7,000 killed and 5,000 prisoners, and fled with the miserable remains of his army. "The old corporal," as the king of Sweden called him on account of his being a strict disciplinarian, the man who had never before been conquered, lost his *prestige*, and soon after his life, dying of a wound received while attempting to oppose the passage of Gustavus across the Lech, April 10, 1632.

TILSIT, a town of Prussia, in the province of East Prussia and government of Gumbinnen, situated on the left bank of the lower Niemen or Memel at its junction with the Tilsa, 60 m. N. E. from Königsberg; pop. in 1858, 13,748. The Memel is crossed by a bridge of boats 1,150 feet long; and the town consists of one principal long wide street lined with good houses. It has a castle erected in 1587, several churches, a gymnasium, infirmary, workhouse, hospital, schools, and numerous charitable institutions. The manufactures include woollen goods, leather, hardware, and arms. The river is navigable up to the town. Napoleon met the emperor of Russia and the king of Prussia upon a raft moored in the centre of the river, a little below the town, June 25, 1807, and the three there signed the treaty of Tilsit.

TIMANTHES, a Greek painter, born probably in Cynthus, flourished about 400 B. C. He was a contemporary of Zeuxis and Parrhasius, and one of the most celebrated artists of antiquity. Only 5 pictures by him are mentioned by ancient authors. Of these, 2 gained prizes in competition with Parrhasius and Colotes; and one of them, representing the sacrifice of Iphigenia, has been perhaps the subject of more criticism than any other ancient work of art. The representation of Agamemnon concealing his face in his mantle, though highly lauded by the ancients as a method of expressing grief, has been objected to by several modern writers, including Sir Joshua Reynolds, as a "trick" of the painter. Fuseli, however, ably vindicates Timanthes in hiding the face of Agamemnon, "not because it was beyond the possibility, but because it was beyond the dignity of expression."

TIMBER. See WOOD.

TIMBS, JOHN, an English author, born in London, Aug. 17, 1801. In 1827 he became the editor of the "Mirror," a low-priced weekly journal, which was remarkable as one of the first attempts to found the now popular cheap press; but he is chiefly known by his historic compilations. He published in 1855 a volume entitled "Curiosities of London," a compendium of antiquarian and local information respecting the English capital. This was followed by "Things Not Generally Known," a series in 5 volumes; "School Days of Eminent Men;" "Stories of Inventors and Discoverers, and Anecdote Biography" (4 vols.). He has edited the "Arcana of Science" and the "Year Book of Facts in Science and Art"

(1839 *et seq.*), and was also for many years sub-editor of the "Illustrated London News," but withdrew from that journal in the beginning of 1858.

TIMBUCTOO, or TOMBUCTOO, a town of central Africa, on the borders of the Sahara, about 9 m. from the river Niger or Quorra, in lat. 18° 4' N., long. 1° 45' W.; pop. about 18,000, greatly increased during the season of trade, from November to January. It is surrounded by a clay wall, about 8 m. in extent, built in the shape of a triangle. The houses are closely packed together, and mostly built of clay and stone; some of them are two stories high, and show considerable taste in their decoration. The port of Timbuctoo is at Kabra on the Niger, which has a vast artificial basin, and is accessible for only 4 or 5 months in the year; but the most valuable traffic is by caravans, for which Timbuctoo is the central station of N. Africa. Gold dust is the great article of trade, but many native products and foreign manufactures are also found here. The merchants of Timbuctoo are generally only agents of those at Mogadore, Morocco, Fez, &c.; and this, with the incessant conflicts of race and religion, prevents the accumulation of wealth here. It has a mixed population of indigenous negroes, Tuarika, Bambaras, Mandingos, Arabs, and Foola, the governing race. Its origin dates from the 12th century, but it was long known in Europe only by reports of native travellers, until it was first reached by Major Laing in 1826, and furtively visited by Caillié in 1828. In 1853 Dr. Barth resided there nearly a year, and has given full details upon it.

TIMOLEON, a Corinthian general, liberator of Syracuse, born about 894 B. C., died in 387. He belonged to one of the noblest families of Corinth, and from early youth was distinguished for his hatred of tyranny and his courage. His elder brother, Timophanes, was an energetic and ambitious man, and occupied a high station in the military service of the Corinthians; and in a battle against the Argives and Cleonseans, while holding the command of the cavalry, he was thrown from his horse, and would have been killed but for the devotion of Timoleon. The Corinthians afterward equipped a standing force of 400 mercenaries, placed them in the citadel as a garrison, and gave the command to Timophanes, who immediately took the supreme power into his own hands, and perpetrated various acts of cruelty. Timoleon remonstrated with his brother to no purpose. A second time he went to the acropolis attended by some friends, and when he found his pleading of no effect, his companions with his concurrence slew Timophanes. The people of Corinth, thus unexpectedly freed from an odious tyranny, were divided between admiration for the patriotism and horror at the fratricide; but the former feeling was largely preponderant. His mother, however, cursed her son, and in spite of his earnest entreaties refused to see him again. The life of Timoleon

was now embittered by the imprecations of his mother and the reproaches of the minority, and it was only through the appeals of his friends that he was prevented from executing his design of starving himself to death. Twenty years passed by, according to Plutarch, and he refused to bear any important office in the Corinthian service. In 844 Syracusan envoys reached Corinth asking for aid for Sicily, which since the death of Dion had been rent by internal dissensions, and was now in addition threatened with subjection to Carthaginian rule. The assistance solicited was granted, but no leader could be found to undertake the apparently hopeless task; and while the archons doubted whom to choose, an unknown voice in the crowd called out the name of Timoleon. He accepted the command, and immediately set about preparing for the expedition; but his means were limited, and at last he set sail with only 10 triremes, having on board 1,000 men, chiefly mercenaries. In the mean time Hicetas, tyrant of Leontini, one of those who had sent to Corinth for aid, had formed an alliance with the Carthaginians against Dionysius the Younger, and endeavored to prevent Timoleon's entry into Sicily. But the latter eluded him and the Carthaginian ships by a stratagem, landed at Tauromenium, and was hospitably received by Andromachus. The first opportunity for active operations came from the town of Adranum, 40 miles distant, which was divided into two parties, one of which sent for aid to himself and the other to Hicetas. The latter was nearer, and reached the city with 5,000 men; but his force was suddenly attacked and put to flight by the troops of Timoleon, who had made a rapid march by the shortest but most rugged route. The victory enabled him to form an alliance with several of the cities of Sicily, and with reinforcements to march his army under the very walls of Syracuse, of all which Hicetas had control except the island of Ortygia, in which Dionysius lay encamped, and blockaded by the Carthaginian fleet. Dionysius at once gave up to Timoleon the island, with its garrison, arms, and magazines, and sailed for Corinth. There the news of the great success of Timoleon excited the highest enthusiasm; 2,000 hoplites and 200 horsemen were instantly voted and equipped, but were for some time prevented from reaching Sicily by a Carthaginian squadron. In the mean while the Corinthian leader retired to Adranum, while Hicetas, with a fleet of 150 Carthaginian triremes and a land force of 60,000 men, prosecuted the attack on Ortygia. But as supplies stole in from Oatana to the relief of the garrison, it was determined to employ a part of the besieging force in the reduction of that place. While they were gone, Neon, the commander of Ortygia, attacked the blockading force, and gained possession of the section of the city called Achradina, which he joined to Ortygia and fortified. The force that had gone forth to attack Oatana returned immediately, while Timoleon at the head of 4,000 men

marched from Adranum. Mago, the Carthaginian commander, now began to distrust Hicetas, and soon sailed away with his whole fleet and all his troops; and the portion of the city held by Hicetas was taken without the loss of a single man. Timoleon was now complete master of Syracuse, and could easily have made himself tyrant; but he at once called together the inhabitants for the purpose of demolishing the strongholds and fortifications erected by former rulers, and upon their site built courts of judicature. The city had been so deserted and impoverished by civil and foreign wars, that, according to the statement of Plutarch, the market place served as a pasture for horses. A democratic constitution, based upon that of Diocles, subverted 70 years previously by Dionysius the Elder, was established, and 60,000 immigrants and restored exiles came to repopulate the deserted town. But the Carthaginians, indignant at the return of Mago, prepared for another invasion; and an army of 70,000 men, led by Hasdrubal and Hamilcar, landed in 889 at Lilybæum. Among them was a body of 10,000 native infantry, one fourth of which constituted the sacred band. The inhabitants were panic-struck, and it was with difficulty that Timoleon could assemble 12,000 men for resistance. Even with this small force he determined to attack the enemy on their own ground, and accordingly set out for the western portion of the island. He reached an eminence overlooking the Crimissus just as the Carthaginians were crossing that stream, and, befriended by a violent storm which pelted the enemy directly in the face, completely routed them. The slaughter of the Carthaginians was terrible, their camp, their baggage, and immense plunder falling into the hands of the conquerors. After this victory he returned to Syracuse with a portion of his troops, and prepared to overthrow Hicetas and Mamercus, tyrants of Leontini and Oatana, the latter of whom was also allied with the invaders. Carthage despatched to their assistance a body of Greek mercenaries under Gisco, and the troops of Timoleon suffered several partial defeats, though not while under his personal command. Hicetas invaded the territory of Syracuse; but on his return he was attacked and utterly defeated, Leontini was captured, and the tyrant with his son and the leader of his forces were taken and put to death. His wife and daughters were carried to Syracuse, and were there sacrificed by the inhabitants for the previous crime of Hicetas in putting to death the female relatives of Dion. Although Timoleon was not directly responsible for this judicial murder, his sanction of it is the greatest stain upon his conduct. He now turned his arms against Mamercus, whom he defeated near the river Abolus; and the loss of the Carthaginian auxiliaries was so serious that Carthage concluded a separate peace, and Mamercus fled to Messana, which was besieged and taken. Mamercus gave himself up, and was tried by the

Syracusan people, and executed. In this work of dethroning tyrants Timoleon proceeded until there were none left in the Grecian portion of Sicily. He now laid down his command both civil and military, and became a private citizen of Syracuse, the inhabitants of that city voting him a house and a landed property, where he resided, bringing his wife and family from Corinth. Yet, though he had given up his power, his character and moral ascendancy were so great that he exercised all the functions of a real ruler throughout Grecian Sicily. Cities were repeopled, constitutions were modified, and public decisions were made in accordance with his advice. This was more especially the case in Syracuse, where he never interfered in political matters except in times of serious difficulty, and where his counsel was usually followed without discussion. Toward the close of his life he became totally blind. His funeral ceremonies were celebrated with great magnificence, and as his body was about to be burned the herald Demetrius made the following announcement: "The Syracusan people solemnize, at the cost of 200 minæ, the funeral of this man, the Corinthian Timoleon, son of Timodemus. They have passed a vote to honor him for all future time with festival matches in music, horse and chariot races, and gymnastics, because, after having put down the despots, subdued the foreign enemy, and recolonized the greatest among the ruined cities, he restored to the Sicilian Greeks their constitution and laws." Timoleon is one of the noblest characters in ancient history, and the interval of freedom which Sicily enjoyed from his arrival to the usurpation of Agathocles was due solely to his efforts. His life was written by Nepos and Plutarch.

TIMON, called **THE MISANTHROPE**, an Athenian who lived in the latter part of the 5th century B. C. In consequence of ingratitude experienced from those he had benefited, and of disappointments in friendship, he secluded himself from the world, and, except Alcibiades, admitted no one to his society. He is said to have died from a broken limb which he refused to suffer a surgeon to set. He is the subject of Shakespeare's "Timon of Athens."

TIMOR, or **TIMUR**, an island situated near the S. E. part of the Indian archipelago, extending in a N. E. and S. W. direction about 300 m., with a breadth varying from 40 to 60 m.; lat. of S. end, 10° 24' S., long. 128° 32' E.; area estimated at 12,200 sq. m.; pop. about 200,000. The native chiefs on the W. and S. coasts acknowledge the supremacy of the Dutch, who have their chief settlement at Coepang; while those on the E. and N. pay tribute to the Portuguese, who have established themselves at Delli. The coasts are not much indented by bays, but the harbors of Coepang and Delli are safe and commodious. The shores are lined in many places by rocks and sand banks; and several islets intervene between Timor and the island of Flores to the W. and New Guinea to

the E., which are respectively distant 100 and 440 m. The island is traversed throughout its length by a mountain chain, which attains a height in the north of about 6,000 feet. Numerous offsets extend to the coasts on both sides, so that the surface is almost entirely occupied by mountains separated from each other by narrow valleys; but there are considerable tracts of level ground near the head of Coepang bay, one of which is about 10 m. square. The rivers are all short mountain torrents; many of them become dry in summer, and the water of all is unwholesome. Traces of volcanic origin are apparent in several places, and the island is subject to frequent earthquakes, the most destructive of which on record took place in 1794, when the church and other buildings at Coepang were thrown down. The mountains are generally bare and rocky, but in places there are forests of considerable extent. Gold, copper, and iron have been found in small quantities. In many places the land is barren, and the vegetation differs considerably from that of the western islands of the archipelago, but partakes very much of the character of that of N. Australia. The palms are few in number, and many of the rich fruits of the western islands are not found here. The animals found on the N. W. side of the central range of mountains resemble those on the western islands of the archipelago, but those on the opposite side are strongly allied to the fauna of Australia. The domestic animals have all been introduced, but with the exception of the horse and buffalo none of them are very numerous. Fish are plentiful on the coasts; pearl oysters are found in some places, and a kind of coral much prized by the Japanese is procured on the reefs. The people live chiefly by hunting. The women weave cloth, and the only manufactures which the men engage in are the construction of canoes and ornaments for their horses. The inhabitants are of low stature, with very dark complexions and bushy hair. A considerable trade is carried on, principally from Coepang, and is chiefly in the hands of the Chinese. Timor appears to have been well known to the Malays and Javanese, who traded to it, long before the arrival of the Portuguese in the eastern seas.

TIMOTHEUS, an Athenian general, died in Chalcis 854 B. C. He was the son of the general Conon, and first comes into public notice in 878 B. C., when, along with Iphicrates and Callistratus, he was made general of the fleet which was engaged in bringing over the islands and maritime cities to the Athenian confederacy, in which undertaking he was especially successful. In 875 he was sent with a fleet of 60 triremes to move about the Peloponnesus and alarm the coasts of Laconia, and by the justness of his dealings and the fairness of his professions gained over numerous allies to the Athenian cause. Near Alyzia he was attacked by a Spartan fleet, which he defeated. The next year, peace being made be-

tween Athens and Sparta, he was recalled; but in consequence of his stopping on his way home at Zacynthus and forcibly restoring some democratic exiles, war was again declared. In 378 he was appointed commander of a fleet to be sent to the relief of Corcyra, but in order to obtain seamen and funds was obliged to make a preliminary cruise among the insular allies, remaining absent so long as to endanger the loss of Corcyra. His appointment was consequently cancelled, and an accusation was entered against him, which was tried in November at Athens, Alcetas, tyrant of the Molossians, and Jason, king of Phæra, appearing as witnesses in his favor. He was acquitted, and in the spring of 372 accepted the command of the Greek mercenaries serving under Artaxerxes II. of Persia against Nectanebus I. in Egypt. Soon after returning from this war, he was sent by the Athenians with an armament to the coast of Asia Minor to assist Ariobarzanes, satrap of Phrygia; but finding that the latter was in revolt against Artaxerxes, he refused him direct aid in accordance with his instructions, but turned his force against the island of Samos, of which he became master after a siege of 10 or 11 months. In return for this conquest, which really shook the authority of Artaxerxes and aided the revolt of Ariobarzanes, the latter made over to him Sestus and Crithote, which secured to the Athenians a partial control of the Hellespont and the occupation of a large surrounding territory. Timotheus was then appointed in place of Iphicrates to an extensive command, including Macedonia, Thrace, and the Chersonese. With the aid of Macedonia he reduced Torone, Potidæa, Pydna, Methone, and various other cities belonging to the Olynthian confederacy, but was unsuccessful in the attack upon Amphipolis. In 363-362 he proceeded against Cotys, king of Thrace, and to the defence of the Athenian possessions in the Chersonese, in which he is said to have been successful, notwithstanding the appearance of a Theban fleet under Epaminondas; but for some reason not now known he retired from his command. In 358 the cities of Eubœa sent messages to Athens entreating aid against the Thebans, who had despatched a large force into the island. Through the energy of Timotheus, within 5 days an Athenian fleet and army under his command was in Eubœa, and in the course of 30 days the Thebans were forced to evacuate the island under capitulation. In 356, the second year of the social war, Chares, Iphicrates and his son Menestheus, and Timotheus were appointed to the joint command of an Athenian fleet, which first directed its attention to the reduction of Byzantium, whereupon the fleet of the Ohians and their allies raised the siege of Samos and sailed to the Hellespont. The Athenian commanders agreed upon a common plan of action, when a sudden storm arose, which in the judgment of Iphicrates and Timotheus rendered it inadvisable to begin a bat-

tle. Chares thought differently, and calling upon the men to follow him rushed into the fight without his colleagues and was driven back. Hereupon he wrote to Athens accusing his colleagues of corruption and backwardness in not supporting him. A trial of accountability was afterward held at Athens, in which Iphicrates and Timotheus were charged with having received bribes from the Ohians and Rhodians, and with betraying their trust by deserting Chares at a moment when success might have been gained. The former was acquitted, but the latter was found guilty and condemned to pay a fine of 100 talents, although it is not known what caused the difference in the sentences. The fine was the largest ever imposed at Athens, and Timotheus after the trial retired to Chalcis in Eubœa. After his death his son Conon was permitted to compromise the fine by paying 10 talents for repairing the walls of the city. Isocrates, the friend of Timotheus, says that the result of this trial was due to the great unpopularity of the latter in Athens. In the foreign service he had been scrupulously just in his dealings, but his haughtiness had made him extremely unpopular among the political leaders at home. His life was written by Cornelius Nepos.

TIMOTHY (Gr. *Τιμόθεος*, "honored of God"), a disciple of Paul, and his companion in travel and in preaching. He was a native of Derbe or Lystra, and the son of a Greek and a Jewess. To prevent the cavils of the Jews, Paul circumcised him. He was regularly set apart to the office of the ministry by the laying on of the hands of Paul and the presbytery. He journeyed, partly in company with Paul and partly commissioned by him, through Macedonia and Achaia; later he was sent by Paul to Ephesus, whence he accompanied the apostle to Jerusalem, and probably to Rome. In the epistles of Paul written during his captivity at Rome, Timothy is mentioned as being with the apostle. According to ecclesiastical tradition, Timothy was the first bishop of Ephesus, and suffered martyrdom under Domitian.

TIMOTHY, EPISTLES to, two canonical books of the New Testament, addressed by the apostle Paul to his disciple Timothy. They are mentioned by Tertullian, Clement of Alexandria, and Origen, but are not contained in the collection of Marcion. In modern times, Schleiermacher attacked the authenticity of the first epistle, and after him the authenticity of either the first or both epistles has been doubted by Baur, Reuterdahl (now archbishop of Lund), Meyer, De Wette, Ewald, Oederer, and others; against whom it has been defended by Hug, Guericke, Thiersch, Wieseler, Reuss, and others. The first epistle is supposed to have been written about the year 65, and contains instructions respecting the qualifications of various officers in the church, and strong exhortations to fidelity. Purity of conduct and improvement of his spiritual gifts are urged upon

Timothy, and particular directions are given him with regard to various classes of persons. The second epistle was written during the captivity of Paul at Rome, and while he was in expectation of martyrdom. It gives instructions on Christian steadfastness and fidelity (ch. i.); exhorts Timothy to constancy (ch. ii.); warns him against false teachers, invites him to come to Rome, and gives information of many of the companions of Paul (ch. iii. and iv.). The two epistles to Timothy, together with the one to Titus, are comprised under the name pastoral epistles. Recent commentaries on them have been written by Heydenreich (Hadamar, 1826), Hatt (Tübingen, 1881), Mack (Tübingen, 1836), Mathies (Greifswalde, 1840), and Ellicott (London, 1861).

TIMOTHY GRASS (*phleum pratense*, Linn.), a gramineous hay plant, much cultivated in New England and New York, where it is also called Herd's grass, from a Mr. Herd, who, according to Jared Eliot (1750), found it in a swamp near Piscataqua, and in Pennsylvania, where it is known by the first name, derived, it is said, from Mr. Timothy Hanson, who first introduced it either from Europe or from New England, and extensively cultivated it. London says that Mr. Hanson introduced it from America into England, but other authorities call it a native of Europe. In England it is called the meadow cat's tail. Its stem or culm rises to the height of 2 to 4 feet, and is smooth and round; its leaves are flat, rough on their upper surfaces; the sheaths long and striate, smooth; the stipules blunt; the flower spikes long, cylindrical, upright; the flowers consisting of 2 truncated, and awned glumes fringed upon their backs, and of 2 membranaceous pales, distinct styles with white stigmas, and the stamens with purple anthers. Although coarse and hard if allowed to ripen its seed, timothy grass, cut when in blossom or soon after, is greatly relished by stock, and is found to possess a large percentage of nutritive matter. It is well adapted to laying down reclaimed bogs, such as abound in peat, and in instances where 4 tons have been produced per acre the timothy has constituted the bulk of the hay. In drier lands, though its yield is fair, yet it is at a disadvantage because it is tardy in aftergrowth, and needs shading at the roots with clover. Another European species (*P. alpinum*, Linn.) occurs among the White mountains of New Hampshire, and to the northward.

TIMOUR, or **TAMERLANE** (a corruption of Timour Lenk, *i. e.*, Timour the Lame), an oriental conqueror, born in the village of Sebz, in the district of Kesh, about 40 m. S. E. from Samarcand, in 1335, died in Otrar on the Jaxartes, Feb. 19, 1405. He was the son of the chief of the Turkish tribe of Berlas, which inhabited Kesh, and on his mother's side was a direct descendant of Genghis Khan. His birth happened in a period of general anarchy, and of constant and petty wars between the powers which had come into possession of the empire

of Genghis. At 12 years of age he entered military life, and in 1361 became chief of the tribe of Berlas, and succeeded in expelling from the kingdom of Transoxiana the khan of Kashgar, who had invaded it with an army of Getes or Calmucks. In this war he was once plunged into a dungeon, from which he escaped, swimming in his flight the broad stream of the Jihoon; and he also received a wound in the thigh at the siege of the capital of Sistan, which left him permanently lame. He had during these scenes of tumult supported the cause of Hussein, khan of northern Khorassan, and after having driven out the Calmucks he married the sister of that powerful chief. With him he had frequent contentions, being unwilling to endure either an equal or superior, and on one occasion sent him the message that "he who wishes to embrace the bride of royalty must kiss her across the edge of a sharp sword." At last the difference between them broke out into an open war. With a body of horsemen numbering only 250, he surprised and took the city of Nakhshab, defended by a garrison of 12,000, and in 1366 totally defeated his rival near his capital Balkh. Hussein was put to death, and Balkh taken in 1369, after a siege of 8 years. In the same year a general diet was held, and Timour proclaimed khan of Jagatal, Samarcand being chosen as his residence. He now aspired to the dominion of all the countries once under the power of Genghis Khan, and attacked the neighboring princes in detail. The khan of the Getes, ruling the country between the Jaxartes and the Irtysh, was forced to render homage, and in 1379 the khan of Khiva was conquered. He then undertook the reduction of Khorassan, and received the submission of a part of it, but was met with a fierce resistance by Gaiyath-ed-Deen-Pir-Ali, whose capital was Herat. His efforts were all in vain, and the taking of his capital by storm paved the way for the easy conquest of the remainder of the country. All Khorassan was now in his power; but the town of Sebsewar revolted, was stormed, and 2,000 of the inhabitants while still living were placed upon one another, until the whole pile assumed the shape of a tower, and the layers of human beings were then fastened together by mortar. Aspiring now to the conquest of the world, Timour fixed his eyes on Persia, ruled by petty tyrants, who were successively beaten. All Persia was soon in his power, and the country between the Tigris and the Euphrates, from the sources to the mouths of those rivers, submitted to his authority, and the Christian princes of Georgia also became his tributaries. An invasion of Timour's territory by Toctamish, whom he himself had established in the Mongol empire of the north, led to the conquest of western Tartary. The pursuit of his enemy having led the conqueror of the East into the provinces of Russia, he threatened Moscow, marched to the south, and sacked and burned Azof at the mouth of the Don. He now

turned his attention to the conquest of India, at the idea of which his emirs at first revolted. "The rivers!" said they, "and the mountains and deserts! and the soldiers clad in armor! and the elephants, destroyers of men!" But the conqueror was neither to be terrified nor turned aside. The vast army crossed the Indus in 1398 at the passage of Attok, and, after a long march, in which he massacred 100,000 captives, stood before Delhi. A battle was fought in the plain near the city, and the stately capital of Hindostan became the prize of the victors. He penetrated still further into the country, when he was recalled by the news of insurrections in Georgia and Anatolia, and of the designs of Bajazet, sultan of Turkey. His first care was to crush the rebellion in Georgia, and as the Mongol and Ottoman conquests now bordered upon one another, a collision was soon rendered certain. Timour overran Syria, then a dependency of Egypt, and having stormed the revolted city of Bagdad, July 9, 1401, left in the public places of the town a pile of 90,000 slaughtered human beings. At last the two great armies of the sultan and the Mongol conqueror met on July 20, 1403, on the plains of Angora, and the former was totally defeated, and captured in attempting to save himself by flight. The story that Timour placed his royal prisoner in an iron cage is now deemed doubtful, but in spite of the authority of the Persian historians of the times, it is almost certain that Bajazet was treated harshly, and not long afterward he died. Timour's dominions now covered all Asia from the Irtish and Volga to the Persian gulf, and from the Ganges to Damascus and the archipelago. He might have added Europe to his conquests, but he had not a single galley to transport his army over the narrow sea which divides the two continents, nor could he prevail upon either the Turks or the Greeks to furnish him with any means of transportation. Both submitted to pay tribute to the oriental conqueror, however, and he was also gratified with the nominal allegiance of the sultan of Egypt. He now retired to Samarcand, and spent two months in festivities, but did not long remain idle. He had planned an invasion of China, from which the house of Genghis had recently been expelled, and previous to his return from his Ottoman conquests had sent an army beyond the Jaxartes to prepare the way for his own advance. At the head of 200,000 veteran troops he began his march, crossed the Jaxartes on the ice, and had already gone a distance of 800 miles from his capital when he was overtaken by death. His army was disbanded and the invasion of China was given up. He died after a reign of 36 years, all of which was spent in military operations, and left 36 sons and grandsons and 17 granddaughters. A large proportion of his conquests, especially in the northern and western parts of Asia, were lost immediately by his successors, among whom constant dissensions

prevailed. Even his race would have become extinct, had not one of his descendants fled before the Usbeks of the north to accomplish the conquest of Hindostan.—The great authority for the life of Tamerlane is the Persian history of Sheref-ed-Deen-Ali, to whom the journals of his secretaries were intrusted, and whose work has been translated into French by Pétis de la Croix under the title of *Histoire de Timur-Bec, connu sous le nom du grand Tamerlan* (4 vols. 12mo., Paris, 1732). The writings attributed to Timour are only known to exist in Persian, and are of questionable authenticity. The "Institutions," with an English translation and a valuable index, was published at Oxford in 1788 (4to.) by Major Davy and White, the professor of Arabic, and has also been translated into French by Langlès. The "Commentaries" of Timour have been translated from a manuscript of Major Davy by Major Stewart, late professor of oriental languages in the East India company's college, and published by the oriental translation committee of London. These only contain his life from his birth to his 41st year, no version having as yet appeared of that portion containing his last 30 years of war and western conquests. The latest work is a translation of the narrative of Olavijo, envoy of Henry III. of Castile to Timour, by O. R. Markham (Hakluyt society, 1860).

TIN (Lat. *stannum*), a metal resembling silver in color and lustre, though presenting a yellowish tint when the white light reflected from its surface is excluded; symbol, Sn; chemical equivalent, 59; specific gravity, 7.29. It is harder than lead and softer than gold, melts at 442° F., and is not sensibly volatilized at high temperatures, though at a strong red heat it emits white fumes. When very slowly cooled from a melted condition, it becomes crystalline, presenting either rhombic plates or octagonal needles, which are distinctly brought to view by treating the external surface with dilute aqua regia. The surface thus prepared is ornamental, and the French make use of this material (*moire métallique*) for the covers of snuff boxes, &c. The crystalline structure of the metal is the cause of the peculiar cracking sound emitted when a bar of tin is bent backward and forward; this sound is designated by the French *le cri d'étain*, or tin cry. Considerable heat is developed by the friction of the particles of metal upon each other. Tin is very malleable, especially when its temperature is raised to 312°. It is readily rolled or beaten into sheets not more than $\frac{1}{16}$ of an inch thick, and is drawn into fine wire. The metal, however, is deficient in tenacity, a wire of $\frac{1}{16}$ inch diameter sustaining only 84½ lbs. weight. At ordinary temperatures tin is slowly tarnished by exposure to air and moisture, but when melted its surface is soon covered with a film of oxide, and at high temperatures its oxidation takes place so rapidly as to cause ignition, and the metal

burns with a brilliant white light. A current of steam passed over the melted metal produces the same oxidizing effect. The product of combustion is first a pulverulent gray oxide, and then a yellow white powder called putty of tin, which is the binocide, consisting of oxygen 27.2 and tin 100. Tin is violently attacked by nitric acid, and slowly by strong hydrochloric acid heated, while it is not affected by dilute sulphuric acid. It combines with several other metals, and forms with them a variety of useful alloys, as also the amalgam employed for silvering mirrors. (See AMALGAM, BRITANNIA METAL, BRONZE, MIRROR, PEWTER, and SPECULUM.)—Tin was used by the ancient Hebrews, Egyptians, and Greeks, and was an especial object of the Phœnicians in their voyages to the southern coasts of Britain. Although it is questioned whether the *bedil* of Ezek. xxvii. 12, Numb. xxxi. 22, Isaiah i. 25, &c., is correctly rendered by the Greek *κασσίτερος*, and this by the English tin, there is no question but that the bronze vessels and implements of very remote periods, found at Thebes and other parts of Egypt, are in part composed of tin, which metal Wilkinson suggests the Egyptians may have obtained from Spain or India long before the voyages of the Phœnicians into the Atlantic. Tin is frequently named in the Iliad, and appears to have been a metal with which the Greeks were familiar. Homer speaks of it as being employed for the raised work on the exterior of shields, for making greaves, and binding together parts of armor, as also for household and ornamental purposes; and, as remarked by Wilkinson, the Greek word named above, translated tin, "is the same as the Arabic name *kasdeer*, by which the metal is still known in the East. It is also called *kastira* in Sanscrit." Strabo, Diodorus Siculus, Pliny, and other ancient writers describe the commerce carried on by the Phœnicians with certain islands off the coast of Britain, named, on account of the quantity of tin there obtained, the Cassiterides. These islands were doubtless the Scilly islands, S. W. of Cornwall, and may have been visited to receive tin brought to them from the tin region of Cornwall; or the Phœnicians, who carefully concealed the real source of their profitable commerce, may have given them this name to mislead the Romans, who long sought to discover the secret. Interesting papers upon this subject may be found in vols. iii. and iv. of the "Transactions of the Geological Society of Cornwall;" see also "Report on the Geology of Cornwall, Devon, and West Somerset," by Sir Henry de la Beche, p. 522. Spain as well as Cornwall furnished this metal to the Phœnicians; and both countries were to this enterprising race what America at a later period was to the Spaniards. In exchange for valuable metals, the early navigators gave earthenware vessels, oil, salt, various implements of bronze, and other objects easily manufactured by a skilful people,

and possessing much value among the rude natives of the mining regions. It is supposed that the beautiful bronze swords, daggers, and spear heads occasionally found in England in the graves of the ancient Britons, were brought into the country for this purpose by the Phœnicians. In the middle ages Cornish tin was largely used for the bells of churches, and at a later period it was in still greater demand for bronze cannon. The Cornish mines in the reign of King John appear to have been managed principally by Jews. Discoveries are still occasionally made of the ruins of furnaces, which are called Jews' houses; and small blocks of tin of an ancient date are also met with, called Jews' tin. The history of these mines is recorded in the "Survey of Cornwall," by Richard Carew (1602, reprinted 1769); in the "Natural History of Cornwall," by the Rev. Richard Borlase (1758); and in various other English publications. Tin mines were discovered in the district of Meissen and in Bohemia in the 12th or 13th centuries; and in 1250 the low price at which the Germans sold their tin seriously affected the English trade. Spain still yields some tin. Other important European localities of tin at the present time are Altenberg in Saxony; Zinnwald and Schlackenwalde in Bohemia; near Limoges in the department of Haute-Vienne, at Pyriac near Nantes, in Loire-Inférieure, and at Ville-dieu in Morbihan, France; and in Dalecarlia, Sweden. The ore is abundant in the Siberian mining district of Neretchinsk; and in southern Asia, it has been very extensively worked in the island of Banca since the discovery of the mines in 1710. In 1751 there were produced here 370 tons; in 1852, 5,235 tons; and in 1858, 8,745 tons. More ancient mines have also been worked to a considerable extent in the Malay peninsula in the province of Tenasserim; in 1858 they yielded 900 to 1,000 tons. There are others in the N. portion of Burmah, and also in Madagascar. Tin ore is imported into England from Victoria in Australia, where it occurs in broken transparent crystals in the deposit gold mines. As early as 1850, 9 tons 9 cwt. of tin were imported from Australia; in 1854, 8½ tons tin and 52 tons ore; in 1855, 49 tons ore; in 1856, 350 tons ore; and in 1857, 816 tons ore. On the American continent, the ore is found in Brazil, Peru, Chili, and Mexico. Peru supplied very variable quantities, amounting in 1856 to 239 tons tin and 371 tons tin ore and regulus. The tin product of Bolivia has been stated to attain 3,000 tons annually, which is enormous, but the produce is certainly very large. The Mexicans obtained tin from the mines of Tasco, of which they made bronze for cutting instruments of great hardness, and small pieces of tin in shape of a T were used for money. Cortes had bronze cannon made with the tin of Tasco. Tin in Greenland is associated with cryolite. In the United States, a few small crystals of the oxide of tin have been found at Chesterfield and Goshen, Mass.,

and also at Lyme, N. H. At Jackson, N. H., is a vein which has furnished small specimens of the ore, and the metal has been detected in the magnetic iron ores of the highlands of New York and New Jersey, and in some of the auriferous ores of Virginia. In California it is found in such quantity as to encourage the hope of its becoming an important product. Native tin is reported to have been met with in small grayish white grains in the gold washings of Siberia.—The only ore that is worked is the binoxide, SnO_2 , also termed cassiterite, tin stone, &c. It occurs in a variety of forms, as crystallized in right prisms with a square base, also in rolled pieces, called stream tin, among the sand and gravel of superficial deposits, and in concretionary forms, resembling wood in their fibrous structure and concentric layers. The last variety is often known as wood tin. It is in mammillary and kidney-shaped masses, sometimes of a clear brown, and sometimes of a blackish brown color. The concretions are occasionally met with enveloping crystals of quartz in layers, at first parallel to the faces of these crystals, and gradually becoming bent and circular in the external layers. The crystallized oxide of tin has more resemblance to several earthy minerals, as brown idocrase, zircon, &c., than to metallic ores. It is distinguished however by its great weight, its specific gravity being 6.8 to 7.2. Its hardness is 6 to 7. The crystals are usually of brilliant lustre, brown or black, sometimes red, gray, white, or yellow. Tantalum, iron, manganese, and columbic acid have been found in small quantity in specimens of tin ore. Mixed with borax and carbonate of soda, the ore is easily reduced by the blowpipe on charcoal, but alone it is infusible, and in acids it is insoluble.—Several artificial compounds of tin and oxygen are obtained possessing acid properties. Metastannic acid (Sn_2O_3) is a white, crystalline, insoluble mass, obtained by treating metallic tin with nitric acid. After being treated with cold water and then rendered anhydrous by ignition, it constitutes the polishing material known as putty powder, used for giving whiteness and opacity to enamels and for polishing plate. Another oxygen compound is stannic acid (SnO_2, HO), which combined with soda forms a compound largely prepared as a mordant for the use of the dyer and calico printer. It is the basis of what is technically known as tin-prepare liquor. The salt is also used for tinning copper. Three compounds of tin and sulphur are known, of which the bisulphuret is used in the arts as an imitation of bronze under the name of mosaic gold. The protochloride and bichloride of tin are used in dyeing and calico printing. The former has a strong affinity both for chlorine and oxygen, and acts as a powerful reducing agent. When added to a solution of chloride of gold, a purple powder is precipitated, which is an obscure compound of sesquioxide of tin and oxide of gold. It is known as purple of Cassius, and is used for col-

oring porcelain and glass, with which it is incorporated by fusion.—The geology of the tin veins of Cornwall has been noticed in the account of the mines of that region in the article COPPER MINES, vol. v. p. 684. Until the last century it was the tin alone that gave value to these mines; and when in working them yellow copper ores took the place of tin in depth, as was generally the case, the mines were abandoned. When the mines have afterward been worked for the sake of the copper, they have again in many instances been found productive of tin at still greater depths. The modes of occurrence of tin ores are various. Their original source is in veins, in many of the larger of which the ore is obtained in crystalline masses associated with pyritous iron and copper and with ores of antimony and arsenic. The gangue of the veins consists of quartz, fluor spar, heavy spar, and apatite, with which are found tourmaline, mica, topaz, wolfram, and other minerals. It is also found diffused through small veins and threads clustered together and penetrating the rock in certain lines, or disseminated through the mass in proportion sufficient to render it profitable to work, though the particles of ore may be imperceptible to any but an experienced eye. A fourth mode of occurrence is in alluvial deposits, in which lumps are found that have been washed from the larger veins, and present a rolled appearance like nuggets of gold found under the same conditions. These deposits have been worked from the earliest periods of tin mining, and for centuries all the tin of Cornwall was obtained from them exclusively. The ore they produce is known as stream tin, from the application of currents of water employed to separate it from its earthy and stony accompaniments. Some of these alluvial deposits have attained a great depth, even within the historic period. Thus at the Carnon tin stream works, N. of Falmouth, the excavations have been carried to the depth of 50 feet, where the tin pebbles are found overlaid with vegetable accumulations containing human skulls, remains of deer, and trees in the place of their growth. The small flat veins are sometimes very numerous, running between the layers of killas from one large vein to another, and are known as tin floors. When the ore is disseminated in small veins and particles through masses of rock, which is usually the variety of porphyry called in Cornwall elvan, the repository is sometimes worked open to the day like a quarry. The veins with which the rock is charged are often mere threads, and seldom exceed 8 or 9 inches in thickness; and even these are so irregular and interrupted, that their direction or inclination cannot always be determined. This mode of occurrence of ores is called by the Germans a *Stockwerk*. The principal veins of tin are found in three districts, the first and most productive in the S. W. of Cornwall beyond Truro, the second around St. Austell, and the third near Tavis-

took, in Devonshire.—Stream tin, being a pure ore, requires no preparation for the reduction process; but that obtained from the veins, being much mixed with other ores and stony matters, requires to be carefully sorted and dressed. When obtained from lodes which yield copper ore also, the two kinds are separated as well as may be by hand, and the best and purest fragments of tin ore are kept by themselves, and those less rich form another division. The latter are reduced to powder under heavy stamps, large batteries of which are worked in connection with the mines. The pulverized ore is washed away from the stamps by a strong current of water, and in the first vats through which it passes the richer and coarser particles are deposited. The remainder passes on through the dressing apparatus, consisting of buddles, tossing tubs, shaking tables, &c., by which it is separated as completely as possible from its accompanying impurities. The concentrated ores are next roasted in reverberatory furnaces in order to decompose the sulphurets and arseniurets, the fumes from which pass off into a chimney through condensing chambers, in which the arsenious acid is collected. When purified by another sublimation, this is converted into the white arsenic of commerce. The roasting of a charge of 6 to 10 cwt. of ore requires from 12 to 18 hours. The heat is very gradually raised till it reaches a dull redness, and occasionally during the process the door is opened and the charge is raked over the hearth. On its ceasing to exhale white fumes it is withdrawn from the furnace and falls into an arched chamber beneath, where it is allowed to cool. It is then again washed, by which it is easily freed from the chief portion of its impurities. But if much copper is present, the roasted tin ores are commonly placed in a vessel containing dilute sulphuric acid, which dissolves the copper without affecting the oxide of tin, which after washing in pure water is ready for the smelter. The mineral wolfram (a double tungstate of iron and manganese), which accompanies some tin ores, is so nearly of the same specific gravity with the oxide of tin, that they cannot be separated by mechanical means; and it is then necessary to decompose the wolfram by mixing a little carbonate or sulphate of soda with the ore and heating this to redness in a reverberatory furnace. The tungstic acid unites with the soda, forming a soluble compound, which may be removed by water, and after crystallization be employed by the calico printers as a mordant. The smelting of tin ores was conducted by very rude methods even into the 17th century. Remains of old furnaces are occasionally met with in Cornwall and Devon, with remnants of the scoria produced in the operations and of the peat that was used for fuel. As an evidence of the imperfection of the process, samples of the scoria have been found to contain 22.85 per cent. of oxide of tin. Some of the furnaces or hearths were cavities excavated in the

ground, in which the fires were no doubt kept up by a blast. Pit coal was first successfully used in the reign of Queen Anne, and soon after reverberatory furnaces were invented and found to be better adapted than the blast furnaces hitherto in use for reducing the ores. At the present time this kind of furnace is used in Cornwall exclusively for the common class of ores, which are mixed with anthracite dust or other pulverized carbonaceous matter and heated by fires of bituminous coal. Blast furnaces are used only for the best ore or stream tin, and for this only when it is desired to obtain very pure metal. Tin ores are smelted near the mines with fuel brought from Wales, as return freight for vessels which carry copper ores to be reduced in the great smelting establishments at Swansea. Tin smelting in reverberatory furnaces is conducted in establishments termed smelting houses, and the blast furnace operation in what are known as blowing houses. In the former process the charge consists of 20 to 25 cwt. of ore containing from 60 to 65 per cent. of tin, mixed with pulverized anthracite and a small quantity of slaked lime or fluor spar as a flux for combining with the silicious portions of the ore. After the charge has remained in the furnace 6 or 8 hours with the doors closely shut, and subjected to a high heat which has been gradually increased in intensity, a door is opened at the further extremity of the furnace under the escape flue, and the melted matter is worked up with a long paddle in order to determine its condition and separate the metal from the slags. When the reduction appears to be complete, the latter are raked out upon the floor and sorted. About $\frac{1}{4}$ of the whole should be free from metal and requires no further treatment. Another portion may contain 4 or 5 per cent. of tin in small shot, which may be separated by stamping and washing. A third portion, consisting of the scoriae last raked out, is so rich in tin as to be saved for the next melting process. The melted metal is then drawn off through an opening in the side furnace into a cast iron pot, and a new charge is introduced into the furnace. The scoria adhering to the tin soon rises upon its surface and is skimmed off, and the metal is then ladled into rectangular moulds. It still contains so many impurities, as iron, arsenic, copper, and tungsten, together with some oxide of tin, that it is necessary to subject it to further processes of refining. The blocks are laid up together near the fire bridge of the furnace, and gradually brought to the point of fusion. As they melt the tin flows down the hearth and into the outer basin, and an infusible dross of ferruginous matter remains behind. More blocks of tin are charged; and this liquation or sweating operation is continued till about 5 tons of melted metal are collected. The dross is then removed, to be afterward returned to the furnace with the stamped and washed scoriae of former processes. The metal in the pot is

refined by sinking into it green wood held by an iron frame, which causes a violent ebullition with the evolution of gases and aqueous vapor. A scum formed of oxide of tin and other oxides collects upon the surface, and is skimmed off to be returned to the smelting furnace. The boiling with green wood is continued for about 8 hours, and another hour is allowed for the subsidence of the fluid metal. This diminishes in purity from the top down; the upper portion, which is pure metal, is carefully ladled into cast iron moulds and set aside as refined tin; the middle portion produces tin of second quality; while the lowest is so impure, that it is necessary to subject it again to the reduction process. A method called tossing is sometimes employed instead of refining by the introduction of green wood; this consists in keeping the fluid metal in agitation by lifting up portions in a ladle, and letting them fall from a considerable height into the pot, whereby oxidation of the foreign metals is effected, and their collection upon the surface in a scum. The purest variety has been found to contain 99.76 per cent. of tin and 0.24 per cent. of copper; common tin, 98.64 per cent. of tin, 1.16 of copper, and 0.20 of lead; and the poorest, which is only fit to be returned to the furnace, 95 per cent. of tin. About 80 cwt. of coal is consumed for every ton of metallic tin obtained, and the loss of the metal in the process is about 5 per cent. Smelting in a blast furnace, formerly practised to some extent in Cornwall, and generally at the present time in the Erzgebirge in Saxony, involves the consumption of a larger proportion of fuel, and an average loss of 15 per cent. of metal, owing to the oxidizing effects of the blast; but the tin obtained by it, on account of the better quality of both ore and fuel, is much superior to that made by the other method. The old English blast furnaces were only about 6 feet high, and those of the Germans are about 10 feet high. The bottom stone is made much thicker in the back than in the front, so as to present a considerable slope toward the breast of the furnace. Diffused matters continually flow down this surface and under the front wall into a receptacle hollowed out of a mass of granite and lined with a mixture of clay and powdered charcoal. In this the separation of the slags from the metal takes place, and as they float upon the surface they are removed, while the metal itself is occasionally drawn off through a tapping hole in the front of the basin, into a smaller receptacle in which it is refined by thrusting into it a pole of green wood. The slags and different varieties of metal are treated like those obtained by the other smelting process. The tin is cast in moulds of white marble into blocks of different sizes, the largest of which weigh about 8 cwt.; it is from these that the commercial term block tin is derived. Another form in which the metal is sent to market is termed grain tin; this is produced by heating the blocks in a bath of melted tin, and when the metal has

assumed a crystalline structure it is taken out and shattered by a blow into long crystalline fibrous columns.—Tin is used in a pure state for a few purposes only; sometimes for the bearings of wheels and also for dyers' kettles, but more particularly in the condition of foil for a variety of purposes. The metal is beaten into very large sheets, some of which measure 200 by 100 inches, which is as thick as a common card. These are cut up and reduced to small sheets not exceeding $\frac{1}{16}$ of an inch in thickness. The process is, to first reduce it between rolls, and then hammer it one sheet at a time upon a large iron surface or anvil. The hammers employed for this purpose are provided with very long handles, and are worked with great skill and caution to avoid making holes in the sheet. What is known as the white Dutch metal is much thinner than the common sheets, mentioned above. Tin foil is used for coating Leyden jars, and for making the amalgam used for electrical machines, and more largely for enclosing small packages of tobacco and spices, covering tops of champagne bottles, &c., to exclude the air. The only use of the large sheets is for silvering looking-glasses. (See MIRROR.) Tubes of pure tin are used for gas fittings, and have been recently applied to the construction of cheap vessels for containing the liquid colors used by artists, as also other solid and fluid substances required to be hermetically sealed and at the same time admitting the abstraction of small quantities. Tin wire is soft, moderately tenacious, completely inelastic, and admits of being bent and unbent many times without breaking.—The most important application of tin is for the coating of plates of sheet iron, producing what is known as tin plates or sheet tin, or, as called in Scotland, white iron. The Romans understood the art of coating copper with tin, and their *vasa stannea* are supposed to have been made of the former metal and overlaid with tin. The disagreeable and injurious qualities of the copper were thus obviated, while the advantages of its strength and facility of shaping were retained. The coating was easily effected by dipping the copper vessel, when thoroughly clean, into melted tin;* but iron did not so readily take this coating, nor was it produced in thin sheets, and the method of preparing these and cleaning them for this purpose appears not to have been discovered until the 17th century. It is supposed to have been first practised in Bohemia, and was introduced into Saxony in 1620, and into England in 1670. The first successful works in operation in England were established at Pontypool about the

* The method of tinning copper now practised is to clean the heated surface of the metal by rubbing it with sal ammoniac, then sprinkling resin over it to prevent oxidation, and pouring on melted tin, which is spread over the surface with trow, the workman keeping the metals at a high temperature. The addition to the tin of $\frac{1}{4}$ lead renders the operation easier by the greater fusibility of the alloy; but the introduction of lead may be objectionable from the danger of poisonous effects, similar to those it is desired to guard against by covering the copper with a harmless metal.

year 1720. The method of rolling iron invented by John Payne in 1728 at once furnished the means of producing plates adapted for this operation; and these are now carried to a high degree of perfection through successive improvements in the manufacture of iron, brought about in great measure in consequence of the need of a superior quality of sheet iron for this use. The best of pig iron, and that specially adapted for making the strongest and most ductile wrought iron, is selected, and is converted in a chafery or hollow fire and a finery in which charcoal is employed as fuel, and which causes the plates to be known as charcoal tin plates. A light spongy coke is also used, made from very pure bituminous coal, and purified while hot by the action of steam, which is found to answer an equally good purpose with charcoal. When converted into blooms, these are reheated and worked over several times, and drawn down into bars and plates; the latter are repeatedly doubled and passed through rolls, trimmed at the edges, reheated, and again rolled and doubled, till sometimes 16 distinct thicknesses are passed together between the rollers as one. Care is taken that they are not heated so high as to be welded together, and they are partially separated from time to time. When sufficiently rolled, the rough edges of the pile are cut off by a pair of shears, and the plates are divided across to reduce them to the required dimensions. They are then taken apart, the imperfect ones are rejected, and the good ones, called black plates, are immersed for 15 or 20 minutes in dilute sulphuric acid, which removes the scale of oxide, and leaves them with a clean dull gray surface. They are then rubbed with sand and water and washed, after which, being of a brittle texture, they require to be strengthened by annealing. Large numbers of them are placed in cast iron boxes, the covers of which are carefully luted down to prevent air entering, and the boxes are placed in a sort of reverberatory furnace, in which they are kept at a cherry red heat for 12 hours. They are then taken out, and the covers being removed the plates are examined, and those which are injured and adhere to one another through excessive heat are rejected; some may also be injured by partial oxidation, owing to penetration of air into the boxes. Those in good condition present a purplish surface derived from a thin external film of oxide. They are now in a cold state passed several times through very hard and smooth polishing rolls, thus acquiring a surface of extreme smoothness and lustre, but somewhat mottled from superficial oxidation. The rolling renders them brittle, so that they require annealing again, which is conducted at a milder temperature than before, and in about half the time. After this the plates are again sorted, and the good ones are again pickled for 10 minutes in sulphuric acid more diluted than before, and rubbed with sand and water. They are now perfectly clean, and ready to be tinned. Though

by being exposed to the air a few moments they become rusty, they may be kept as long as desired immersed in pure water without risk of injury. With great care to keep them perfectly clean, they are removed to the tinning apparatus or "stow," which consists of a series of rectangular pots arranged in a long stack, each one over a separate fire to keep the materials it contains in a fluid state. The first of these, called the tinman's pot, about 2 feet long, 15 inches wide, and 20 inches deep, contains melted grease in which the plates are immersed and left till all the moisture upon them has evaporated. The second, called the tin pot, contains melted tin covered with a layer of grease; and into this the plates are next passed and left for about 20 minutes. The third, called the washing or dipping pot, consists of two compartments, each containing melted tin, the second of the purest quality, which as it becomes alloyed with iron is removed into the first compartment, and thence back to the second or tin pot. The plates are passed from the tin pot into the molten tin of the first compartment, and are left long enough to complete the alloy and to separate any superfluous tin adhering to the surface. They are then taken out one by one, laid upon a smooth portion of the stack, and after being wiped with a brush of hemp are dipped quickly into the pure tin of the second compartment, and immediately afterward into the fourth or grease pot, which is filled with melted grease carefully maintained at the proper temperature. The object of this is to allow any superfluous tin to run off, and more especially, by maintaining a uniform temperature, to prevent a more rapid cooling of the surface, which would cause the alloy to crack. After immersion for 10 minutes the plates are removed to the fifth pot, containing tallow heated to a lower temperature. The plates are thus annealed, and all that remains is to remove an edging of tin which usually forms around them. This is effected by dipping them into the last and smallest pot of the series, which contains melted cast iron over a bottom of tin $\frac{1}{4}$ of an inch deep. When immersed in this, the edging melts and is removed by a quick blow on the plate with a stick. To finish the plates for the market, they are cleaned of grease and dirt by rubbing them with bran and then with sheepskin. Defective plates are picked out and rejected, and the others are packed in boxes which are branded on the outside with the marks indicating the size and quality of the plates.—Iron is sometimes first coated with zinc, and when the surface has been cleaned by washing in acid or otherwise, it is tinned by dipping it into the fused metal, the surface of which is covered with fatty or oily matters. Rolled sheet or plate zinc when thoroughly cleaned is readily tinned by dipping it into the melted metal when heated to about its temperature. The zinc should not be left so long as to become alloyed with the tin beyond the mere surface.

After being coated it may be rolled out, and if the tin is deficient more may be added by another dipping. Lead and its alloys may also be coated with tin by a similar process.—The production of the mines of Cornwall and Devonshire, from the year 1750 to 1800, varied from 1,400 to 2,000 tons per annum. It has since been as follows for the years named:

Years.	Tons.	Years.	Tons.	Years.	Tons.
1800.....	2,592	1885.....	4,858	1850.....	6,789
1805.....	2,785	1880.....	4,444	1855.....	6,000
1810.....	2,066	1885.....	4,298	1860.....	6,177
1815.....	2,941	1848.....	6,618	1857.....	6,582
1820.....	2,990	1849.....	6,952	1858.....	6,920

The value of the tin per ton ranges in different years from £112 to £180, and the price has increased of late years.—The tin mines of Banca are next in importance to those of Cornwall. These are deposit mines, and are worked by excavations, carried down through beds of sand, clay, and gravel, sometimes to the depth of 20 or 25 feet. Soon after the discovery of the ore in the early part of the last century, the island was overrun by Chinese miners and adventurers, and the most favorable spots near streams of water were soon worked out. Between 1750 and 1775 it is supposed that they produced annually about 60,000 piculs or 120,000 ingots, and after 1780 not more than half this amount; and of late years the product has still further decreased. The smelting operation is conducted only once or twice a year, usually between February and April, in blast furnaces described as 10 feet long, 4 feet high, and 4 feet wide. The fireplace occupies a depression 8 feet deep in the middle, with a basin-shaped receptacle beneath it for the refined metal. The bellows is a wooden cylinder formed out of a single tree, and charcoal is employed as the fuel. On account of the heat of the weather the fires are run only at night, during which from 44 to 45 ingots are cast in sand moulds. The mines are in a granitic region, an account of which by Thomas Horsfield, M.D., is published in the "Journal of the Indian Archipelago and Eastern Asia," vol. iii., No. 7 (1848); see also "American Journal of Science," second series, vol. vii., p. 86. Tin is also found throughout the greater part of the Malay peninsula, and upon many of the islands between it and Java. The product of the mines is collected chiefly at Batavia, from which the exportation under the Dutch government amounts to about 2,000 tons annually. The quality of the tin of Malacca and of the islands differs very much according to the locality of its production, owing, as is supposed, to the difference of skill in the smelting process. The operations at Banca are said to be carried on upon a larger scale and more skilfully than at any other place in this region, and the metal from this island is consequently more highly valued. At Singapore, which is an important mart for this product, the price of tin has fluctuated of late years from \$14 to \$20 per picul, equal to about \$11.75 to \$16.75 per cwt. At

the average of these prices the annual value of the whole Malay tin will be about \$1,200,000.—The following table presents the value of tin and manufactures of tin imported into the United States for the years named:

Character.	1857.	1858.	1859.	1860.
Bars, blocks, and pigs.....	\$1,023,210	\$1,292,707	\$1,089,781	\$1,120,599
Plates and sheets.....	4,789,588	3,842,968	5,281,147	4,081,656
Foil.....	\$1,426	25,317	24,401	57,006
Manufactures not specified	\$1,222	\$7,675	23,628	24,929
Total.....	\$5,566,006	\$5,168,667	\$6,425,967	\$5,883,197

TINAMOU, a name applied to the *tinamides*, a family of rasorial or gallinaceous birds peculiar to South America. The bill is moderate, rather straight, flattened, the base covered by a membrane, and the tip suddenly hooked; wings short and concave; tail short or wanting; tarsi rather long, scaled in front, and without spurs; toes long, with stout blunt claws, the hind one sometimes wanting. They live in the fields on the borders of woods, are low and heavy fliers, but rapid runners, and feed on grains, fruits, and insects, often visiting newly sown spots to pick up the seeds; they lay about a dozen eggs, on the ground in tufts of grass, and the young when hatched soon disperse; such is their indisposition to fly, that when pursued they endeavor to hide in the bushes, and are often caught by a noose on the end of a stick; their flesh is exceedingly good; they vary from 18 to 6 inches in length, and are usually of a reddish or gray brown. In the genus *tinamus* (Lath.; *crypturus*, Illig.), the bill is shorter than the head, the upper mandible the longest, and the nostrils in the middle; first quill short, 4th and 5th longest; hind toe small and elevated. The great tinamou (*T. brasiliensis*, Lath.) is about 15 inches long, of a deep olive color, slightly and narrowly banded with black, with crown red and secondaries red and black; pale reddish ash below; it is found in Guiana and Brazil, resembling in size, habits, colors, and quality of flesh, the partridges of the old world; though gentle and timid, it is said not to be capable of domestication. The males have a trembling plaintive whistle to warn of danger or attract the females; they live in couples during breeding time, at other seasons in small flocks; they seek their food in the morning and evening, scratching on the ground and covering themselves with dust like the common fowl. The nest is made on the ground in a slight hollow, covered with dry grasses; they lay twice a year; the young follow the parent as soon as hatched; they are said to roost on trees 2 or 3 feet from the ground. In the genus *rhynchotus* (Spix) the bill is longer than the head, slightly arched, the upper not overlapping the under mandible, and the tail is not visible on account of the numerous long soft coverts. The rufescent tinamou (*R. rufescens*, Wagl.) is 15½ inches long, ashy red above,

anded with white and black; yellowish red elow waved with brown; sides ashy. It inhabits the borders of the lakes and the swampy bickets of Paraguay in small troops; the eggs re 7, of a violet color; it is killed for its flesh, which is delicately white when cooked. In the enus *tinamotis* (Vigors) the bill is shorter than he head, the tail concealed by the pendulous overts, the tarsi short and robust, and the toes hort and thick, with claws broad and very onvex above, and the hind toe wanting. There are only 3 or 4 species, inhabiting high, ry, and desert places, generally at some distance from fresh water, and feeding on seeds nd small fruits; in some points these birds ome near the bustards.

TINCTURE, in pharmacy, a solution, commonly colored (whence the name), of medicinal substances, usually in proof or diluted spirit, and with the same mixed with ammonia. This and ether are also used alone as the olvents, and preparations in which these are mployed are known respectively as ammoniated and ethereal tinctures. Some highly colored acid solutions, as the preparations of chloride of iron, &c., are also called tinctures. This class of medicinal preparations are included under the more general name of extracts, and the methods of producing them ave been described under that head. Compound tinctures are those containing two or aore medicinal principles.

TINDAL, MATTHEW, an English theological nd political writer, born at Beer-Ferris, Devonshire, about 1657, died Aug. 16, 1738. The on of a clergyman, he was educated at Lincoln nd Exeter colleges, Oxford, took the degree of achelor in 1676, and was elected to a fellowship at All Souls, which he retained through ife. He was created LL.D. in 1685, and soon fter became a Roman Catholic. As he returned to the church of England just before he revolution of 1688, he was charged with hanging his creed according to his political interests. His own explanation was that he went o the university without religious opinions, dopted Catholicism without examination, and abandoned it upon reflection. After the revolution, of which he was a zealous partisan, he became an advocate, sat as judge in the court f delegates, and received a pension from the crown of £300. He had already produced several pamphlets in favor of the government, when in 1706 he published a volume entitled 'The Rights of the Christian Church asserted, against the Romish and all other Priests that claim an independent Power over it.' It was an elaborate attack on high church principles, nd involved him in a controversy with William Wotton, Dr. Hickeys, and others, which continued several years. He published two defences of it, and in 1709 reprinted them, and also two other essays on the law of nations and he liberty of the press. In 1710 he attacked he party of Dr. Sacheverell in a pamphlet entitled "New High Church turned Old Presby-

terian;" but the house of commons on one day condemned Sacheverell's sermons, and on the next ordered Tindal's "Rights of the Christian Church" and the second edition of his "Defences" to be burned. This was the occasion of three more pamphlets from him, followed by many others in succeeding years on the current political questions. In a personal controversy between him and Walpole, after the resignation of the latter in 1717, several pamphlets were written on each side; but he was afterward an active defender of the ministry of Walpole. In 1738 he published two polemic "Addresses," in reply to pastoral letters of the bishop of London, Dr. Gibson. His most important work, "Christianity as Old as the Creation, or the Gospel a Republication of the Religion of Nature," appeared in 1730. It expressly denies that Christianity contains any truth which the human reason might not have discovered for itself, and by implication denies that it is a special revelation. "Under pretence," says Warburton, "of advancing the antiquity of Christianity, he labored to undermine its original." Among the many answers which it called forth were treatises by Waterland, James Foster, Conybeare, Leland, and Ohapman. The last writings of Tindal were in its defence. He left a second volume of "Christianity as Old as the Creation," only the preface to which has been published.

TINDALE, WILLIAM. See TYNDALE.

TING-HAI, a town of China, province of Che-kiang, capital of the island of Ohu-san, situated on the S. side of the island, in lat. 30° N., long. 122° 6' E.; pop. 35,000. It stands in the valley of Yung-tung, about 900 yards from the beach, with which it is connected by a causeway and two canals about 4 feet deep. The city is strongly walled and fortified, nearly encircled by a canal 33 feet wide and 8 feet deep, and several canals traverse it in different directions. The streets are narrow and paved with granite, with sewers underneath. The chief public edifices are two temples dedicated to ancestors and to the guardian idol of the city. The suburb of Tau-tan extends along the shore and forms one long street, at the E. end of which is a hill surmounted by a temple. There are some manufactures, and cabinet making and carving are carried on. The harbor is one of the best on the coasts of China, and is accessible by 3 or 4 passages. Some trade exists. The city was bombarded and captured by the English in July, 1841, and again in October of the same year.

TINTORETTO, LI, an Italian painter, born in Venice in 1512, died there in 1594. He was the son of a dyer, and from the occupation of his father derived the name by which he is commonly known, his true name being Jacopo Robusti. His early instruction was acquired in the school of Titian, where, however, according to the common account, he remained but a short time in consequence of the jealousy or dissatisfaction of his master,

who dismissed him with the remark that "he would never be any thing but a dauber." Undiscouraged by this harsh treatment, he commenced a rigorous course of self-instruction, and placed over the apartment in which he pursued his studies the inscription, *Il disegno di Michel Agnolo; il colorito di Tiziano* ("The drawing of Michel Angelo and the coloring of Titian"), as expressive of the principles he intended to follow. He was, however, of too vigorous and original a genius to rest contented with the reputation of a successful follower of either of these masters, but aspired to become the founder of a school, which should supply whatever was deficient in their styles. Beside copying the works of both, he was in the habit of designing from plaster casts by lamplight in order to acquire skill in the use of chiaroscuro, the result of which practice may be seen in the union of strong shadows with the rich Venetian coloring which gives so peculiar a character to his pictures. In like manner he improved himself in the science of perspective and foreshortening by suspending his models in various positions from the ceiling by means of cords. He soon rose into great reputation among the Venetians, ranking with Paul Veronese as one of the last of the great painters of the golden age of Italian art; and in his best period his quickness of invention and the facility and rapidity of his execution were unequalled perhaps by any painter. He sought rather than avoided difficulties, and is even said to have frequently dispensed with any preliminary design or sketch, and to have composed his picture as he went along, indicating with a few patches of color the liveliest forms and expressions, and crowding his canvas with a multitude of figures in every attitude that a fertile but reckless imagination could conceive. His performances are necessarily unequal, the grossest faults being frequently found in close proximity with the highest beauty; whence the remark of Annibale Carracci, that Tintoretto was sometimes equal to Titian, at others inferior to himself; and it may be said of his works generally, that, despite their grandeur, dramatic vivacity, brilliancy of coloring, and luxuriant invention, they are deficient in artistic arrangement and in the elevation which properly belongs to history. Consequently, among the amazing number of pictures which he produced, his portraits, giving less scope to the impetuosity of his genius, stand preëminent. He also exhibited the characteristic excellence of his school in landscape painting, the intensity of his imagination being such, according to Ruskin, that "there is not the commonest object to which he will not attach a range of suggestiveness almost limitless, nor a stone, leaf, or shadow, nor any thing so small, but he will give it meaning and oracular voice." History however was the department in which he chiefly delighted, and in which the characteristic excellences and defects of his style are

most apparent; and upon his great historical pictures in Venice his reputation mainly rests. Elsewhere, it has been observed, most of his works exhibit only his infirmities. His masterpieces are undoubtedly the two immense compositions representing St. Mark rescuing a tortured slave from the hands of the heathen, and the "Crucifixion," both painted in his best period; the former, perhaps the finest picture in the world for action, is now in the academy of Venice, and the latter, described by Ruskin as "beyond all analysis and above all praise," in the Scuola di S. Rocco, where are also 61 other large compositions by Tintoretto, each containing many figures of the size of life. The doge's palace is almost equally rich in his works, and contains, among other remarkable pieces, a representation of paradise 84½ feet long and 84 feet high, painted, like almost every thing he produced, in oil. Nothing else on so vast a scale was probably ever painted on canvas. His frescoes are comparatively few. In the latter part of his life he degenerated into a corrupt style, chiefly remarkable for coarseness of invention and a slovenly mechanical execution, of which his "Last Judgment" and "Worshipping of the Golden Calf" in the church of Sta. Maria dell' Orto, are melancholy examples. The rapidity of invention and execution which gained him the name of *Il furioso Tintoretto*, and which Sebastian del Piombo well illustrated by saying that Tintoretto could do as much in two days as he could do in two years, seems never to have deserted him; and in the maturity of his powers he wrought so fast and at so low a price, that few of the contemporary painters of Venice could get employment. Many of his works were bestowed gratuitously upon convents, and for others he received barely sufficient to pay for the materials. Tintoretto has found an enthusiastic panegyrist in Ruskin, who has devoted considerable space to the description of his works. See "Stones of Venice," vol. iii. pp. 324-353.

TIOGA. I. A S. co. of N. Y., bordering on Penn., and intersected by the North branch of the Susquehanna river; area, 480 sq. m.; pop. in 1860, 28,789. The surface is very hilly and the soil generally fertile. The productions in 1855 were 260,074 bushels of Indian corn, 452,978 of oats, 21,293 of wheat, 25,884 of rye, 91,402 of buckwheat, 150,518 of potatoes, 169,188 of apples, 88,401 tons of hay, 1,365,783 lbs. of butter, and 80,144 of wool. There were 2 furnaces, 17 grist mills, 146 saw mills, 12 tanneries, 45 churches, and 4 newspapers, and in 1859 10,875 pupils attending public schools. The North branch is navigable in this county, and immense quantities of timber are annually floated to market. It is intersected by the Erie and the Cayuga and Susquehanna railroads. Capital, Owego. II. A N. co. of Penn., bordering on N. Y., and drained by the Tioga river and its affluents; area, about 1,100 sq. m.; pop. in 1860, 81,045. The surface is hilly and heavily timbered, and the soil better adapt-

ed to grazing than tillage. The productions in 1850 were 141,896 bushels of wheat, 147,140 of Indian corn, 800,017 of oats, 158,289 of potatoes, 87,614 tons of hay, 724,281 lbs. of butter, and 202,851 of maple sugar. There were 18 grist mills, 102 saw mills, 2 iron founderies, 1 furnace, 8 woollen factories, 12 tanneries, 22 churches, 4 newspapers, and in 1860, 9,438 pupils attending public schools. Iron ore is found, and bituminous coal is abundant, of which large quantities are transported to Buffalo, N. Y., by the Corning and Blossburg railroad. Capital, Wellsborough.

TIPPAH, a N. co. of Miss., bordering on Tenn., drained by the Hatchie, Wolf, and Talahatchie rivers and Tippah creek; area, 1,050 sq. m.; pop. in 1860, 22,550, of whom 6,331 were slaves. The surface is undulating and the soil fertile. The productions in 1850 were 365,131 bushels of Indian corn, 83,440 of oats, 125,675 of sweet potatoes, and 12,098 bales of cotton. There were 80 churches, and 202 pupils attending public schools. Capital, Ripley.

TIPPECANOE, a river of Indiana, which rises in a lake of the same name in Kosciusko co., and flows in a general S. W. direction into the Wabash river 9 m. above Lafayette, Tippecanoe co. Its length is about 200 m. It is famous for the battle fought on its banks, Nov. 5, 1811, in which the Americans under Gen. Harrison defeated the Indians under Tecumseh's brother the prophet.

TIPPECANOE, a W. co. of Indiana, intersected by the Wabash river, and drained by the Tippecanoe river and several creeks; area, 600 sq. m.; pop. in 1860, 25,765. The surface is generally level, and the soil a rich black loam. The productions in 1850 were 1,833,311 bushels of Indian corn, 68,259 of wheat, 95,038 of oats, and 6,871 tons of hay. There were 32 churches, 5 newspapers, and 2,042 pupils attending public schools. It is intersected by the Toledo and Wabash, the New Albany and Salem, and the Lafayette and Indianapolis railroads, and by the Wabash and Erie canal. Capital, Lafayette.

TIPPERARY, a county in the province of Munster, Ireland, bounded by the counties of Galway, King's, Queen's, Kilkenny, Waterford, Cork, Limerick, and Clare; area, 1,659 sq. m.; pop. in 1861, 247,496. The chief towns are Donnel, Carrick-on-Suir, Nenagh, and Tipperary, the capital. In the N. part a range of mountains extends completely across from the Shannon to King's county, and there are several groups in other parts of the county, the highest of which does not exceed 3,000 feet above the sea. The principal rivers are the Shannon, which flows along the W. boundary, and the Suir on the S. With the exception of the portion of Lough Derg which is in Tipperary, all the other lakes are small. The soil of the level country is a rich loam of great fertility. There are large numbers of horned cattle in Tipperary, and butter is extensively made and exported. Coal, copper, and lead are found;

and slates are extensively worked. The county returns two members to parliament.

TIPPOO SULTAN, or TIPPOO SAHIB, the last independent sovereign of Mysore, born in 1749, killed at Seringapatam, May 4, 1799. The son of Hyder Ali, he was first known by the appellation of Feth Ali Khan, was carefully educated, distinguished himself by great personal bravery and military ability as a commander in the war against the English, and succeeded his father, Dec. 7, 1782. He at once gave a new impulse to the war, took Bednore and other cities, and concluded a peace, March 11, 1784, on advantageous terms to himself. He now assumed the title of sultan, and even the superior one of padishah, although he was but a nabob or lieutenant of the Great Mogul, Shah Allum; and his court, in point of magnificence and splendor, outshone that of any other oriental prince. He meanwhile unsuccessfully courted an alliance with France, 1787-'8, and subdued the Nairs of Malabar, carrying off from that province, it is said, 70,000 Christians, and forcing 100,000 Hindoos to become Mohammedans. Under a flimsy pretext, in April, 1790, he broke the treaty with the English by invading the territory of their ally, the rajah of Travancore. The English in turn invaded Mysore, took several of his strongholds, were joined by the Mahrattas and the subahdar of the Deccan, and, under Cornwallis and Abercromby, besieged him in Seringapatam, his capital. He was now forced to sue for peace, which was concluded, Feb. 24, 1792, Tippoo agreeing to pay within a year 38,000,000 rupees, to give up to the allies nearly half of his dominions, and to deliver two of his sons as hostages. Burning with a desire for revenge, he tried to arouse several Indian princes against his conquerors, entered into secret negotiations with the French governor of Mauritius, and even sent ambassadors to Gen. Bonaparte, who had landed in Egypt, meanwhile increasing the number and efficiency of his troops, enlisting foreign officers, and making every preparation for a renewal of hostilities. The marquis of Wellesley, then governor-general of India, discovering his intrigues and ultimate designs, ordered him to dismiss his French auxiliaries and desist from arming his subjects, and on his refusal gave orders for the invasion of Mysore, Feb. 8, 1799. Two English armies, under Generals Stuart and Harris, advanced, and defeated the Mysoreans in two encounters, at Sidasair and Malaveli; and the sultan himself was obliged to take refuge in Seringapatam. That city was stormed by the army under Gen. Harris, and Tippoo himself was killed while fighting on the ramparts. The conquerors gave up a part of his dominions to their allies, assigned to his family the stronghold of Vellore in the presidency of Madras as their residence, with an annual income of 720,000 rupees, and nominally placed the government in the hands of a native prince, though it was actually vested in the British residents at Mysore.

TIPTON. I. A central co. of Ind., drained by Cicero and Buck creeks; area, 280 sq. m.; pop. in 1860, 8,171. The surface is level and the soil fertile. The productions in 1850 were 151,961 bushels of Indian corn, 8,487 of wheat, 7,715 of oats, and 918 tons of hay. There were 9 or 10 churches, and 264 pupils attending public schools. It is intersected by the Peru and Indianapolis railroad. Capital, Tipton. II. A W. co. of Tenn., bordering on the Mississippi river, and bounded N. by the Hatchie; area, 370 sq. m.; pop. in 1860, 10,704, of whom 5,268 were slaves. It has a level surface and fertile soil. The productions in 1850 were 439,785 bushels of Indian corn, 43,429 of potatoes, 6,611 bales of cotton, and 84,756 lbs. of butter. There were 11 churches, and 295 pupils attending public schools. Its S. E. corner is intersected by the Memphis and Ohio railroad. Capital, Covington.

TIRABOSCHI, GIROLAMO, an Italian literary historian, born in Bergamo, Dec. 28, 1781, died in Modena, June 8, 1794. He was educated in the Jesuit college of Monza, became a member of that order, and about 1766 was appointed professor of rhetoric in the university of Milan. In 1770 he was made librarian of the duke of Modena, and employed the facilities thus afforded him in preparing his great work, *Storia della letteratura Italiana* (18 vols., Modena, 1772-'82; best edition, 16 vols., Milan, 1822-'6), which comprises the literary history of Italy from the earliest times down to the 17th century. As a reward for his labors he was made by the duke of Modena a knight and a member of his council in 1780. Tiraboschi was also the author of many other literary, historical, and biographical works.

TIRESIAS, the great soothsayer of Greek legendary history, born in Thebes. He was the son of Eueres and Ohariclo, and was fabled to have lived through 9 generations of men, but was blind from his 7th year. His loss of sight was ascribed by one account to the fact that he disclosed to mortals what they should not know; by another, to his having seen Minerva bathing, who thereupon blinded him by sprinkling water upon his face. When Ohariclo complained of the severity of the punishment, the goddess, unable to restore his sight, gave him a staff by which he could safely guide his steps, and the ability to comprehend the voice of birds and thus know futurity. In the mythic history of Greece Tiresias appears in events widely separated in time and place, and even in the lower world he was represented as still retaining his prophetic power. His oracle was at Orophomenus.

TIRYNS, one of the oldest cities of Greece, situated in Argolis, 2 m. from Nauplia. Its walls, which were popularly attributed to the Cyclops, are the finest existing specimens of the military architecture of the heroic age of Greece. Pausanias said that these were no less worthy of admiration than the pyramids of Egypt, and were constructed of stones so

large that a yoke of oxen could not stir the least of them, the spaces between them being filled up with smaller stones. The ruins at present occupy the lowest hill of several which rise out of the plain, and the entire circuit of the walls enclosing the citadel is still preserved to some extent, being from 20 to 25 feet wide and $\frac{1}{2}$ of a mile in circumference. On the E. side of the hill are two towers, and the S. E. part of the wall has a remarkable covered gallery 36 feet in length and 5 feet in breadth. The origin of Tiryns belongs to the mythical period, and in 468 B. C. it was entirely destroyed by the Argives, so that no trace of the city now remains except the fortifications. It is now called Tirynthus. It was famed in Greek legendary history as the birthplace, according to some accounts, of Hercules, and the royal seat of Perseus.

TISCHBEIN, JOHANN HEINRICH, a German painter, born at Haina, near Frankenberg, Oct. 3, 1722, died in Cassel, Aug. 22, 1789. Having studied several years under Vanloo in Paris, and subsequently practised his art in Italy, he settled in 1752 at Cassel. He was highly esteemed as a painter of history and mythology. His works are numerous in Germany.—JOHANN HEINRICH WILHELM, a German painter, nephew of the preceding, born at Haina, Feb. 15, 1751, died at Eutin, Oldenburg, July 26, 1829. After gaining some local reputation as a painter of history and landscape, he went in 1781 to Italy, resided 6 years in Rome, and then settled in Naples, where he was appointed director of the academy and rose to the head of his profession. At the breaking out of the Neapolitan revolution in 1799 he returned to Germany. He painted mythological subjects, and excelled in drawing animals; but he is chiefly known at the present day by three elaborate illustrated works: *Têtes des différents animaux dessinées d'après nature* (3 vols. fol., Naples, 1796); "A Collection of Ancient Vases, &c., in the possession of Sir William Hamilton" (4 vols. fol., Naples, 1790), the plates of which, 214 in number, were engraved from Tischbein's designs; and "Illustrations of Homer from Antiques, with Explanations by Heyne" (fol., Göttingen, 1801-'4).

TISCHENDORF, LOBEGOTT FRIEDRICH KONSTANTIN, a German theologian, born at Lengenfeld, Saxony, Jan. 18, 1815. He studied philosophy and theology at the university of Leipzig from 1834 to 1838, and in 1840 was aided by the government of Saxony in making a literary journey through England, France, and Holland, for the purpose of collating the ancient manuscripts of the original text of the Greek Testament, with a view to preparing a thoroughly revised critical edition. In 1843 and 1844 he visited Switzerland, southern France, Italy, Malta, Egypt, Libya, Palestine, Syria, Asia Minor, Constantinople, and Greece, and on his return thoroughly searched the libraries of Vienna and Munich. An important result of this journey (which he described in the work

Reise in den Orient, 2 vols., Leipzig, 1845-'6), beside the information obtained on the libraries of the eastern countries, was a large and most valuable collection of ancient Greek, Syriac, Coptic, Arabic, Georgian, Ethiopian, and Druse manuscripts. A facsimile of a Greek manuscript of the Old Testament, which Tischendorf considered the most ancient manuscript on parchment in Europe, was published at Leipzig in 1846. In 1845 Tischendorf was appointed extraordinary, and in 1850 ordinary professor of theology at Leipzig. In 1849 he made another journey through France and England, and in 1853 in the East, visiting especially Egypt and Mount Sinai, and bringing home another collection of valuable Greek, Arabic, Syriac, and Coptic manuscripts. Beside that above mentioned, he has published a number of old Greek manuscripts of the New Testament, as *Codex Ephraemi* (Leipzig, 1843 and 1845); *Monumenta Sacra Inedita* (1846); *Evangelium Palatinum Ineditum* (1847); *Codex Amiatinus* (1850 and 1854); *Codex Olaromontanus* (1852); and *Fragmenta Sacra Palimpsesta* (1854); and also several editions of the Greek Testament, embodying the results of his critical researches. His critical edition of the Septuagint was published in 1850. He has also devoted much attention to the literature of the Apocrypha, and published extensively on that subject. In 1858 and 1859 he made another literary journey in the East at the expense of the Russian government, and in the convent of St. Catharine at Mount Sinai found a manuscript on vellum, containing, beside many parts of the Old Testament, the Epistle to Barnabas, and the Pastor of Hermas, the entire New Testament, being among all the manuscripts of the New Testament extant from the 4th to the 9th century the only complete one. Tischendorf considers this newly found manuscript, which he calls *Codex Sinaiticus*, more important than any other heretofore known. Its publication has been announced for 1862.

TISHEMINGO, a N. E. co. of Miss., bordering on Tenn. and Ala., bounded N. E. by the Tennessee river, and drained by the Tusculmbia and affluents of the Tennessee and Tombigbee rivers; area, 1,400 sq. m.; pop. in 1860, 24,149, of whom 4,961 were slaves. The surface is hilly and the soil fertile. The productions in 1850 were 526,769 bushels of Indian corn, 50,704 of oats, 78,990 of sweet potatoes, and 8,945 bales of cotton. There were 47 churches, 2 newspapers, and 490 pupils attending public schools. It is traversed by the Mobile and Ohio and the Memphis and Charleston railroads. Capital, Jacinto.

TISSAPHERNES, a Persian statesman and general, killed in Colosse, Phrygia, in 395 B. C. He first appears in history as sent by Darius Nottus in 414 to quell the revolt of Pisuthnes, satrap of Lower Asia, and in pursuance of this object made a treaty with the Spartans, who assisted him in the capture of Amorges, the son of Pisuthnes. The alliances made by

the Greeks with the treacherous Persian were never of long duration, as he managed his power so as not to render either Athens or Sparta completely triumphant, and thus made himself an object of suspicion and dislike to both parties. In 407 Cyrus the Younger was appointed viceroy of the maritime region of Asia Minor. A mutual hostility soon sprang up between the prince and the satrap, and after the death of Darius the latter accused the former of aspiring to the throne of his brother Artaxerxes. Involved in constant disputes and wars with the prince, he was the first to reveal to the king the news of Cyrus's intended expedition, and at the battle of Cunaxa in 401 was one of the 4 generals who commanded the Persian army. He gained possession, by treachery, of the persons of the 5 generals commanding the Greek mercenaries of Cyrus, put them to death, and during the famous retreat of the 10,000 under Xenophon continually harassed them on their march as far as the Carduchian mountains. For his services Tissaphernes, in addition to his own satrapy, was made governor of the provinces ruled by Cyrus, and in this position carried on a war with the Spartan generals Thimbron, Dercylidas, and Agesilaus, by the last of whom he was outmaneuvered and badly beaten. Complaints against the timid and treacherous satrap were now sent to the Persian court, and these were supported by the influence of Parysatis, the queen mother, who wished to revenge the death of her favorite son Cyrus; and Tithraustes was accordingly sent down to put Tissaphernes to death. The disgraced satrap was surprised in the bath, slain, and his head sent to Artaxerxes.

TISSOT, SIMON ANDRÉ, a Swiss physician, born in the canton of Vaud in 1728, died near Lausanne, June 15, 1797. He was educated at the universities of Geneva and Montpellier, and about 1750 established himself in Lausanne, where he rapidly rose to great eminence as a practitioner and professor in the university. Having declined various flattering offers from foreign courts and universities, he in 1780 accepted the professorship of clinical medicine in the university of Pavia, tendered to him by the emperor Joseph II.; and during his residence there the students, in consequence of his successful treatment of an epidemic bilious fever, caused a marble inscription, commencing with the words *Immortali Praeceptorum*, to be placed under the portico of the school. In 1788 he returned to Switzerland. His works, of which a complete edition was published by J. N. Hallé (11 vols. 8vo., Paris, 1811), comprise *Acis au peuple sur la santé* (12mo., Lausanne, 1761), which has been translated into every European language and frequently reprinted; *De Valitudine Literatorum* (1766), also frequently reprinted; *Essai sur les maladies des gens du monde* (Nuremberg, 1770); *Traité des nerfs et de leurs maladies* (4 vols., Lausanne, 1778), and numerous other treatises. He also edited Morgagni's works, with a memoir.

TITANIUM, a metal first detected in 1791 by Gregor in titanite iron, and found by Klaproth in 1794 in rutile, and named by him from the Titans. Dr. Wollaston in 1822 recognized it in the form of minute copper-colored cubical crystals found in the slags of the iron smelting furnaces at Merthyr Tydvil in South Wales, and these, often met with since that time in iron slags, have been until recently regarded as pure titanium, but are now understood to be compounds of the metal with nitrogen and cyanogen. Berzelius was the first to separate this metal in a state of purity. He did this by decomposing a mixture of the fluorides of titanium and potassium by means of metallic potassium, and obtained the metal in a grayish powder. M. St. Clair Deville obtained it in forms resembling specular iron ore, crystallized in prisms with a square base. Its chemical equivalent is 25; symbol Ti. Three oxides of the metal are known, TiO , Ti_2O_3 , and TiO_2 ; the last of which, titanate acid, is the only one of interest. It occurs as a mineral in 3 forms: as rutile and anatase, which both crystallize in the dimetric system, though with different angles, and as brookite, crystallizing in the trimetric system. Rutile is generally a reddish brown mineral, sometimes yellowish or black, harder than feldspar, and of specific gravity 4.18 to 4.25. It occurs in many parts of Europe and America, the richest localities in the United States being in Chester and Lancaster cos., Penn. In Vermont and New Hampshire, as also in Brazil and Switzerland, it is found in long needles enclosed in masses of transparent quartz, making very curious and beautiful specimens, which are often used in jewelry. Anatase and brookite are comparatively rare minerals. In combination with oxide of iron, titanate acid forms the compound ilmenite or titaniferous iron, of which as an iron ore mention is made in the article IRON. This is met with in large masses in Maryland, northern New York, and Canada. At Bay St. Paul on the St. Lawrence are beds of it, from 100 to 300 feet long and 90 feet thick, the ore, according to Mr. T. S. Hunt, containing 48.60 per cent. of titanate acid combined with 37.06 of protoxide of iron, 10.42 of peroxide of iron, and 8.60 of magnesia.—The only useful application of titanium is to furnish a yellow color in porcelain painting, and to give the proper tint to artificial teeth. The American supply for these purposes is derived from Pennsylvania.

TITANS AND TITANIDES, in Greek mythology, the sons and daughters of Uranus (Cælus) and Gæa (Terra). The names of the Titans were Oceanus, Cœus, Crius, Hyperion, Iapetus, and Cronos (Saturn); those of the Titanides, Theia, Rhea, Themis, Mnemosyne, Phœbe, and Tethys. According to the Hesiodic account, Uranus feared his offspring, and as fast as they were born confined them in the cavities of the earth; and Gæa, who could not make room for them, produced iron and endeavored to persuade them to free her and them-

selves from this oppressive treatment. Cronos alone had the courage to undertake the deed, and, armed with a sickle made by his mother, emasculated his father, and thus secured liberty and power for himself and his brothers. Marrying his sister Rhea, he begat 3 sons and 8 daughters, but, having been told that he would be destroyed by one of his own children, swallowed them as soon as they were born. Rhea by the aid of Uranus and Gæa concealed Zeus (Jupiter), the youngest, in a cavern on Mt. Ida, giving to Cronos instead a stone wrapped in swaddling clothes. When Zeus had grown up, he was enabled by stratagem to make his father vomit up the stone and the 5 children he had swallowed, and now determined to wrest the supreme power from the hands of Cronos and the Titans. Supplied by the Cyclops with thunder and lightning, and aided by the Centimanes, he carried on a war against the Titans for 10 years, himself and his allies occupying Olympus, while the opposing gods were encamped on Mt. Othrys. At length Zeus triumphed. The Titans, with the exception of Oceanus, were confined for ever in a subterranean dungeon, where a wall of brass was built about them by Poseidon (Neptune), and where they were guarded by the Centimanes.—The name of Titans was also given to those beings who were their descendants, such as Prometheus, Hecate, and others.

TITHES, a tax of one tenth of the increase of crops, stock, and avails of personal industry, formerly and still in some countries levied for the support of the officers of religion, religious worship, or the assistance of the poor. This tax seems to have been of patriarchal origin (Gen. xiv. 20), and existed in many of the nations of antiquity. Under the Jewish theocracy the tenth part of the increase of the property of the Jews was accorded to the Levites, as a substitute for the landed inheritance they forfeited by their consecration to the temple worship, and also as a compensation for their services. Other tithes were also prescribed for the sacrifices of the temple, and at particular periods for the poor. (See TAXES.) The early Christian church adopted voluntarily the custom of consecrating to religious purposes the tenth of the income; and it was not till after the church wielded the temporal power that tithes were the subject of legal enactment. It was during the dark ages extended over the greater part of Catholic Europe. In France, Charlemagne established them by decree in the 8th century. In England the first law in relation to them is believed to have been that of Offa, king of Mercia, who brought the civil power to the aid of the clergy in collecting their tithes. This was subsequently extended over the whole of England by Ethelwulf. In the 9th century they were also made legally obligatory in Scotland, and not long after in Ireland. At first they were paid to whatever church the payer chose, but the decretal of Pope Innocent III. directed their

payment to the parsons of the respective parishes in which they arose. Tithes were by the ecclesiastical law divided into 3 kinds: "prædial," or such as arose immediately from the ground, like grain of all kinds, fruits, herbs, grasses, hops, wood, &c.; "mixed," natural products, but nurtured and preserved in part by the care of man, such as wool, milk, pigs, butter, cheese, &c.; and "personal," as of manual occupations, trades, fisheries, and the like. The first two kinds are payable in gross, but of the third class only the tenth part of the clear gains and profits is due. In France, Charlemagne divided the tithes into 4 parts, one to maintain the edifice of the church, another to support the poor, a third to maintain the bishop, and a fourth the parochial clergy. By the original law in England, all lands except those of the crown and of the church itself were tithable; but at the reformation many of the forfeited church lands when sold were specially exempted, and some were also exempted by composition and some by prescription. These partial exemptions only made the burden more galling to those who were compelled to pay; and as the tithes were a tax for the support of the clergy of the established church, it was particularly annoying to dissenters, and has been for the past 150 years a constant subject of complaint. Until the reign of William IV. the payment of tithes might be exacted in kind, but by the act of 6 and 7 William IV. c. 71, a board of commissioners was appointed for the purpose of converting them into a rent charge payable in money, but varying annually according to the average price of corn for the preceding 7 years. They have now been thus converted throughout the greater part of England, and their former amount somewhat reduced; but the amount raised from them still exceeds \$10,000,000. In Ireland they have been compounded at $\frac{1}{4}$ their former estimated value. In France tithes were abolished at the revolution, and this example was followed afterward by the other continental states. The Greek church has recommended, but never legally enforced, the payment of tithes. In the United States tithes are only exacted by the Mormon hierarchy, and among them the system bears a close resemblance to that of the Jewish theocracy.

TITIAN (TIZIANO VERONESE), an Italian painter, born in Cadore, Friuli, in 1477, died in Venice, Sept. 9, 1576. He displayed in infancy a remarkable predilection for painting, and is said to have made his first attempts at coloring with juices expressed from flowers. At 9 years of age he was placed under Sebastian Zuccati, a Venetian painter and worker in mosaic, whom he left to enter the school of the Bellini, in which he acquired the essential elements of his art, with somewhat of the antiquated manner of his masters. He also came probably under the influence of Albert Dürer, who visited Venice in 1494 and again in 1507, but was indebted chiefly to his friend and fellow pupil Giorgione for those ideas of art and color, re-

flecting the cheerful enjoyment of life and its splendor, which thenceforth characterized the productions of the Venetian school. For a time the two young painters were bound to each other by the closest ties of friendship; and such was the overpowering influence of Giorgione's genius and personal character, that it was not until he had entered far into manhood that Titian can be said to have shown any decided originality. At Giorgione's death in 1511 the styles of the two artists were so closely assimilated that it was difficult to distinguish their productions, and hence it was a comparatively easy, as it was a natural task, for Titian to complete the unfinished works of his friend. A new era thenceforth commenced in his development. Perceiving that breadth of form produced breadth of color, he endeavored to see nature in a more ample light, and, instead of copying or imitating her tones, to generalize and elevate them in accordance with his own original conceptions. The result was a free and serene beauty of form and expression, and a representation of life realizing what Kugler calls "the glorification of earthly existence, and the liberation of art from the bonds of ecclesiastical dogmas." Left at the age of 35 without a rival worthy of competing with him, Titian immediately entered upon a career which for the uniform excellence of its productions, for celebrity and duration, has perhaps no parallel in the history of painting. Commissions from the wealthy Venetian nobility afforded him abundant employment at home, and for two years subsequent to 1514 he resided at the court of Duke Alfonso I. of Ferrara, for whom he painted three celebrated mythological pictures, the "Arrival of Bacchus in the Island of Naxos" and "A Sacrifice to the Goddess of Fertility," both of which are now in the gallery at Madrid; and the "Bacchus and Ariadne" in the British national gallery, which presents on a small scale an epitome of all the characteristic beauties of Titian in composition, color, and form. At Ferrara he also painted portraits of the duke's wife, the celebrated Lucrezia Borgia, and of Ariosto. In 1516 he was back in Venice, having resisted a pressing offer from Leo X. to visit Rome, where Raphael was then executing his grand series of frescoes in the Vatican, and one also from Francis I. of France; and for a number of years he was too fully occupied with the commissions of local patrons to find time to practise his art abroad. In 1580, however, he repaired to Bologna, where the emperor Charles V. and Pope Clement VII., each surrounded by a brilliant court, had met in conference; and through the influence of the cardinal Ippolito de' Medici, the pope's nephew, he was enabled to paint the portraits of both potentates. The emperor, whom he represented on horseback, with lance in rest, loaded him with honors and rewards; and after a brief residence in Mantua, where among other works he executed for Federico Gonzaga portraits of 11 of the 12 Cæsars, Titian returned

to Venice. In 1582 he was again in Bologna at the request of the emperor; and between 1582 and 1585, according to the commonly received account, he resided in Spain, where he is said to have executed the most important of his works now in that country. Later researches, however, have rendered it doubtful whether he ever visited Spain at any time. His style of living had hitherto been frugal and unpretending, notwithstanding the great reputation he enjoyed throughout southern Europe; but as he approached old age he began to live with splendor. The most powerful princes of Europe were eager for specimens of his art, and their demands, together with his own enthusiasm, afforded constant incentives to his industry. At 65 years of age he retained the vigor and freshness of youth, while the magic charm of his color and the cheerful serenity of his style seemed to mellow with time. He was the intimate friend of the poet Aretino and the architect Sansovino, and his position as painter to the republic brought him into familiar relations with the chief aristocracy of Venice. In 1543-'5 he revisited Bologna and Ferrara, where he painted the emperor Charles V. for the 8d or 4th time, and Pope Paul III.; and after passing some time in the employment of the duke of Urbino, he repaired to Rome. His finest production here was the picture of the old pope with his nephews, Cardinal Farnese and Duke Ottavio Farnese, which is in every respect a masterpiece of historical portraiture. While engaged in this city upon a picture of Jupiter and Danaë, he was visited by Michel Angelo, who, after expressing admiration of his coloring, observed that if he had been early grounded in the principles of drawing, he would rank as the first painter in the world. In 1548 he was summoned by Charles V. to Augsburg, where he was created a count palatine of the empire (although this distinction is also said to have been conferred upon him during his alleged residence in Spain), and placed on the imperial pension roll. After the abdication of Charles he continued in great favor with his successor Philip II. of Spain, for whom he painted a number of important works; but his pension was thenceforth constantly in arrears, and he was frequently obliged to petition the Spanish officials for the sum due him for pictures. The remainder of Titian's life was passed principally in Venice, but it was long before his pencil gave indications of the weakness or timidity of age. His "Martyrdom of St. Lawrence," in the Jesuit's church in Venice, painted when he was 81, is one of his largest and grandest compositions; and at least one of his celebrated Magdalens, that in the Escorial, was executed even later. At 90 years of age sorrow rather than time began to affect him, and, notwithstanding he clung resolutely to his art for consolation, the vigor and beauty of his style became impaired. In his 97th year he received Henry III. of France, who passed through Venice on his way from Poland, with a mag-

nificence of hospitality and a courtly grace of manner which charmed all beholders; and two years later, while yet occupied with his art, he fell a victim to the plague, the fatal consequences of which he might have escaped had the nature of the distemper been understood by the Venetian physicians. His latest work, a dead Christ with the Virgin and attendant saints, now in the academy of Venice, "shows certainly," says Kugler, "that his hand trembled beneath the weight of ninety and nine years; but the conception of the subject is still animated and striking, the colors still glowing, while, Titian-like, the light still flows around the mighty group in every gradation of tone." By a special exception in his favor he was buried in the church of Santa Maria de' Frari, where a black marble slab, inscribed "Tiziano Verocellio," marks his resting place.—The works of Titian comprise sacred and profane history, mythological subjects, portraits, and landscapes, the last named being generally treated in connection with other subjects, though not always in subordination to them. His long life and unceasing industry will account for the enormous number of pictures passing under his name distributed among the galleries of Europe, many of which, however, are not well authenticated. He is still seen to the best advantage in Venice. Of his early pictures, which reflect the style of the Bellini modified by the peculiar ideas derived from Giorgione, the most noticeable are the "Visit of Mary to Elizabeth," in the academy at Venice; the *Vierge au Lapis*, in the Louvre; the "Christ with the Tribute Money," at Dresden; and particularly the "Resurrection," painted in 5 compartments, in the church of S. Nazaro, at Brescia. The more developed period which succeeded the death of Giorgione comprises nearly all the pictures by which he is now known, and of these only the chief ones can be here designated. The first in celebrity of these perhaps is the "St. Peter Martyr," in the church of S. Giovanni e Paolo in Venice, which ranks with the "Martyrdom of St. Lawrence" among the painter's masterpieces, and which, for invention, action, and the grandeur of the landscape, has always been considered of the first order of excellence. The academy of Venice contains his "Assumption" and "Presentation of the Virgin," and the Manfrini palace in the same city the "Entombment of Christ," which Kugler considers "perhaps the most important of Titian's pictures, and the noblest representation of the subject." In addition to these may be mentioned the "Last Supper," in the Escorial, upon which the artist informed Philip II. he had labored 7 years; a "Virgin and Child with Saints," in the Uffizi gallery; the "St. Sebastian," in the Vatican; the "Christ crowned with Thorns," in the Louvre; various well known Magdalens in Rome, Florence, the Escorial, and elsewhere; and numerous Madonnas, Holy Families, and similar pieces scattered over Europe. Upon

subjects taken from allegory and secular history he executed several important pictures, including the "Victory of the Venetians over the Janizaries," for the doge's palace, which were destroyed by fire. As a colorist merely Titian developed the resources of his art with most success in the naked female figures which are so frequently met with in his mythological pictures; although he is here not unfrequently betrayed into an ostentatious exhibition of his mastery over his materials. Of this class of his works the most familiar examples are the several Venuses in the galleries of Florence and Dresden; the Danaës at Naples and Vienna; the Flora in the Uffizi gallery; "Diana and her Nymphs" and "Venus rising from the Sea," in the Stafford gallery; "Venus and Adonis" (a duplicate), in the British national gallery; and the so called *Venus del Pardo* in the Louvre. In the romantic symbolical style developed by Giorgione he produced many pictures combining his characteristic excellences as a painter of landscape and figures, of which the "Three Ages" in the Bridgewater collection, and "Sacred and Profane Love" in the Borghese palace, may serve as examples. As a portrait painter he is still unrivalled, whether we consider the "senatorial dignity" of his old Venetian nobles, "by the side of whom all modern gentlemen look poor and small," or the glowing beauty and happy consciousness of existence which characterize the celebrated female portraits known as "Titian's Mistress," in the Louvre, *La bella di Tiziano* in the Uffizi gallery, and the various "Titian's Daughters," all widely known through copies. Nearly every great potentate of Europe of the 16th century was painted by him; and soldiers, statesmen, poets, and ecclesiastics almost without number were among his sitters. The list includes Charles V., of whom he executed several portraits; his successors Ferdinand I. and Rudolph II.; Philip II. of Spain, whom he also painted several times; Francis I. of France; the sultan Solymán II. and his wife Roxana; Popes Clement VII., Paul III., and Paul IV.; all the doges of his time; Francesco, duke of Urbino, and his duchess, Eleonora; the constable de Bourbon; the cruel duke of Alva; Andrea Doria, doge of Genoa; Cesare Borgia; Count Castiglione; Cardinals Ippolito de' Medici, Bembo, Sforza, and Farnese; the poets Ariosto, Aretino, Fracastaro, and Bernardo Tasso; the architect Sansovino, and many others, the whole comprising a collection which would form a complete historical gallery illustrative of the times in which he lived. Lastly, as Fuseli has remarked, "landscape, whether it be considered as the transcript of a spot, or the rich combination of congenial objects, or as the scene of a phenomenon, dates its origin from him."

TITICACA, LAKE, in the republic of Bolivia, South America, occupies the centre of one of the most remarkable terrestrial basins known on the globe. It is 160 m. long and from 50

to 80 broad, and discharges through the valley of El Desaguadero, to the S. E., into another lake called Lake Aullagas, which is probably kept at a lower level by evaporation or filtration, since it has no known outlet. The surface of the lake is 12,846 feet above the sea, and it is the most elevated body of water of similar size in the world. It has been sounded to the depth of 120 fathoms, but is supposed to be much deeper. The level of its waters has decreased very much in the historical period; and it is evident that they once surrounded the elevation supporting the ruins of Tiahu-nico, 12 m. distant. Vast quantities of rushes grow on the shores of the lake, frequented by water fowl, and 7 or 8 varieties of fish are peculiar to its waters. Its W. side is barren, excepting in gold-washings and mines of silver and copper. On the E. shore, maize, wheat, and the fruits of the temperate zone flourish in great perfection, and here also are found considerable quantities of timber. Although far removed from the ordinary channels of travel and trade, almost inaccessible, and in parts stony and sterile, the country bordering Lake Titicaca supports a population of more than 1,000,000. It seems to have been the seat of the highest and most ancient civilization of South America, and of a people who have left gigantic monuments of their power and skill. (See TIHUANICO.) It was from this centre, according to the traditions of the Incas, that the great lawgiver and teacher of the Peruvians, Manco-Capac, diffused his influence; and it has also been maintained that here was the original seat of the Aymara or Inca race.

TITLARK, the popular name of the small denti-rostral birds of the sub-family *motacillinae* and genus *anthus* (Bechst.). They resemble the larks in their markings and in the long hind claw, and the wagtails in their movements and habits on the ground, and evidently are intermediate between these sub-families. In this genus the bill is rather straight and slender, with the tip notched; wings very long, the first 8 quills equal and longest, and the tertials nearly as long as the primaries; tail moderate and slightly notched; tarsi and toes long and slender, the hind toe long with a very long sharp claw. The species are numerous, inhabiting most parts of the world and in every variety of region, some being migratory, others permanent residents. The nest is made upon the ground, of dry grass and stalks, lined with finer plants and hair, and the eggs are 4 to 6. The American titlark (*A. ludovicianus*, Licht.) is 6½ inches long and 11 in alar extent; olive brown above, each feather darkest in the middle; beneath yellowish brown, the sides of the neck spotted longitudinally with dark brown; around eyes and superciliary stripe yellowish; central tail feathers like back, the others blackish brown, the external one mostly white and a white spot at the end of the 2d; primaries edged with whitish, and the other quills with pale brownish; bill and feet black. It is very

generally distributed over North America, extending to the Pacific and to Greenland, and is accidental in Europe. The flight is exceedingly easy and graceful; it occurs in flocks of tens or hundreds, running fast on the ground, vibrating the tail whenever it stops, not squatting like the larks, but moving the body on the upper joints of the legs; it often alights on fences and branches, walking on them with ease. It is found in the fields, on the prairies, along rivers, and on the sea shore; the notes are clear and sharp tweets, the last much prolonged; it breeds as far N. as Labrador, both sexes incubating, and sitting so closely as almost to allow themselves to be trodden upon before flying; the eggs are 6, $\frac{4}{5}$ by $\frac{1}{4}$ inch, reddish brown, with darker dots and lines at the larger end. It is very similar to the *A. obscurus* and *spinoletta* (Bechst.) of Europe, though the latter has a longer bill and less slender tarsi and toes, and has no yellowish superciliary stripe; the outer tail feathers are not white, and the spots are less distinct below.—The Missouri titlark (*neocorys Spraguei*, Sclater) is 5 $\frac{1}{2}$ inches long and 9 $\frac{1}{2}$ in extent of wings; it is a stouter bird than the last, with shorter bill and tail and larger feet and hind toe; the 1st quill is the longest; it is wood-brown above, the feathers light-edged, and dull white below, with less numerous spots on the breast; the legs and bill are yellow. It is found in Nebraska, and in song and habits comes the nearest of American birds to the European skylark.—Among the European species the most extensively distributed is the meadow titlark or pipit (*A. pratensis*, Bechst.), also called titling; it is 6 $\frac{1}{2}$ inches long and 9 $\frac{1}{2}$ in alar extent, olivaceous above, spotted with dusky; brownish white below, tinged anteriorly with red; neck, sides, and fore part of breast with oblong brownish black spots. It is of slender and elegant form, generally distributed over Europe, a permanent resident in Great Britain, and most abundant in meadows; it sings from the middle of April to the end of July, and rears 2 broods in a season; its notes are remarkably fine, uttered when perched, seated, or flying, in the latter case commencing at a considerable height, hovering a little while, and descending warbling to the ground. It is in the nest of this species that the cuckoo generally places its eggs to be hatched by parents not their own. The tree titlark (*A. arboreus*, Bechst.) is 6 $\frac{1}{2}$ inches long and 11 $\frac{1}{2}$ in alar extent, much like the last, but with thicker bill and shorter and more curved hind claw; it prefers wooded districts, and perches on trees much of the time, whence its name; the song is more mellow and modulated and longer continued than in the preceding species, the bird beginning it from the top of a bush or tree, rising like a skylark, but to a moderate height, then with outstretched wings and expanded tail making a half circle in its slow descent till it reaches a treetop again; it is migratory in England. The shore titlark (*A. obscurus*, Bechst.) is 6 $\frac{1}{2}$ inches long and 10 $\frac{1}{2}$

in alar extent; above dull olivaceous with obscure dusky streaks, and yellowish gray below. It is called also rock and sea lark. It frequents the sea shore, following the retreating tide, searching for small mollusks and crustaceans with the wading birds; its song is a shrill and not very agreeable warble, performed in the air; it is most abundant in S. Europe.

TITLES OF HONOR, designations by which persons are addressed in consequence of some office or dignity in their possession or inherent in them. The Greeks used them sparingly, and they were bestowed among the Romans chiefly upon men who had gained particular distinction in certain offices, in which case the designation became hereditary. Thus the honorary title of *Magnus* pertained to the descendants of Pompey, as those of *Africanus* and *Asiaticus* did to the Scipio gens. Other offices carried their titles with them, independent of the merits or services of the incumbent, and the words Cæsar, originally the name of a family, Augustus, and *pater patriæ*, were gradually applied indiscriminately to all who held the imperial throne. The title "illustrious," previously given only to those who had gained reputation in arms or letters, became in the reign of Constantine the Great hereditary in the families of princes, and thenceforth every son of a prince was illustrious. Toward the decline of the empire the emperors styled themselves divinites, and were addressed as "your perpetuity," "your eternity." The title most esteemed of all, however, and which preserved its significance the longest, was that of a Roman citizen. The titles assumed by European sovereigns, whether emperor, king, czar, or prince, are invariably accompanied by certain complimentary phrases of address, as "your majesty," your "royal highness," which are generally common to all of them. Previous to the accession of the Tudors the sovereigns of England were addressed as "your grace." Henry VIII. first assumed the title of highness, which was formerly given only to kings, and which is still the prerogative of people of royal birth; and at the field of the cloth of gold in 1520 he was first called "your majesty" by Francis I. of France. This title however had been previously assumed by Charles V. James I. was the first "sacred majesty" of England, and he added to his titles those of "most dread sovereign, his highness, the most high and mighty prince, James I.," &c. The present occupant of the British throne is called "Victoria, by the grace of God, of the United Kingdom of Great Britain and Ireland, &c., queen, defender of the faith." The compellation "sire" (father) seems to have been peculiar to the kings of France. Elsewhere in Europe the practice does not differ greatly from that of England in the phraseology of the terms applied to persons of the highest dignity, although in some countries, particularly Germany and Spain, the national taste has invented the most inflated titles for the sovereign. It is related that the emperor Charles V. hav-

ing filled the first page of a letter to Francis I. with a list of his own titles, the latter prince in his reply styled himself simply king of France, citizen of Paris, and lord of Vauves and Gentilly. A similar anecdote is related of the banker Zamet, who, when asked by a notary by what title he wished to be designated in a legal document, replied: "Call me owner of 1,700,000 crowns." European potentates, however, are far surpassed in the number and magnificence of their titles of honor by those of other parts of the world. Thus the king of Ava in writing to a foreign sovereign calls himself "the king of kings, whom all others should obey; the cause of the preservation of all animals; the regulator of the seasons; the absolute master of the ebb and flow of the sea; brother to the sun; and king of the four and twenty umbrellas," the last named title having reference to the umbrellas carried before him as a mark of his dignity. Some royal titles, which would not be very reputable in European countries, are nevertheless highly valued in other parts of the world; and the king of Monomatapa in southern Africa is pleased to be addressed by his flatterers as "great magician" and "great thief." Certain Roman Catholic sovereigns prefix to the title of majesty common to all of them a qualifying epithet, commonly called a predicate, as "catholic" for Spain, "most faithful" for Portugal, and "apostolic" for Hungary. Under the old régime the king of France was called "his most Christian majesty."—The various orders of nobility in England are carefully distinguished by titles of honor, by which in legal proceedings and on certain public occasions the representatives of them are designated. The qualifying epithets by which such persons are addressed are also nicely graduated in accordance with the kind and degree of the dignity possessed by them, the baron being styled simply "right honorable," while a duke is addressed as "your grace," and the "most noble," and upon certain occasions as "most high, potent, and noble prince." In like manner the baron is addressed by the crown as "right trusty and well beloved," and the duke as "our right trusty and right entirely beloved cousin and councillor." The children of peers have also their titles of honor, such as honorable, lord, or lady, which however are not hereditary. The continental orders of nobility correspond generally with those of England, but the compellations of the persons possessing these dignities exhibit many minute and nice distinctions. The degrees of ecclesiastical rank are no less carefully distinguished. The pope is styled "his holiness," a cardinal "his eminence," an archbishop "his grace," and so on, down to the possessors of the inferior dignities, who both in Europe and America generally adopt the prefix of "reverend." In England the archbishops of Canterbury and York, beside the title of "grace," style themselves "by divine providence" and "by divine per-

mission;" and the bishops are addressed as "lords" and as "right reverend." The degree in which the holders of civil offices are addressed by titles of honor varies considerably in different parts of Europe; and while in England comparatively few persons are so distinguished, the Germans regard the insignificance of the office as no obstacle to a recognition of the title pertaining to it. The tax-gatherer is not unfrequently addressed as "Mr. Tax-gatherer," and his wife as "Mrs. Tax-gatheress;" and the title of *Rath* or councillor has been so widely distributed through all the branches of the government, and often in such infelicitous connections, that its significance is greatly impaired. It may be observed that the title Mr., formerly a compellation of respect, is now the common prerogative of persons in Great Britain who have no hereditary or official title, and is universally so applied in the United States. An analogous practice prevails on the continent of Europe. In the state of Massachusetts the governor is entitled by law to be addressed as "his excellency," and the lieutenant-governor as "his honor;" and a similar privilege pertains to the same offices in a few other states of the American Union. All other officials have the sanction of custom or courtesy only for the titles of honor by which they are addressed. Judges are invariably addressed upon the bench as "your honor," and custom has given the same title to the mayors of cities and a few other officials. Judges, members of congress, and in some states the members of the upper house of the legislature, are frequently styled "honorable," although the practice is by no means universal; and the president of the United States receives the courtesy title of "his excellency." The clergy are universally addressed as "reverend," and those having episcopal functions adopt the prefix of "very" or "right." (See *ESQUIRE*.)

TITMOUSE, the popular name of the *parina*, a sub-family of the warblers, found in all parts of the world except South America. The bill is short, strong, rather conical and straight, with the tip entire; nostrils generally concealed by the frontal plumes; wings moderate and pointed, with the first 8 quills graduated; tail more or less long, rounded and even; tarsi long, slender, and scaled in front; inner toe shortest; claws strong and curved.—In the typical genus *parus* (Linn.) the bill is somewhat curved, not very stout; the head is not crested; the 4th and 5th quills are equal and longest; the crown and throat generally black. There are more than 50 species described in North America, Europe, Asia, and Africa, small, sprightly, and bold birds, and many of them with beautiful colors; they frequent woods and gardens, fitting from branch to branch, running rapidly up and down the limbs, and hanging in various attitudes from the twigs in searching for food, which consists of insects, larvae, graine, and seeds; they will also eat flesh and carrion, and attack young

and sickly birds, which they kill by strokes of the bill; they approach farm houses in severe weather, and in the spring sometimes do considerable damage in orchards by picking open the buds in search of insects. The nests are made in the forks of bushes and trees, of moss, grasses, and wool, lined with hair and feathers; many of the best known species deposit their eggs in holes of decayed trees, left by the woodpeckers or made by themselves; the eggs are 6 to 12; it is said that some of the foreign long-tailed species construct an oval nest with 2 opposite orifices for ingress and egress through which the tail projects; this is denied by Macgillivray. In warm climates they seem to prefer mountainous districts, some of the Indian species being found at an elevation of more than 7,000 feet; even in temperate zones many raise 2 broods in a year, laying many eggs, but fewer for the 2d brood; the young are fed chiefly on caterpillars, and hence these birds are among the farmer's best friends.—The largest of the well known American species is the tufted titmouse (*Lophophanes bicolor*, Bonap.), 6½ inches long and about 10 in alar extent; the crown has a conspicuous crest, the bill is conical with the upper and lower outlines convex, wings graduated with the first quill very short, and the tail moderately long and rounded. The color above is ashy black; frontal band black; under parts uniform whitish, sides brownish chestnut; sides of head nearly white, and bill black. It is found throughout eastern North America to the Missouri, appearing in the middle states about May 1, in the summer inhabiting the forests, in flocks or families of 8 or 10, in company with the nuthatch and downy woodpecker; the flight is short, with jerks of the body and tail; the note is a kind of pleasing whistle; it is fond of nuts, which it holds in the claws, breaking the shell with the beak; like most others of the genus, it attacks smaller birds; the eggs are 6 or 8, white with a few red spots at the larger end, and are laid in holes of decayed trees.—In the genus *parus* (Linn.) belongs the black-capped titmouse or chickadee (*P. atricapillus*, Linn.), 5 inches long and 7½ in extent of wings; the back is brownish ashy, top of head and throat black, sides of head white; below whitish tinged with brownish on the sides; outer tail feathers, some of the primaries, and secondaries margined with white; wings brown. It is found in eastern North America along the Atlantic border, according to Audubon rarely met with S. of Maryland and Kentucky; it is very common in the fur countries and as far N. as lat. 65°. It is hardy, restless, industrious, and frugal, breeding in the most retired parts of the forest, being at this time very shy, but familiarly approaching houses in winter; when the pathless woods are covered with snow and the cold is 20° below zero, this little bird cheers the woodcutter and the traveller with its musical "chick-a-dee-dee," grateful for any crumbs left from their dinner; it is truly omnivorous,

and often attacks young birds; the nest is generally in a hole made by a woodpecker or by itself, not more than 10 feet from the ground, purse-shaped, and lined with soft hairs; the eggs are 6 to 8, ½ by ¼ inch, white with light reddish dots and marks; 2 broods are raised in a year; the flight is short, with a murmuring sound. Species resembling this occur in the southern and western states, Mexico, and on the Pacific coast. The Hudson's bay titmouse (*P. Hudsonicus*, Forst.) is 5 inches long and 7 in alar extent; yellowish olive brown above, purest on head; chin and throat dark sooty brown; sides of head and lower parts white; sides of body and anal region light chestnut; no white on wings or tail, the last nearly even. It breeds from Labrador to Maine, rarely coming S. of the latter, and going further N. than any other species.—The largest of the European species is the great titmouse or tit (*P. major*, Linn.), called also ox-eye and black-cap in England, and *la charbonnière* in France; it is less than 6 inches long, with the head, fore part of neck, transverse band on sides, and longitudinal one on breast and abdomen, black; cheeks white, back yellowish green, and breast and sides yellow; wings and tail grayish. It is not a sociable bird; its usual note is a loud cheep followed by a harsh chatter, in the spring resembling the filing of a saw and heard to a great distance; it imitates the notes of other birds, and in its habits and food shows an alliance to the jays; in its search for flies it visits the cottage tops and pulls the straw from the thatch; it is found from Norway and Sweden to the southern boundaries of Europe. The blue tit (*P. caeruleus*, Linn.) is 4½ inches long and 7½ in alar extent, with the upper part of the head light blue and encircled with white; band round neck, and before and behind eyes, duller blue; cheeks white, back light yellowish green, under parts pale grayish yellow, and middle of breast dull blue. This is the handsomest and most familiar species; in autumn it quits the woods and thickets and visits the gardens and orchards, incessantly hopping about among the branches, pert and irritable; it is called town-tit, blue-cap, blue-bonnet, and billy-biter in various parts of England. This bird, among others, has been frequently watched in Great Britain while rearing the young, and the parents have been found to carry to the nest on an average a grub every 2 minutes during the day, beside supplying their own wants. It is a permanent resident in Great Britain; it is very bold when sitting, hissing like a snake or angry kitten, and severely biting the hand brought near the nest. The crested tit (*P. cristatus*, Kaup) is a beautiful bird, having a crest on the crown like the American tufted species; it is 4½ inches long and 8 in alar extent, the feathers of the head black with white margins; upper parts gray tinged with yellowish brown; it is found in the pine and juniper regions of Europe.—The long-tailed tit (*Mecisturus caudatus*, Leach) is about 6 inches long and 6½ in ex-

ent of wings; the plumage is very soft, the bill black and much concealed by the feathers at the base, whence it is called muffin; other names are bottle tom-tit and poke pudding; head, throat, and breast white; broad band over eyes, nape, and back black; scapulars reddish; lateral tail feathers on each side externally white, the rest black; the tail is twice as long as in any other European species, and the bill very short and convex; the nest is made on bushes and trees.—In the genus *paroides* (Koch) the bill is more slender and nearly straight; the species are found in the neighborhood of water, among the reeds on the borders of rivers, lakes, and marshes, the nest interwined beyond the reach of the water; the food consists chiefly of insects and seeds; in the bearded tit (*P. biarmicus*, Koch) of Europe,

the head and neck are bluish gray, the upper parts, abdomen, and sides yellowish brown, and there is a tuft of pendent feathers between the bill and eyes; the gizzard is very muscular, unlike the true tits, on which account some have placed it among conirostral birds; mollusks like *succinea* and *pupa* are swallowed whole, but the shells are soon broken up by the stomach. The hanging tit (*P. pendulinus*, Koch), 4½ inches long, is reddish gray above, with wings and tail blackish, and lower parts rosy white; it is found in eastern and northern Europe, and constructs very artistically a nest woven of the fibres of bark and the cotton of the seeds of willows, fastened to a reed or thin branch and surrounded by close-tangled bushes, which protect it from the wind and hide it from view.—A species from Java (*peathria exilis*, Temm.) is but a little over 3 inches long.

TITTMANN, JOHANN AUGUST, a German theologian, born at Langensalza, near Gotha, Aug. 1, 1773, died in Leipsic, Dec. 31, 1831. He studied theology and philosophy at the universities of Wittenberg (where his father was professor) and Leipsic. In 1796 he was appointed extraordinary professor of philosophy, and in 1800 extraordinary and in 1805 ordinary professor of theology at Leipsic. The latter position he retained until his death. He is the author of numerous theological works, of which the most important are a "Cyclopædia of Theological Science" (Leipsic, 1798), and a "History of Theology and Religion in the Protestant Church during the second half of the 18th Century" (Breslau, 1805). He also edited the symbolical books of the Lutheran church (*Libri Symbolici*, Leipsic, 1817) and the Greek New Testament (Leipsic, 1824). At the congress of Vienna he vainly advocated the reorganization of the *Corpus Evangelicorum*, a supreme tribunal for the Protestant churches of Germany.

TITUS, a N. E. co. of Texas, bounded N. by the upper fork of Red river, S. by Big Cypress bayou, and intersected by White Oak bayou; area, 1,100 sq. m.; pop. in 1860, 9,648, of whom 2,488 were slaves. The surface is generally level and the soil fertile. The produc-

tions in 1860 were 66,000 bushels of Indian corn, 8,088 of oats, 292 bales of cotton, and 39,175 lbs. of butter. There were 4 churches, and 50 pupils attending public schools. Capital, Mount Pleasant.

TITUS (TITUS FLAVIUS SABINUS VESPASIANUS), a Roman emperor, born Dec. 30, A. D. 40, died near Reate in the Sabine country, Sept. 13, 81. He was the son and successor of Vespasian, and was educated in the imperial household with Britannicus, the son of Claudius, who was poisoned by Nero; and it is said that the future emperor tasted some of the same deadly potion and became sick in consequence. While still young he served as military tribune in Britain and Germany, and subsequently became quaestor. During the Jewish war he had command of a legion under his father, captured the cities of Tarichæa, Gamala, and other places, and also fell in love with Berenice, the daughter of Herod Agrippa. By reconciling his father and Mucianus, the governor of Syria, he was of invaluable service in contributing to the elevation of the former to the throne. When Vespasian went to Rome, he left Titus to end the Jewish war, which he accomplished on Sept. 8, 70, by the capture of Jerusalem and the massacre and dispersion of its inhabitants. Subsequently he returned to Rome by the order of his father, and proved by his prompt obedience that the rumors which charged him with aiming at the throne were unfounded. In that city he had the honor of a triumph along with his father for their common success in the Jewish war, and during the remaining years of the reign of Vespasian was employed in discharging the highest functions of state. He drew up the imperial edicts, and was permitted to write letters in the emperor's name. At the same time it was feared that his elevation to power would destroy the natural goodness of his character, as he began to be fond of the pleasures of the table and of indulging his licentious passions. After the capture of Jerusalem, Berenice had followed him to Rome, and at one time it was said that Titus wished to make her his wife; but out of deference to the feelings of his subjects, she was finally sent away from the city. He ascended the throne in 79, and by his conduct soon dispelled the ill-founded impression that he would be another Nero. His reign was marked by a succession of terrible calamities, the injuries inflicted by which he made earnest efforts to repair. The towns of Heroulanum, Stabia, and Pompeii were destroyed in that eruption of Vesuvius in which the elder Pliny lost his life; in 80 a great fire broke out in Rome which lasted 8 days, and consumed a large number of houses and many public edifices, among which were the capitol, the library of Augustus, and the theatre of Pompey; and moreover a plague began to ravage the city, of which thousands died daily. Titus almost exhausted his finances in order to relieve his unfortunate subjects, repaired many aqueducts, made a road from Rome

to Ariminum (the modern Rimini), completed the Colosseum, which his father had begun, and also constructed the baths called the baths of Titus. In dedicating these two last, he gave magnificent entertainments, which continued 100 days, on one of which 5,000 wild beasts were said to have been set fighting in the new amphitheatre. His reign was throughout marked by great clemency, checking all prosecutions of *lata majestas*, and punishing all informers. He did not even inflict the punishment of death upon those who conspired against his life, and pardoned his brother Domitian, who several times had attempted to get rid of him in order that he himself might ascend the throne. In 80 and 81 Agricola completed the subjugation of Britain. Meanwhile the health of Titus declined, and going to the Sabine country, he expired in the same villa in which his father had died. There were suspicions that Domitian, who succeeded him, was instrumental in procuring his death. Beside the letters and edicts of his composition, Titus is said to have written Greek poems and tragedies. The chief authorities for his life are Suetonius, Dion Cassius, and Tacitus.

TITUS, a companion and fellow laborer of the apostle Paul. He was a Greek, but we know not from what country. He was one of those persons sent from Antioch to Jerusalem to consult the apostles, and it was not judged necessary that he should be circumcised. He accompanied the apostle on his journey to Jerusalem, was his agent at Corinth and in Dalmatia, and was left behind with ecclesiastical commissions upon the island of Crete. According to Eusebius, Jerome, Theodoret, and the ecclesiastical tradition in general, he was the first bishop of Crete.

TITUS, EPISTLE TO, a canonical book of the New Testament, addressed by the apostle Paul to his disciple Titus. This and the two epistles to Timothy form the pastoral letters of the apostle, all of which have so many points in common that their authenticity has been generally attacked and defended simultaneously. (See TIMOTHY, EPISTLES TO.) The date of the Epistle to Titus has been the subject of much dispute, some fixing it as early as A. D. 52, others as late as 65, others at various intermediate years. The apostle furnishes Titus, whom he had left behind in Crete, with rules of conduct, especially in regard to the appointment of elders (i. 5-9), and warns him against certain false teachers (i. 10-16). He then describes the virtues becoming all classes, ages, and both sexes (ch. ii.), and inculcates obedience to civil rulers, moderation, gentleness, and avoidance of all idle speculations (ch. iii.).

TIVOLI (anc. *Tibur*), a town of central Italy, Papal States, situated on the left bank of the Teverone (anc. *Anio*), on the slope of Monte Ripoli, at an elevation of 850 feet above the sea, 18 m. E. N. E. from Rome; pop. 6,328. The streets are steep and narrow, and the houses generally indifferently built. It has

a handsome cathedral and several churches. The place is very rich in remains of antiquity. The temple of the Tiburtine sibyl is a beautiful circular building surrounded with Corinthian columns, and adjoining it is the temple of Vesta, now used as a Christian church. There are also remains of baths, bridges, several villas, and of a vast palace commenced by Hadrian. The climate is not considered good, and a great amount of crime prevails among the inhabitants. The manufactures and trade are of little importance. The Teverone forms a series of cascades in the neighborhood of the town, which are a great source of attraction.—Tibur is said to have been founded by the Siculi long anterior to the building of Rome, and to have been afterward colonized by Theban Greeks before the Trojan war. It possessed a small territory, with Empulum, Sasula, and other towns. It is mentioned by Pliny as one of the Sabine towns. The Tiburtines and Romans were at enmity, and the former aided the Gauls in their invasion of Rome in 361 B. C. This brought on a war between them which lasted several years, until in 348 the Tiburtines submitted. A few years later they joined the Latin league against Rome, and after its overthrow united with the Prænestini and Veliterni; but in 385 the consul L. Furius Camillus put them to rout under the walls of Pedum, and Tibur was treated with great severity, but remained nominally independent and a place of asylum for Roman fugitives till the end of the republic. Here Syphax died and Zenobia passed her captivity. The temple of Hercules, for whose worship Tibur was famous, was excepting that of Fortune at Præneste, the most remarkable in the neighborhood of Rome. Many Romans had magnificent villas here in the later period of the republic and under the empire.

TLASCALA, or TLAXCALA (Aztec, "land of bread"), a territory of Mexico, bounded W. by the state of Mexico, and on all other sides by that of Puebla; area, 1,918 sq. m.; pop. in 1857, 90,158. It received its name from its great fertility in maize.—TLASCALA, the capital, is situated between two mountains on the Rio Papagallo, 10 m. N. from the city of Puebla, and 70 m. E. by S. from Mexico; pop. in 1850, 8,468. It has a cathedral, a state house, an old bishop's palace, and a few other buildings of good architecture, among which is the oldest Franciscan convent in Mexico. In the surrounding country remains of the old Mexican architecture and fortifications still exist.—The Tlascalans belonged to the same family as the Aztecs, and formed at the time of the invasion of Cortes a powerful little republic, in which something like the feudal system was established. Although its territorial limits amounted only to 10 leagues in length by 15 in breadth, it successfully resisted all efforts of surrounding tribes and even of the Mexican monarchy for its subjugation. In 1519 the Tlascalans at first resisted the march of Cortes, but, after

having been defeated in several engagements, formed an alliance with him, and received from him a kind of independent existence under Spanish rule, the caïque being immediately subject to the governor of New Spain. The city is said to have numbered at the time of the invasion about 20,000 families, and Sept. 28, the day of Cortes's entrance, is still celebrated by the inhabitants as a day of jubilee. After the revolution Tlascala, being too small to form an independent state, was made a territory.

TLEMOEN, or TLEMOEN, a town in Algeria, province of Oran, situated on elevated ground 18 m. S. W. from Oran; pop. about 10,000. It is an ancient place, with narrow streets, and brick or stone houses seldom more than one story high. The citadel is a very large building, and there are many interesting remains of Roman origin. Iron, Morocco leather, carpets, and woollen, linen, and cotton goods are manufactured. A considerable trade is carried on with Morocco and the desert. Tlemcen was once the capital of a kingdom and a place of importance; but the inhabitants having revolted in 1670, the dey of Algiers laid it in ruins. The French took possession of it in 1836, but, in consequence of a treaty between them and Abd el Kader, they evacuated it the following year. It was again taken by them in 1841.

TOAD, the common name of a well known family of anurous or tailless batrachians, the general character and anatomy of which have been described under FROG, and AMPHIBIA. The *bufonidae*, which comprise the common toads, have a well developed tongue, jaws rather sharp at the edge but without teeth, thick and heavy body, and skin more or less covered with glandular warts which secrete an acrid fluid; the hind legs are but little longer than the anterior, so that they cannot make the long leaps of the frogs. According to Agassiz, the toads should rank higher than the frogs, from their more terrestrial habits; the embryonic web, which still unites the fingers of the frog, disappears in the toad, and the cutaneous glands of the skin do not exist in frogs. Toads, like frogs, absorb moisture by the skin, which is cast at intervals, coming off in lateral plates which are swallowed by the animal at a gulp; the skin feels hard to the touch, and, according to Mr. Rainey ("Microscopic Journal," 1855), contains a layer of earthy matter under the dermis effervescing with acids, considered by him the analogue of what becomes continuous hard dermal skeleton in the testudinate. Like frogs, they have also a large sac resembling a bladder, often found filled with pure water, in no way connected with the kidneys, but formed of the allantois, serving as a reservoir of water and aiding in respiration, its walls being highly vascular. The acrid fluid of the skin may be pressed out from two eminences like split beans just behind the head; it comes forth in a jet, and will make the eyes smart severely if it touch them. The void bone being absent, the root of the

tongue is attached anteriorly in the concavity formed by the branches of the lower jaw, the free extremity pointing backward when at rest; it is capable of protrusion in a reversed position so rapidly that the eye cannot follow it. From their ugly form and disgusting appearance they have always been despised and persecuted, though they are really not only inoffensive but of great service to man in destroying noxious insects and larvæ; they usually lie hid during the day, but come out at dusk in woods, fields, and gardens, in search of food, and are not unfrequently found in cellars and dark places about houses; their metamorphoses are of the same character as those described under FROG; they live out of the water except during the breeding season in March or April; during winter they remain torpid in holes and crevices, under stones, stumps, &c.; they lay a great number of eggs united into long strings, enclosed in a gelatinous substance, generally 2, which the male draws out with his hind feet. The species are less numerous than in the terrestrial and tree frogs; they are found in both hemispheres, but unequally distributed, being most abundant in America, and least so in Europe, which has not a single species peculiar to it, both the common toad and the natterjack occurring also in Africa and Asia; they are more abundant in Asia than in Africa, and only one is described in Australia; Duméril and Bibron recognize only 35 species of *bufonidae*.—In the genus *bufo* (Laur.) the tongue is oblong, free posteriorly; anterior limbs 4-toed and free, the posterior 5-toed and semi-palmated; the tuberosity behind each eye, above the tympanum, porous and cushion-shaped; head obtuse in front, the upper jaw descending directly downward so that the intermaxillaries do not project in front of the cranium. The common European toad or paddock (*B. vulgaris*, Laur.), the *crapaud* of the French, is 8 to 8½ inches long, of a lurid brownish gray, with reddish brown tubercles and a blackish stripe externally or along the glands on the sides of the head; the iris red or golden; the body thick and much inflated. It feeds on insects and worms of all kinds, but will touch only a living and a moving prey; it remains motionless, with eyes fixed on its intended victim till it comes within reach of its tongue, which is darted out with extreme rapidity and accuracy; when it seizes a worm, it pushes it into the mouth with the fore feet till all disappears, and the animal is swallowed whole. Its motions are by a kind of crawl; when alarmed it stops and swells out the body, and sometimes makes short and awkward leaps. The eggs are in a double series, 8 or 4 feet long and ¼ of an inch thick, and are laid in the spring 2 or 3 weeks later than those of the frog, the young being fully developed by the last of summer; they are smaller and blacker in all their stages than the young of the frog. Small toads of this and the common North American species are often

found in places where they could not have gone through the usual stages of tadpole existence, as in gardens and cellars where they could neither have had access to water nor have been introduced from without; the gills must have disappeared shortly after birth, if they ever existed; they appear to have the power of prematurely assuming the functional conditions of terrestrial animals when circumstances demand it; a similar rapid metamorphosis is observed as a rule in the Surinam toad mentioned below. For details on this subject, see "Annals and Magazine of Natural History," vol. xi. (London, 1858). The toad has been regarded as venomous in almost all countries and ages, its saliva, bite, cutaneous and watery secretion, and even its breath and glance, being supposed to be poisonous and more or less maleficent; the acrid exudation from the skin is sufficient to produce a painful irritation on a tender skin or a wounded mucous membrane; though it will make a dog quickly drop a toad from its mouth, it has no effect when introduced into the circulation; it not only serves thus for the protection of the animal, but is probably partly excrementitious, and assists the lungs in freeing the blood of carbon. Space will not permit more than an allusion here to the strange stories and superstitions connected with the toad; venomous and malicious as it was believed to be by the ancients, "the precious jewel in its head" was considered its redeeming quality; this jewel was not its bright and beautiful eyes, as hinted at by Shakespeare, but the bufonite or toadstone, supposed to possess wonderful medical and magical powers, and now known to be a palatal tooth of the fossil ganoid fish *pycnodus*. It has always been made a favorite companion for sorcerers and witches, and an ever present article in their magic compounds; it was the first ingredient thrown into the witches' caldron in "Macbeth." The toad has been known to live 85 or 40 years, and it is thought to attain a considerably greater age; it has been so far domesticated as to come and feed from its master's hand, and seems capable of a real attachment to man. From their well known fondness for insects, toads make excellent traps for the entomologist, who may thus procure rare and otherwise unattainable beetles and nocturnal species, which they can be made to disgorge without difficulty; intelligent gardeners often put them into hot-houses to destroy ants and other insects and larvæ injurious to choice plants. Like many other reptiles, the toad can live a considerable time without food and with a very small supply of air; but the alleged instances of their having been found imbedded in solid stone or the heart of a tree, with no possible communication with the external world, have no doubt arisen from errors of observation; though much remains unexplained about the facts upon which this popular belief is based, and though toads have been taken from places where it seemed impossible that they could have obtained food, air, or

moisture, it cannot be admitted that they have been hermetically sealed; with Mr. Thomas Bell it may be said: "To believe that a toad, enclosed within a mass of clay, or other similar substance, shall exist wholly without air or food for hundreds of years, and at length be liberated alive and capable of crawling, on the breaking up of the matrix now become a solid rock, is certainly a demand upon our credulity which few would be ready to answer." Dr. Buckland's experiments in 1835, in connection with the so called antediluvian toads, show that these animals cannot usually survive a long time, not even a year, deprived of air and food; see "Curiosities of Natural History," by his son Francis T. Buckland, 1st series, pp. 74-86 (London, 1859).—The other European species is the natterjack, mephitic, or green toad (*B. calamita*, Laur.); it is smaller, not 3 inches long, of a light yellowish brown color clouded with dull olive, and with a bright yellow stripe along the middle of the back; under parts yellowish with black spots, and the legs with black bands; iris yellowish green; it is less timid and the eyes more prominent; the hind legs are shorter and the toes less palmated, indicating more terrestrial habits; it is less common, more active, and frequents drier places; it is found throughout Europe, and in Asia and N. Africa.—The common American toad (*B. americanus*, Le Conte) is 2½ to 3 inches long, with short, thick, and bloated warty body; anterior limbs large, posterior short with a spade-like process at root of 1st toe, described as a rudimentary 6th toe by some writers; the jaws entire, and the eyes large and brilliant. It has a longitudinal line of dirty white from the occiput to the vent, on each side several spots of various colors, size, and shape, and a row of black and whitish ones extending to the hind legs; lower parts granulated and dirty yellowish white; anterior limbs dusky above with small white spots, the posterior ashy with blotches and bands of black. The head is smaller than in the European toad, the body less bloated, and the movements more active, yet they are representative species. In the breeding season toads and frogs do not generally assemble in the same pond; this species has been found on sandy shores overgrown with beach grass and in salt marshes; it is met with from Maine and Canada to the Mississippi valley; its note is a prolonged trill, continued by day and night, not unpleasant when the concert is at a considerable distance; it has been rendered so tame as to take flies from the hand. The Carolina toad (*B. lentiginosus*, Shaw) is 3 inches long, warty above, dusky brown with a tinge of yellow; below granulated, dirty yellowish white; head and mouth very large; it is timid and gentle, and fond of ants and fireflies; the males have a large gular sac, and are very noisy in the breeding season; it is found from S. Virginia to Florida, and along the gulf of Mexico. The marine toad of South America (*B. marinus*, Gray) is the largest of the family, 8

Quercus L.

to 10 inches long without the legs; it is ash gray, irregularly spotted with brownish, and with large warts.—There are several toad-like batrachians, generally arranged by modern herpetologists in the frog family, of which two may be mentioned here. The accoucheur toad (*B. obstetricans*, Laur.; genus *alytes*, Wagler) is common in the vicinity of Paris, in France, and in S. Germany; the males not only assist the females in the exolution of the eggs (which are yellow), but afterward attach them to their hind legs by small pedicles; the young are developed under ground in the femoral region until they reach the tadpole state, when the males enter the water and the larvae escape. In the genus *scaphiopus* (Holbrook) the body is short and thick, the head short, with teeth in the upper jaw and palate, and the tympanum distinct; posterior limbs short and stout, the leg shorter than the thigh, and a horny spade-like process in the place of a 6th toe; though generally ranked with the frog family, the form is toad-like; eyes large and prominent, with the iris golden and divided into 4 parts by 2 black lines; the anterior limbs long. The only species, *S. solitarius* (Holbr.), is between 2 and 3 inches long, olive and somewhat warty on the back, with 2 lines of pale yellow from the orbits to the vent; beneath yellowish white. It resembles the toads in its nocturnal, terrestrial, and subterranean habits, living in holes dug by itself, and seizing insects which fall in; its motions are sluggish, and it appears in the evening or after long continued rains; the males have a vocal sac under the throat; it is found from Massachusetts to Georgia. It is solitary except during the breeding season in early spring, when it takes to the water in considerable numbers; the eggs are laid from the last of April to the middle of July, are smaller and darker than in the common toad, and placed commonly around a spear of grass; as in the frogs and toads, they are frequently destroyed by a parasitic fungus. Swimming is performed by alternate strokes, as in the turtles, and their excavations are made by pushing out the hind feet laterally, by which they rapidly get under ground, the body being thrust backward as fast as the hole is formed; the pelvis is very loosely articulated to the sacrum, and moves freely backward and forward upon it.—The family *pipida* constitute the group of *phrynglosses*, so named from having no tongue, as distinguished from the *phaneroglosses*, in which this organ exists; the tympanum is concealed, and its cavity communicates with the mouth by a single opening in the middle of the posterior part of the palate; the head is triangular, and the small eyes are low and near the mouth; the body is broad and thick, the hind legs very powerful and large, and the toes united by a complete and full web. The family contains only 2 genera, *pipa* (Laur.) and *dactylethra* (Ouv.), each with a single species. In *pipa* there are no teeth, and the last joint of the slender anterior toes is divided into 4

parts. In *dactylethra* the upper jaw has small pointed teeth, the tongue is at the back of the mouth, and some of the hind toes have (alone among batrachians) hoof-like claws; the anterior legs are small and slender; the *D. Capensis* (Ouv.) is found at the Cape of Good Hope and on the Mozambique coast. The Surinam toad (*P. Americana*, Laur.) has a remarkable and anomalous mode of reproduction; the eggs do not escape into the water, but are received by the male, who deposits them on the back of the female and there impregnates them (some authors say that impregnation takes place before the deposition of the eggs on the back of the female); the skin becomes thickened between them, rises and partly invests each egg in a sac or pouch, covered by a thin operculum of dried gelatinous matter, probably a portion of that which originally surrounded the egg; the young go through the usual changes in the dorsal pouches, and emerge perfect toads; the yolk is of large size; the external branchiæ disappear at a very early period; the tail is fully formed in the embryo, but is absorbed before it leaves the egg; the embryo at this stage is larger than the original egg, so that it must have absorbed something from the pouch of the parent. This animal is commonly found in the dark corners of houses in Guiana and Surinam, and, though exceedingly disgusting in appearance, is said to be eaten by the natives.

TOAD FISH, a spiny-rayed fish of the *lophius* family, and genus *batrachus* (Bloch.), so named from its large head, wide gape, usually naked skin, and disgusting appearance; it is also called frog fish and oyster fish. The head is flattened and wider than the body; teeth conical, small and crowded on the intermaxillaries, larger on the lower jaw, palate, and vomer; operculum small and spiny; head, lips, and cheeks provided with numerous fleshy appendages; lower jaw the longest; 1st dorsal short, with 8 spinous rays almost concealed in the skin; 2d dorsal and anal low, soft, and long; ventrals under the throat, narrow, with 8 rays; pectorals on short arms of 5 carpal bones; 4th branchial arch without gills; body generally scaleless; no pyloric cæca; air bladder deeply forked anteriorly, attached to the vertebrae by slender ligaments, and muscular on the sides. They hide in the sand and mud of salt water, and occur in both hemispheres, preying on fish. There are more than a dozen species, of which one of the best known is the grunting toad fish (*B. grunniens*, Bloch), found in the seas of the East Indies; the skin is naked, smooth, soft and spongy; the head and jaws with numerous cutaneous appendages; the color is brownish above, marbled with darker, below white, fins white with brown bands; it is 8 to 13 inches long, and is said to be eaten at Bombay; it received its specific name from its making a grunting noise like a pig, from the expulsion of air by the muscular air bladder through the mouth.—The common American toad fish (*B. tau*, De Kay) is much like the

East Indian, with half a dozen more rays in the 2d dorsal and anal, stronger teeth, more prominent dorsal spines, and rather darker colors; it is 8 inches to a foot long, of a light brown color, marbled with black, and the fins with black lines; the body is covered with a copious viscid secretion; the mouth very large, and the chin and cheeks with numerous fleshy appendages. It is found along the Atlantic coast from Maine to the gulf of Mexico and the West Indies, on the New England coast usually in ponds and lagoons connected with the sea, in muddy shoal water, or under eel grass and stones; it is sometimes taken in winter by the fishermen spearing eels through the ice; where it is abundant, as in some places along the New Jersey coast, it is a great pest from its taking the bait intended for more valuable fish; it lives a considerable time out of the water. It is fond of lurking in holes in the sand, watching for prey like a dog in a kennel, and snapping at any unwary fish coming within reach of its wide jaws; in the summer it may be seen guarding its eggs or young, the latter being found adhering to the under surface of stones by a disk at the end of the yolk sac, and afterward by the ventral fins. The disgusting appearance of this fish, its slimy body, goggle eyes, and immense mouth, have generally prevented the use of its flesh as food, though it is said to be delicate, palatable, and wholesome; it is a savage biter, and capable of inflicting severe wounds. The specific name, which was conferred by Linnæus, though he referred the fish to a wrong family, is derived from a character common to many other species, and only observable in dead and dried specimens; in these the bones of the upper surface of the skull present a transverse and longitudinal ridge united like the letter T (Gr. *tau*). Other species are found in the Indian and African seas, and some of larger size and with soft scales on the Brazilian coast.

TOBACCO, the common name of several species of plants of the genus *nicotiana*, natural order *solanaceæ*, and also of the dried leaves of the plants. The order is remarkable for the number of genera belonging to it of plants possessing powerful narcotic poisonous properties, and at the same time of useful edible plants. Of the former kind may be named the belladonna or deadly nightshade, the stramonium or thorn apple, the hyoscyamus or henbane, &c.; and of the latter the tomato and the potato, which last also affords the poisonous substance solanine. The name tobacco is supposed to be derived from the Indian *tabaco*, given by the Caribs to the pipe in which they smoked the plant. Others derive it from Tabasco, a province of Mexico; others from the island of Tobago, one of the Caribbees; and others from Tabasco in the gulf of Florida. The name of the genus is derived from that of the French ambassador to Portugal, Jean Nicot, who brought some tobacco in 1560 from Lisbon to France. Several species of the plant are recognized by botanists, but most of the tobacco of

commerce is obtained from the *nicotiana tabacum*, the common Virginia or sweet-scented tobacco. The plant is an annual, growing 3 to 7 or 8 feet high, with an erect, round, hairy, viscid stem, and a large fibrous root. It bears numerous very large leaves of a pale green color, sessile, ovate lanceolate and pointed in form, which come out alternately from 2 to 3 inches apart. Those near the bottom are sometimes 2 feet long and 6 inches broad. The flowers grow in loose panicles at the extremities of the stalks, and the calyx is bell-shaped and divided at its summit into 5 pointed segments. The tube of the corolla expands at the top into an oblong cup terminating in a 5-lobed, plaited, rose-colored border. The pistil consists of an oval germ, a slender style longer than the stamens, and a cleft stigma. The flowers are succeeded by capsules of 2 cells opening at the summit and containing numerous kidney-shaped seeds. The plant was unknown to the Europeans until the discovery of the American continent, when it was first noticed by sailors sent ashore by Columbus in Cuba. They found to their astonishment the natives puffing smoke from their mouths and noses, which they afterward learned was derived from the combustion of the dried leaves of this plant. The smoke was inhaled through a hollow cane, one end of which was introduced into the mouth, or in case of the cane being forked, the forked ends were inserted in the nostrils, and the other was applied to the burning leaves. As other portions of America were discovered, tobacco was very generally met with, and appears to have been used in various ways by all the tribes from the N. W. coast to Patagonia. Garcilasso speaks of the ancient Peruvians as using it only for medicinal purposes in the form of snuff. The Aztecs in Mexico, according to Bernal Diaz, used pipes of a varnished and richly gilt wood, and mingled with the intoxicating tobacco the liquidambar and various aromatic herbs. They are also spoken of by Sahagun in his "History of New Spain" as using the leaves rolled into cigars, which they ignited and smoked in tubes of tortoise shell or silver. The use of the pulverized dried leaf or snuff was noticed by Roman Pane, a friar who accompanied Columbus on his second voyage. The natives, he found, took it as a purgative medicine, snuffing it up through hollow canes. Thus all the modes in which the plant is now used appear to have been in common practice with the ancient American races. Its use is traced back to still more remote periods in the pipes found in the ancient mounds and other monuments of unknown races, that inhabited this continent before the Indian tribes. (See PIPE, TOBACCO.) The history and uses of the plant are further noticed in the article CIGAR.—Among the many species and varieties of the tobacco plant, several are worthy of special mention. The plant which yields the "large-leaved" or "Orinoco tobacco" is probably merely a variety of the *N. tabacum*,

though it has been named by Miller *N. latissima*, and by Sprengel *N. macrophylla*; the large Havana cigars are supposed to be made of its leaves. The *N. rustica*, or "common green tobacco," is the species most cultivated in Europe and some parts of Asia and Africa, where also it grows wild, and is said to be that originally introduced into Europe from America. It furnishes the tobacco of Salonica, and the Turkish tobacco grown on the coasts of the Mediterranean, which is so highly valued in India. In England it is cultivated in gardens, and is used by gardeners to destroy insects. Its leaves are petiolate, ovate, and quite entire. The celebrated Shiraz or Persian tobacco is produced by the *N. Persica* (Lindl.). The small Havana cigars are said to be made of the leaves of *N. repanda* (Willd.). The *N. fruticosa* is supposed to be a native of China, and to have been cultivated there in ancient times. The *N. quadrivalvis* (Pursh) affords tobacco of excellent quality to the Indians of the Missouri and Cumberland rivers; the dried flowers are preferred to the leaves. The *N. nana* and the *N. multivalvis* are also plants of the extreme western territories. The calyx of the latter, which is very fetid, is preferred to any other part.—The varieties of tobacco known in commerce are designated by the names of the districts where they are produced. The principal varieties of the United States are the Virginia, Kentucky, Maryland, Missouri, and Ohio. The first is the strongest kind of tobacco, its leaves of a deep brown and tough, and is better adapted for chewing, for snuff, and for smoking in pipes, than for cigars. The other varieties are generally of a paler color, and of various degrees of strength. The tobacco raised in Connecticut and Massachusetts is alluded to in the article CIGAR, as used for the outer covering of cigars, and the same article names the varieties best adapted for these. The Levant tobaccos are mild and pleasant, and highly valued. The Turkish variety, of which the Latakia is most celebrated, is exported in broad and separate leaves of a bright yellow color. Manila tobacco, grown in Luzon, is dark-colored, and is largely used in the manufacture of cheroots, as cigars are termed in the East.—Of the analyses that have been made of tobacco, the following are the most important. The first by Vauquelin is given in the *Annales de chimie*, vol. lxi. p. 139, and presents the following ingredients: an acrid volatile principle (nicotine); albumen; red matter, soluble in alcohol and water; acetic acid; supermalate of lime; chlorophyl; nitrate of potash and chloride of potassium; sal ammoniac; and water. The next is the analysis of the tobacco leaf by Dr. Conwell, of Philadelphia, given in the "American Journal of Science," vol. xvii. p. 369: gum; mucilage, soluble in both water and alcohol; tannin; gallic acid; chlorophyl; green pulverulent matter, soluble in boiling water; yellow oil having the odor, taste, and poisonous properties of tobacco; pale yellow

resin (large quantity); nicotine; a substance analogous to morphia; an orange-red coloring matter; and nicotianine. The German chemists Posselt and Reinmann obtained the following results, quoted by Berzelius in his *Traité de chimie*, and by Gmelin in his *Handbuch der Chemie*, vol. ii. p. 1803:

Nicotine.....	0.060
Concrete volatile oil.....	0.010
Bitter extractive.....	2.870
Gum with malate of lime.....	1.740
Chlorophyl.....	0.267
Albumen and gluten.....	1.808
Malic acid.....	0.510
Lignine and a trace of starch.....	4.969
Salts (sulphate, nitrate, and malate of potash, chloride of potassium, phosphate and malate of lime, and malate of ammonia).....	0.734
Silica.....	0.088
Water.....	88.380
Total.....	100.886

The active principles of the plant reside in the alkaloid nicotine or nicotia, and the nicotianine. The former was first separated in a pure state by Messrs. Henry and Boutron, that obtained by the other chemists being an aqueous solution of the alkaline principle in connection with ammonia. (See NICOTIA.) The strongest Virginia and Kentucky tobaccos contain from 6 to 7 per cent. of it, while some of the milder kinds used for cigars contain only about 2 per cent. Nicotianine is the concrete volatile oil of tobacco, or tobacco camphor, obtained by distillation. Six pounds of the leaves yield only about 11 grains of the oil. It is a fatty substance, having the smell of tobacco smoke and a bitter taste. It is volatilized by heat, and is insoluble in water and dilute acids, but dissolves in alcohol, ether, and solution of potash. An empyreumatic oil obtained when the distillation is conducted at a temperature above 212° contains nicotia, and is a most virulent poison. It is of a dark brown color, an acrid taste, and a smell like that of old tobacco pipes. This oil, which cannot be distinguished from that of foxglove, has been detected in tobacco smoke together with nicotianine, nicotia, salts of ammonia, and other volatile products. The ash of tobacco leaves amounts to about $\frac{1}{3}$ to $\frac{1}{2}$ of the entire weight, and consists chiefly of carbonates of lime and magnesia, chloride of potassium, and sulphate of potash.—The medicinal effects of tobacco upon the system are very marked, whether it is taken internally or applied externally. In small quantities, taken by either of the methods in which it is commonly used, as smoking, chewing, or snuffing the pulverized dry leaf, it acts as a sedative narcotic, calming mental and bodily restlessness, and producing a state of languor or repose most agreeable to those accustomed to its use. In larger quantities, or with those unaccustomed to it, it causes giddiness, faintness, nausea, vomiting, and purging, with great debility. As the nausea continues with severe retching, the skin becomes cold and clammy, the muscles relaxed, the pulse feeble, and fainting and sometimes convulsions ensue, terminating in death. Its power of causing relaxation of the muscular

system is greater than that of digitalis, and has been taken advantage of in surgical treatment, as by Dr. Physick in a case of obstinate and long continued dislocation of the jaw, the desired effect being produced by smoking, to which the patient was unaccustomed. It is also applied in the form of infusions and cataplasms to relieve various spasmodic affections, and its use generally in medicine is in external applications, the nausea it occasions almost wholly preventing its exhibition internally. It is recommended in articular gout, rheumatism, and neuralgia; and the toothache is often relieved by smoking a cigar. In various cutaneous affections, as tinea capitis, psora, &c., it has proved highly beneficial. The application of the infusion, or even of the leaves, or of powdered tobacco, to surfaces deprived of the cuticle, is not without danger, and has sometimes been attended with fatal effects; these have even followed the inhalation of the smoke. The powerfully nauseating effects of tobacco suggest its use as an emetic; it is however rarely resorted to for this purpose, though in extreme cases, as of sudden poisoning, it might be found serviceable, where no other emetic is at hand. Entirely different opinions have been entertained by the most respectable medical authorities as to the effects of tobacco upon the system, whether beneficial or hurtful, as it is commonly used; and ever since the early introduction of tobacco many have earnestly condemned it for its supposed universally injurious qualities. Its use nevertheless has been constantly increasing, and multitudes among all nations depend upon it daily, suffering extremely if deprived of it for a time. Its universal distribution throughout almost all climates and countries, taken in connection with the strong passion soon acquired for its use, would seem to imply that the plant exercises some important influence upon the human system; still it is not apparent what benefit is conferred upon generations of recent times, which those were deprived of that were ignorant of its use. It does not appear to affect in any way the duration of human life, except occasionally when used to great excess. To some persons the use of tobacco is repugnant, and by such it is naturally condemned and avoided.—Tobacco is successfully cultivated throughout a wide range of latitude. Excellent varieties are produced in the equatorial regions, and in the United States its limits are not quite reached at the borders of Canada; in all the states it is cultivated to some extent. In England, as already mentioned, it is cultivated in gardens, and there is no question but it would be an important crop, if it were not for the severe restrictions imposed upon its growth for manufacturing purposes. It has been even raised in Scotland during the interruptions by foreign wars of the trade with the colonies. The plant requires a deep, rich, mellow soil or sandy loam, and thrives best on the south side of gentle slopes and places protected by woods or shrubbery.

According to the best practice in the middle states, the seed, amounting to a gill for every 10 square yards, is mixed with about a quart of plaster or sifted ashes and sown regularly in well prepared beds. This may be done in the winter, but the best time is from the 10th to the 20th of March. The greatest care is taken to prevent the growth of weeds, and to root them out by hand while the plants are young. It is recommended, every week after the plants are up, to scatter over them broadcast a compost of ashes, plaster, soot, salt, and pulverized sulphur, with the view of invigorating them and preventing the ravages of the fly. In April, when the plants are of good size for transplanting, they are removed to other beds prepared with great care, and marked off by a small plough in furrows crossing each other at right angles, at distances of 2½ to 3 feet apart. In each of these the workman makes a hole with a finger of the right hand, and introduces the root of one of the plants. In 8 or 4 days the surface is lightly hoed, the weeds removed, and a little plaster and ashes is added to each plant; and in a week afterward a small plough is run twice through the rows. After this the "tobacco cultivator" or shovel is run through once in a week or 10 days to keep the ground open and free from weeds; and when the plants are too large for this process, the ground is once well hoed over and levelled. As soon as the blossoms are fairly formed, the tops are cut off down to the leaves that are 6 inches long, or still lower if the season is late. A number of the best plants should be reserved for seed, 100 being sufficient for a crop of 40,000 lbs. In two weeks after "topping" the plants are fit for cutting, though they may stand longer without injury. Until the leaves are cut and housed, the crop still requires great care to protect it from frost, to remove suckers that sprout from the base of each leaf, and to destroy worms which would otherwise devour the plants. The bottom or "ground leaves" are cut off and taken in before they become dry. The killing of the worms is a work of great labor, it being necessary to examine each plant, going over the whole field as far as practicable every morning and evening in order to break the eggs and kill such worms as may be found. A previous brood or "glut" of worms appears in the early part of the season, and to destroy these flocks of turkeys are let into the field, which devour the worms with great avidity, and kill many more than they can eat, seemingly enjoying the sport. When the leaves begin to turn yellow, the stalks are cut off close to the ground, where they are left for a short time to "fall" or wither before they are taken to the tobacco house. Here they are hung upon pegs or spears run through the stalks and left to dry. Sometimes the stalks are split with a knife from the top to within a few inches of the bottom before they are cut down for housing, when they are hung upon sticks which are suspended upon the joists of the tobacco house.

12 or 15 inches apart. After the leaves have turned yellow, the drying is sometimes hastened by fires upon the floor of the house; but the process is better effected by the admission of plenty of air in dry weather in roomy houses provided with windows and doors, by the closing of which rain and dampness are excluded. When the tobacco is well dried and cured, the leaves are stripped from the stalk in mild damp weather, the leafstalks then becoming soft and pliant. The stripping, when systematically performed, employs several persons called "cullers" in succession. The first pulls off the defective bottom and worm-eaten leaves, and throws the plant to the next, who strips off all the bright leaves, and passes it to the third, who removes the rest, which are known as the "dull" leaves; and each as he accumulates leaves enough ties them in bundles of $\frac{1}{2}$ or $\frac{3}{4}$ of a pound in each, using one of the leaves as a wrapping for each bundle, and tucking the end in the middle of the bundle in order to confine it. The next operation is what is called "bulking" the tobacco, which is the final drying applied to each of the sorted kinds separately. The bundles are laid up in piles, generally between two logs laid parallel to each other and about 80 inches apart, the space between being filled with sticks to keep the bundles from the dampness of the ground. Upon these the bundles are smoothly laid with care crosswise, the butts outside and the tops lapping over each other in the middle. When raised to a convenient height, the bulk is covered with a few sticks to keep it in place. If found to heat from incipient fermentation, the bundles are to be taken down and laid again more loosely than before; and it may be necessary to hang them up in the house to become properly dried or "conditioned" for packing. When so dry that the bundles crack under pressure, advantage must be taken of the first damp weather, when the leaves become somewhat pliable, to pile them closely in larger and higher bulks under considerable pressure, in which condition they may safely remain for any time before packing in hogsheads. The legal dimensions of the tobacco hogshead in Maryland are 40 inches across the head and 52 inches deep, and the capacity is 800 lbs.; that of the hogshead of Virginia, Missouri, and Kentucky is 1,200 lbs., and of Ohio 750 lbs. The bundles are laid in uniformly in "courses" or layers, and are closely packed down by a man inside, who presses them with his knees and occasionally stamps upon them, with caution however not to break the bundles. Mechanical power is also applied at intervals, and continued several hours at a time, to compress the tobacco in the hogsheads. The filling of these completes the preparation of the leaf tobacco for the market. The production to the acre is usually from 600 to 700 lbs. According to the U. S. census returns for 1850, the product in Virginia averaged in that year 660 lbs; in Maryland, 650 lbs.; in Kentucky, 575 lbs.; in

Ohio, 730 lbs.; in Tennessee, 750 lbs.; in Missouri, 775 lbs. The total number of acres in cultivation throughout the country was 400,000, which at an average of 600 lbs. to the acre would produce 240,000,000 lbs. The gross value of the product for that year was estimated at \$13,982,686.—The tobacco packed in hogsheads is ready for transportation either to Europe or to the factories in the states in which it is converted into cigars, or into the forms of cut and roll tobacco for chewing and smoking in pipes, or into snuff. Of the European consumption of tobacco it is estimated that about $\frac{2}{3}$ are furnished by the United States; and of that consumed in France from $\frac{1}{4}$ to $\frac{3}{4}$ are from this country. This product is in request for chewing tobacco and snuff, while the milder sorts obtained from Cuba and from the interior countries of Europe are preferred for smoking. In many of the European countries the manufacture of tobacco is a very important business. In France the manufacture employs about 15,000 persons, who produce annually about 60,000,000 lbs. of manufactured articles of tobacco. The net profit realized by the state amounted in 1859 to 178,752,541 francs. In Holland the first class factories, of which the larger number are at Rotterdam and Amsterdam, are said to employ above a million of persons, the principal market for the products being in Germany. Large amounts are exported to Great Britain, notwithstanding the article is subject to a duty of 72 cts. per lb. and 5 per cent. additional, and there also gives employment to great numbers of operatives. Only 13 ports in England, 8 in Scotland, and 10 in Ireland are allowed to receive tobacco, and it must be brought by vessels of at least 120 tons. The casks as they are received are conveyed to the bonding warehouses, where every one is opened and its contents are examined. By taking out the head and loosening some of the staves, the whole hogshead is removed from the tobacco, and any injured portions are cut away by a powerful instrument, and the remainder is weighed and repacked. The duty is levied only on this portion, and the damaged is immediately consumed in a furnace on the premises. Taken to the factory, the bundles are dug out in masses with iron instruments, and being moistened with water (to which the French add $\frac{1}{4}$ its weight of sea salt, first dissolved in licorice juice in which a few figs have been boiled, together with bruised anise seeds, &c.), the bundles are easily separated from each other, and also the leaves. If the stalks have not been previously removed, this is now done by women or boys, who fold the leaf along the middle and strip out the midrib by a small instrument. The leaves may then be sorted according to their different qualities, the same plant affording leaves of different colors and flavors; and it is only by attention to this that certain manufacturers retain the reputation they have acquired for their peculiar products. To form

cut tobacco, the leaves are made up into large cakes, which are cut into shreds or filaments by the action of machines similar in principle to straw-cutters, and worked sometimes by horse power and sometimes by steam. The machines can be regulated to make finer or coarser filaments as desired. In this condition the tobacco is ready to be converted into the various forms for chewing or smoking purposes. The dark-colored leaves, made still darker by the liquoring process, produce the coarse variety called shag, and the better sorts are converted by spinning processes into cords variously folded or twisted, and distinguished by different names. The term "negro head" is applied to coarse rolls of this tobacco weighing 6 or 8 lbs. each. The variety known as "pigtail" is also a spun tobacco, the cord being but little larger than a pipe stem, and the leaves being flavored previous to spinning by the application of a certain sauce or sweet saline liquor, which gives to them a peculiar color and flavor. This variety is often covered with what are called robes, made of the largest and strongest leaves after the removal of the midrib. In the United States a great deal of tobacco, intended chiefly for home consumption, after being cut up, is made into flat cakes, which are moistened with molasses and powerfully compressed. These cakes are about 5 inches long and 1½ wide, and when closely packed in the strong oak boxes in which they are sent to market, they adhere together, forming a compact mass, from which the cakes are torn out only by the application of considerable force. This, known as plug or Cavendish tobacco, is in common use for chewing, and is smoked in pipes by those who are fond of tobacco of the strongest flavor.—The leaf stalks separated in the first manufacturing operation are preserved to be converted into snuff, and are used either alone or mixed with leaves. Some kinds of snuff are also made wholly from the leaves; and many varieties are formed from fanciful mixtures of tobaccos of different countries, with the addition of leaves of other plants, as of the rose, together with other ingredients, as rosewood dust, common salt, and various drugs. The tobacco is well dried previous to grinding, and this is sometimes carried so far as to give to the snuff the peculiar scorched flavor of the "high-dried" snuffs. The grinding is effected in mills of different sorts, one kind of which, much used for this and similar operations, is a form of the Chilian mill, described under that title; small mortars are also used, the pestles of which are kept rolling round by machinery. The subsequent sifting is also effected by machinery. Snuff is much more largely consumed in Great Britain than in the United States; but in the former country its use has considerably fallen off of late years, while that of cigars and of shag or cut tobacco is constantly increasing. The principal snuff factories are in London, Liverpool, Bristol, and Leeds in England; Glas-

gow and Edinburgh in Scotland; and Dublin and Cork in Ireland. The last produce the high-dried snuff, which is much esteemed in Ireland. In Scotland the rappee snuff is preferred, the so called Scotch snuff being used by women chiefly of the lower classes.—Next to the United States the principal tobacco-producing countries of the world are some of the West India islands and of the states of Central and South America, as Cuba, Hayti, Brazil, Peru, &c.; in the East Indies, Manila, Java, China, &c. Asia Minor, Egypt, Turkey, Greece, Hungary, the southern part of Russia, Holland, Belgium, all the states of Germany, many of the departments of France, Algeria, Corsica, and upper Savoy, are all somewhat noted for the culture of the plant. The total production of the world has been estimated as follows: Asia, 899,900,000 lbs.; Europe, 281,844,500; America, 248,280,500; Africa, 24,300,000; Australia, 714,000; making in all 995,039,000 lbs. The product and importations from the United States of some of the European countries are presented in the following table:

Countries.	Home product, lbs.	Importations from United States, lbs.
Austria { Hungary.....	66,000,000	2,945,000
{ Galicia, the Tyrol, and Venice }	11,000,000
Zollverein.....	55,000,000	7,390,000
Belgium.....	1,300,000	4,910,000
Holland.....	5,000,000	17,134,000
Bremen.....	26,053,000
Hamburg.....	2,000,000
Russia.....	25,000,000
Great Britain.....	24,208,000
France.....	44,000,000
Spain.....	7,534,000
Sardinia.....	3,311,000
Sweden and Norway.....	1,713,000
Portugal.....	393,000
Russia.....	8,180,000

The French manufacturers give the following characters to the tobaccos they employ: the Virginian, strong, very aromatic, and much esteemed for snuff; the Kentucky, strong, large-leaved, very choice; the Maryland, light, odoriferous, large-leaved, used exclusively for smoking in pipes; the Havana, unequalled for cigars; the Java, used for the same purpose, its odor like that of pepper; other tobaccos from the West Indies and Central and South America, used for cheap cigars. The tobaccos from the Levant are little esteemed. The Holland product has much strength, and is excellent for snuff mixed with weaker sorts. The Hungarian varieties are used for cigars and smoking tobaccos. Some of the French departments produce tobacco used exclusively for cigars, and other varieties used only for pipes. Some of the Algerian tobacco raised by the Arabs is equal to any obtained in America, but a large portion of the product from that country is of inferior quality.—TOBACCO TRADE. Tobacco, being an article of very general consumption, and yet not a necessity, has been selected by many of the European governments as a peculiarly appropriate commodity on which to raise a revenue. Some of these

governments, as France, Spain, Portugal, Sardinia, and Austria, make it a monopoly, either wholly managing its manufacture and sale, or allowing individuals to import and sell under heavy imposts and restrictions. In England the customs duty on all raw tobacco is 8s. (72 cts.) per lb. and 5 per cent. extra, making 8s. 1½d. or 75 cts. On snuff the duty is 6s. 8½d. per lb., and on cigars and manufactured tobacco 9s. 4½d. Notwithstanding this enormous tax, which on the raw tobacco amounts to 8 to 7 times the original cost of the article, the consumption is so great, that in the years 1857, 1858, and 1859 the revenue derived from this source amounted respectively to £5,258,481, £5,454,214, and £5,578,468; and the whole amount consumed in that country has been given at 29,737,561 lbs. per annum. The chief portion of the consumption is of shag or common roll tobacco, and the common kinds of snuff. In one of the principal London factories the daily production of cigars is only about 60 lbs., while that of cut tobacco is 2,000 lbs. The high cost of tobacco has led in England to extensive adulterations with a great variety of other leaves and other substances, the presence of which can generally be detected by the microscope. The following are among the articles most used: leaves of the rhubarb, dock, burdock, coltsfoot, beech, plantain, oak, and elm; pest earth, bran, saw dust, malt roots, meal of barley, oats, beans and peas, potato starch, and chicory leaves steeped in tar oil. The possession of any of these or of various other specified substances by a tobacco manufacturer renders him liable to a fine of £200. A work on "Tobacco and its Adulterations" was published in London in 1858, prepared by Henry P. Prescott, of the inland revenue department. The subject is also treated by Dr. Hassall in his "Adulterations Detected."—The production of tobacco in the several states and territories for the years named is given as follows in the census returns:

States and territories.	1840.—lbs.	1850.—lbs.	1860.—lbs.
Maine.....	30
New Hampshire.....	115	50	21,000
Vermont.....	585	12,000
Massachusetts.....	64,955	188,346	3,283,000
Rhode Island.....	817	1,000
Connecticut.....	471,637	1,367,624	6,000,000
New York.....	744	88,189	5,764,000
New Jersey.....	1,923	810	149,000

The annual export from the United States has been as follows for the years named:

Years.	Bales.	Cases.	Hhds.	Value.
1855.....	12,913	13,366	150,913	\$14,719,468
1856.....	17,779	9,384	116,968	12,931,848
1857.....	14,433	5,681	156,548	29,662,779
1858.....	12,640	4,841	197,670	17,009,767
1859.....	19,651	7,188	196,840	27,074,083
1860.....	17,617	15,086	167,374	15,906,547
Total....	95,925	55,445	917,907	\$110,597,485

The importations of tobacco into the United States are chiefly from Cuba, and $\frac{1}{2}$ of these are of cigars, the value of which is from \$8,000,000 to \$4,000,000 annually.—Among the publications upon tobacco, beside that of Prescott already referred to, may be named the treatise by Joubert, *Nouveau manuel du fabricant de tabac* (Paris, 1844); "The Uses and Abuses of Tobacco," by John Lizars, professor of surgery (Edinburgh; reprinted, Philadelphia, 1859); and "Tobacco, its History and Associations," by F. W. Fairholt (London, 1859).

TOBACCO PIPE: See PIPE.

TOBAGO, an island of the Windward group of the British West Indies, the N. point of which is in lat. 11° 25' N., long. 60° 32' W., 32 m. long by 12 broad; area, 97 sq. m.; pop. 13,027. Scarborough, on the S. W. side of the island, is the chief town. There are several good harbors on the N. side for vessels of about 150 tons, and a few also on the opposite side of the island. Tobago is a mass of rocks which rises abruptly on the N. E. side and descends toward the S. W., the most elevated part of which is about 900 feet above the sea. There are several small valleys, well watered by numerous streams. The productions consist of sugar, molasses, and rum. Tobago is not subject to hurricanes. It has a lieutenant-governor and local legislature. It was discovered by Columbus in 1496, and was ceded by France to Great Britain in 1763.

TOBIT, a book of the Old Testament in the Roman Catholic canon, but regarded as apocryphal by Jews and Protestants. It contains the history of a pious Jew of the tribe of Naphtali, living in exile at Nineveh. Being purveyor to the court of King Sennacherib, he became wealthy; but under Sennacherib he lost his position and his property, because he had buried Jews who had been executed. Having returned to Nineveh after the death of Sennacherib, he became blind; but he was cured by a fish which his son Tobias had brought home from a journey undertaken in company with the angel

Raphael. The Greek text and the Latin translation of Jerome, which was made from a Chaldaic text, considerably differ. The author is supposed to have been a Jew of Palestine, but his age cannot be ascertained. Among the best commentaries on the book are those of Fritzsche (Leipsic, 1858), Sengelmann (Hamburg, 1859), and Reusch (Freiburg, 1857).

TOBOLSK, a government of Western Siberia, bounded N. by the Arctic ocean, E. by Yeniseisk and Tomsk, S. by the Kirgheez territory, and W. by Archangel, Perm, and Orenburg; area, 557,516 sq. m.; pop. in 1856, 1,017,683. The sea coast is indented by several deep bays, and for about 250 m. inland the country is barren and sterile. To the W. Tobolsk is separated from Archangel by the Ural mountains. In the centre of the government there are forests of great extent containing much fine timber, while toward the S. the land affords good natural pasturage and is well suited for cultivation, but is interspersed with sterile steppes. The greater part of the government is drained by the Obi and its tributaries, the Irtysh, Ishim, Tobol, and others. There are many extensive lakes, in which, as well as the rivers, fish are very abundant. Different kinds of wild animals are numerous, more particularly those yielding valuable furs, and a large portion of the population are employed in hunting. The inhabitants are a mixture of Ostiaks, Samoyedes, Tunguses, and Russians, many of the last named being exiles, or descended from exiles. The mineral resources of the province have been but partially developed. Metals, glass, soap, and potash are manufactured. A large transit trade is carried on between the countries lying to the W., China, Bokhara, and Tartary. The principal towns, beside the capital, are Obdorsk, near the mouth of the Obi, Petropavlovsk, on the Ishim, and Omsk, on the Irtysh, formerly the capital of a government of the same name.—TOBOROK, the capital, is situated on the right bank of the Irtysh, at the confluence of the Tobol, in lat. 58° 12' N., long. 68° 20' E.; pop. about 20,000. Silk ribbons, reindeer and other skin dresses, soap, candles, and glass are manufactured; and the traffic between European Russia and China finds a centre here. Traders from Europe arrive with their goods in the spring, and in autumn their returning boats reach Tobolsk on their way to the W.; merchants from Tartary and Bokhara arrive about November and return home in spring.

TOCANTINS, a river of Brazil, formed by the Almas and Maranhão, which rise in the province of Goyaz and unite in lat. 14° S., long. 49° 15' W. After a course of about 1,000 m., in a general northerly direction, it falls into the estuary of Para, about 80 m. S. W. from Para. The Araguay, which joins it about lat. 6° S., is the most important tributary; and although it loses its name, it has a longer course to the junction and a greater volume of water than the Tocantins. The affluents next in importance are the Paraman, the Ma-

noel Alves Solobre, the Great Somno, and the Manoel Alves Septentrional, which join it from the E., and the Tucahunas and Teresa, from the W. The tide ascends about 800 m., and at its mouth the Tocantins is 8 m. wide.

TOCQUEVILLE, ALEXIS CHARLES HENRI OLÉREL DE, a French publicist and statesman, born in Paris, July 29, 1805, died at Cannes, April 15, 1859. After being admitted to the bar at Paris, he was appointed a judge in Versailles in 1826, and was promoted in 1830. The next year he was sent, in conjunction with Gustave de Beaumont, on a mission to the United States, to examine the penitentiary system; and a full report of their observations was published under the title *Du système pénitentiaire aux États-Unis* (8vo., 1832; translated into English by Francis Lieber, 8vo., Philadelphia, 1838). De Tocqueville had made use of the opportunity to acquaint himself thoroughly with the political and social institutions of the country, and wrote a philosophical work entitled *De la démocratie aux États-Unis* (2 vols. 8vo., Paris, 1835), which was extensively read, and rewarded in 1836 by a prize by the French institute, and in 1837 by his nomination to the academy of moral and political sciences, and in 1841 to the French academy. Being elected in 1839 to the chamber of deputies, he sat there among the most moderate members of the opposition, was in 1840 the reporter of a committee upon slavery, advocated the establishment in France of the American penitentiary system, and, while always ready to join in the improvements proposed by the ministry, was energetic in his denunciations against electoral corruption. He was one of those who foreboded the revolution of February. A member of the constituent assembly, he strongly opposed socialistic doctrines, and voted with the majority against ultra-democratic measures. He was appointed by Gen. Cavaignac to represent France in the diplomatic conferences held in Brussels upon the Italian affairs. On June 3, 1849, he became minister of foreign affairs, and strongly supported the French expedition to Rome, but, dissatisfied with the policy of President Louis Bonaparte, resigned his office before the end of the year, and sat again among the opposition. On Dec. 2, 1851, he was one of the deputies who met in the hall of the 10th arrondissement, and was arrested and incarcerated, but released in a few days. He now retired to private life, resumed his historical pursuits, and in 1856 published *L'ancien régime et la révolution* (8vo.; translated into English by J. Bonner, 12mo., New York, 1856). His *Œuvres et correspondances inédites* have been published, with a biographical notice by his friend G. de Beaumont (2 vols. 8vo., 1860; English translation, 2 vols. 8vo., London and Boston, 1861). His "Democracy in America" was translated into English by Henry Reeve, with a preface and notes by John O. Spencer (8vo., 1838), and abridged by the latter under the

title of "American Institutions and their Influence," with notes (16mo., New York, 1856).

TOD, JAMES, an English soldier and author, born in 1782, died in London, Nov. 17, 1835. He went to India in 1800 as a cadet in the East India company's service, and after the close of the Mahratta war was for many years employed in a survey of Rajpootana, of which country he finished in 1815 a magnificent topographical map. The result of his labors appeared in his "Annals of Rajast'han" (2 vols. 4to., London, 1829-'32), containing an elaborate account of the geography, history, and antiquities of the country. Between 1817 and 1828 he held the position of political agent of Mewar and several other Rajpoot states. Subsequent to his return to England in 1823, he was chiefly occupied with literary pursuits, the most important of which, in addition to the work above mentioned, was the preparation of his "Travels in Western India," published posthumously (4to., London, 1839). At the time of his death he held the rank of lieutenant-colonel.

TODD, I. A. S. W. co. of Ky., bordering on Tenn., and drained by Pond river and several large creeks; area, 850 sq. m.; pop. in 1860, 11,575, of whom 4,849 were slaves. The surface is generally hilly and the soil fertile. The productions in 1850 were 803,941 bushels of Indian corn, 208,027 of oats, and 8,789,685 lbs. of tobacco. There were 21 churches, and 409 pupils attending public schools. It is intersected by the Nashville and Kentucky railroad. Capital, Elkton. II. A central co. of Minn., bounded E. by the Mississippi, and N. by Crow Wing and Red Eye rivers; area, 1,464 sq. m.; pop. in 1860, 430. The surface is generally level, interspersed with numerous small lakes, and the soil is productive. Fort Ripley is in this county.

TODD, ELL, M.D., an American physician, born in New Haven, Conn., about 1769, died in Hartford, Nov. 17, 1838. He was graduated at Yale college in 1787, studied medicine in New Haven, and commenced practice in Farmington, where he resided for nearly 80 years. In 1819 he removed to Hartford, and took an active and leading part in founding the insane retreat, one of the earliest hospitals for the insane exclusively, and the fifth hospital in which the insane were treated, in the United States; he presided over this institution till his death. Dr. Todd was the author of several professional monographs and some occasional addresses.

TODD, HENRY JOHN, an English clergyman and author, born in 1763, died at Settrington, Yorkshire, Dec. 24, 1845. He was educated at Oxford, and was successively a minor canon of Canterbury cathedral, vicar of Milton near Canterbury, rector of Allhallows, London, keeper of the manuscripts at Lambeth palace (1803), rector of Settrington (1820), prebendary of York (1830), and archdeacon of Cleveland (1832). His publications comprise editions of the poetical works of Milton and Spenser, with notes and memoirs; "Illustrations of the Lives

and Writings of Geoffrey Chaucer and John Gower" (8vo., 1810); an edition of Johnson's "Dictionary," with corrections and additions (4 vols. 4to., 1814); "A Letter to the Archbishop of Canterbury, concerning the Authorship of Icon Basilikē" (8vo., 1825), which assigns the work to Bishop Gauden; and a life of Archbishop Cranmer (2 vols. 8vo., 1831), growing out of a controversy with Dr. Lingard and others.

TODD, JOHN, D.D., an American clergyman and author, born in Rutland, Vt., Oct. 9, 1800. He was graduated at Yale college in 1822, spent 4 years at the Andover theological seminary, and was ordained to the ministry in the Congregational church at Groton in 1827. In 1833 he was settled over the Edwards church at Northampton, in 1836 was called to the pastorate of the first Congregational church in Philadelphia, and in 1842 became pastor of the first Congregational church in Pittsfield, Mass., which position he still retains. Dr. Todd was one of the founders of the Mount Holyoke female seminary, and has been for 10 years the president of the board of trustees of the young ladies' institute at Pittsfield. In 1845 he received the honorary degree of D.D. from Williams college. Few works by American authors have had so wide a circulation as some of those written by Dr. Todd. He has published "Lectures to Children" (2 vols. 16mo., Northampton), which has been translated into French, German, Greek, Dutch, and Tamil, and several times reprinted in Great Britain; "The Student's Manual" (12mo., Northampton), of which 150,000 copies had been sold in England in 1855, and two translations had been made in France; "The Sabbath School Teacher" (12mo.); "The Lost Sister of Wyoming" (18mo.); "The Bible Companion" (18mo.); "Great Cities, their Moral Influence," &c. (18mo.); "The Young Man" (16mo.); "Simple Sketches" (2 vols. 16mo.); "The Daughter at School" (12mo.); "Summer Gleanings" (12mo.); "Truth made Simple" (18mo.); "Stories on the Shorter Catechism" (2 vols. 16mo.); "The Angel of the Iceberg," &c. (16mo.); "Index Rerum" (4to.); "Question Books on the Life of Adam and Moses" (2 vols. 18mo.); and a great number of sermons, orations, and occasional pamphlets.

TODD, ROBERT BENTLEY, a British physician and physiologist, born in Ireland about the commencement of the present century. He received his education in Ireland, settled in London, and upon the opening of King's college there was appointed professor of physiology and physician of the hospital connected with its medical department, the latter of which offices he still holds. He has considerable reputation as a practitioner, but is best known as the author or editor of a number of important medical works, including the "Cyclopædia of Anatomy and Physiology" (4 vols. 8vo., with supplement), published in conjunction with Dr. Grant; the "Physiological Anatomy and Physiology of Man" (2 vols. 8vo.), in conjunction with Dr. Bowman; "Anatomy of

the Brain, Spinal Cord," &c.; "Lectures on Paralysis and Brain Diseases;" and "Treatise on Gout and Rheumatism." His contributions to medical journals, and papers in the "Medico-Chirurgical Transactions," are numerous.

TODDY TREE. See PALM, vol. xii. p. 708.

TODLEBEN, FRANCIS EDWARD, a Russian general of engineers, born in Mitau, Courland, May 8, 1818. At 14 years of age he entered the engineering school of St. Petersburg, and subsequently was commissioned a lieutenant in the grenadier corps of sappers. For a number of years he was employed by the bureau of engineering in theoretical studies connected with the attack and defence of fortified places, and between 1848 and 1851 he served in the Caucasus against Shamyl. In the latter year he was appointed aide-de-camp to Gen. Von Schilder, a distinguished officer of artillery, and as lieutenant-colonel of the engineers of the guard he participated in the campaign against the Turks on the Danube in 1853-'4. In Aug. 1854, Prince Gortchakoff despatched him, as the best engineer officer under his command, to assist in the defence of Sebastopol, then threatened by the allied French and English forces. He was not intrusted with any important operations until the landing of the allies in the latter part of September; but from that time until the capture of the southern part of the city, in Sept. 1855, he exhibited engineering genius of the first order in the construction of earthworks which baffled every effort of the besiegers. He was severely wounded in the course of the siege, and in the latter part of 1855 was recalled to St. Petersburg, with the rank of aide-de-camp general, for the purpose of strengthening the defensive works at Nikolaiev and Cronstadt. He subsequently received the cross of St. George, and other distinctions. He has not been in active service since the close of the Crimean campaign, nor has he fully recovered of his wound.

TODOS SANTOS (All Saints), a small town in a valley of the same name in the southern portion of the peninsula of Lower California, situated on the Todos Santos river, founded in the beginning of the 18th century by the Jesuits. The principal edifices belong to the mission, and consist of a church with a dome 125 feet high, and a convent and several buildings attached, which are surrounded by a wall 100 feet high and 15 feet thick. The foundations of the wall and of the church are of chiselled stone, but the remaining buildings are of adobes. Jesuit missionaries were sent to this place early in the 18th century from the college in Mexico, with full powers to colonize the peninsula. The mission after the expulsion of the Jesuits came into the hands of the Franciscans, by whom it is still controlled. The valley of Todos Santos is one of the most beautiful and fruitful in America. Cotton, rice, and sugar cane are abundant, coffee and cacao are cultivated, and the region also abounds in tropical fruits.

TODY, a diurnal, fissirostral bird of the roller family, sub-family *todina*, and genus *todus* (Linn.). In this genus, which is peculiar to tropical America, the bill is elongated, very broad and flat, almost like 2 thin plates, the upper mandible usually obtuse at the end, the gape opening as far as the eyes, and the base surrounded by large bristles; nostrils near the base; wings short and rounded, the first 2 quills short and narrow, and the 4th the longest; tail short and rounded; tarsi moderately long and slender, and covered in front by a single scale; outer toe longer than inner, and both united to the middle by membrane; hind toe short, and claws small; margins of the bill finely serrated. They are robust little birds, resembling the kingfishers in form, but having longer tarsi and tail, and a very different bill; they feed chiefly on insects, captured on the trees or on the wing as by the flycatchers; they eat also worms and small reptiles, which they seek upon the ground; their plumage is gaudy, and their flight rapid. The nest is made upon the ground, in a hole dug for the purpose lined with grass and straw, and the eggs are 2 to 4; Prince Neuwied says they make a conical, bag-shaped nest, of wool, with a narrow entrance on the side. The green tody (*T. viridia*, Linn.), very common in some of the West Indian islands, is about the size of a wren, bright grass green above, with the neck and throat red, breast whitish, and abdomen yellowish; it is usually seen singly, and is so stupid or fearless as often to be caught by the hand; it is bold and familiar, and apparently has no fear of man, in captivity seeking its food about an occupied room; it occasionally utters a low hissing note; when at rest it draws the head back, with the bill directed upward and the loose plumage puffed out, giving it a very stupid look; the nest is made in holes in banks dug to a depth of 6 to 12 inches.—These birds are represented in India and its archipelago by the allied family *eurylaimina*, which differ principally in having only the outer toe united to the middle by a web. These are of small size and beautiful colors, living in retired places, in marshy districts, and along the margins of lakes and rivers; they are usually seen in small flocks, feeding on insects, worms, and vegetable substances. The nest is made of small twigs, suspended from branches of trees, usually overhanging the water; the eggs are two.

TOFANA. See AQUA TOFANA.

TOGA, the principal outer garment worn by the Romans. It differed in fashion somewhat at various periods, but had always a general semicircular form. One corner of the garment was placed upon the left shoulder, the remainder passed behind the body, over the right shoulder, and across the breast, the end being thrown back over the left shoulder. Behind the wearer, the garment reached very nearly to the feet. Togas were commonly made of wool. The toga worn by men, *toga virilis*, was entirely white; the *toga praetexta*, worn by

various officers in the state, and by children of both sexes, had a broad purple border. The toga is supposed to have been received from the Etruscans. Originally it was worn by both sexes, but upon the introduction of the *stola* that garment was assigned to the Roman women, and the toga became the peculiar distinction of Roman men. Its use was forbidden to exiles and foreigners. In war it was laid aside, and it was chiefly worn in Rome; hence *togatus* is opposed to *miles* and to *rusticus*.

TOISE, an old French measure of length, which contains 6 French feet, or 1.949040 metres. It is equivalent to 6.3945925 English feet.

TOKAT, or TOCAT, a town of Asiatic Turkey, in the pashalic of Sivas, situated on the Yeshil-Irmak (the ancient Iris), in lat. 40° 7' N., long. 36° 30' E.; pop. 100,000. It has high limestone hills on 3 sides, and is commanded by 2 peaks which are almost perpendicular and consist of crystalline marble. The town has a mean appearance, the houses being built of mud or unburned bricks. The manufactures consist chiefly of copper articles and hardware, woollen, linen, silk, cotton goods, and carpets; and there are dyeing and calico printing establishments. A considerable trade is carried on in supplying the surrounding country with manufactured goods, as well as by caravans with all parts of Asia Minor; but the commercial importance of Tokat is not so great as in former times. The inhabitants are chiefly Turks, but there are a large number of Armenians and a few Greeks.

TOKAY, or TOKAJ, a town of Hungary, in the county of Zemplén, situated at the junction of the rivers Bodrog and Theiss, in lat. 48° 7' N., 114 m. E. N. E. from Pesth, and 25 m. S. S. W. from Sátoralja-Ujhely; pop. 5,712. The Theiss is crossed by a large wooden bridge, and the town contains several churches. Some trade is carried on, and several important fairs are held annually. Tokay is celebrated for the superior quality of the wine produced in its vicinity, especially in the Hegyalja, a chain of hills to the N. W. of the town, about 20 m. long, covered with vineyards. The grapes are collected with great care, being plucked one by one when they are ripe. The wine produced is of three descriptions: the essence, or that which runs from the grapes when put into a cask without artificial pressure; the second sort is obtained by applying a slight pressure; and the third by the same amount of pressure that is required in the manufacture of ordinary kinds of wine.

TÖKÖLYI, or TÖKÖLI, IMRE. See HUNGARY, vol. ix. p. 359.

TOLAND, JOHN, a British author, born near Londonderry, in Ireland, Nov. 30, 1669 or 1670, died at Putney, near London, March 11, 1722. His parents were Roman Catholics, but he says that he was as zealous against that faith before he was 16 years old as he continued to be ever after. He studied 3 years at

the university of Glasgow, received the degree of M.A. at the university of Edinburgh in 1690, was sent by influential English dissenters for two years to the university of Leyden to prepare for the ministry, gained the friendship of Le Clerc and Leibnitz, and then went to Oxford, where he collected materials on various subjects in the Bodleian library, and made himself conspicuous as a free thinker. He published in London in 1696 a work entitled "Christianity not Mysterious," designed to show that no Christian doctrine is contrary to reason, or above it, or can properly be called a mystery. Among the answers which it called forth was the treatise on "Reason and Faith" (1697), by the Rev. John Norris of Sarum. He became acquainted with Locke, and in 1697 went to Dublin, where he was esteemed as a man of parts and learning, but alarmed the clergy and excited the clamor of parties, "not so much by his difference in opinion, as by his unreasonable way of discoursing, propagating, and maintaining it." His book was ordered by the parliament at Dublin to be burned by the common hangman. He returned to London, and, after publishing "An Apology for Mr. Toland," wrote numerous pamphlets and treatises on questions of politics, religion, and literature. Among them were a pamphlet entitled "The Militia Reformed, or an Easy Scheme of Furnishing England with a constant Land Force" (1698); a "Life of Milton" (1698), and a defence of it against a criticism of Dr. Blackall (1699); editions of Lord Holles's "Memoirs" and of Harrington's "Works;" a poem on eloquence entitled "Clito;" and "Anglia Libera" (1701), a treatise on the succession of the crown of England. He visited the courts of Hanover and Berlin, apparently as a political agent, and held a theological discussion with Beausobre. Having returned to England, he professed himself in 1702 "a true Christian" and "a good churchman," and in 1705 declared himself a pantheist, and wrote political pamphlets for Harley, by whom he was sent again in 1707 to Germany and Holland. He remained abroad about 3 years as a secret political spy, ingratiated himself with Prince Eugene in 1710, and was afterward supported for a time by the earl of Oxford (Harley), but at length quarrelled with his patron and wrote pamphlets against him. Among his numerous later publications are treatises with long and fantastic titles, as "Nazarenus, or Jewish Gentile, or Mahometan Christianity, containing the History of the Ancient Gospel of Barnabas, and the Modern Gospel of the Mahometans, attributed to the same Apostle, this last Gospel being now first made known among Christians," &c., which involved him in protracted controversies. During the last 4 years of his life he lodged at Putney, having found a patron in Lord Molesworth. "Never," says Disraeli in his "Calamities of Authors," "has author died more in character than Toland; he may be said to have died with a busy pen in his hand. Having suffered from

an unskilful physician, he avenged himself in his own way; for there was found on his table an 'Essay on Physic without Physicians.' The dying patriot-trader was also writing a preface for a political pamphlet on the danger of mercenary parliaments; and the philosopher was composing his own epitaph, one more proof of the ruling passion predominating in death." His posthumous works were published in 2 vols. in 1726 (reprinted, 1747), with a biography by Des Maizeaux. His writings have never been collected, though many of them contain curious and interesting details concerning the history of the times.

TOLDY, FERENCZ, M.D., a Hungarian literary historian and critic, born in Buda, Aug. 10, 1805. His original name was Schedel, which he in after life exchanged for his *nom de plume*. He studied medicine at the university of Pesth, and philosophy at that of Berlin, where he also lectured on Hungarian literature, in 1830 made a tour through Belgium, England, France, and upper Italy, and on his return to his country became a member and chief secretary of the Hungarian academy. Having for a number of years been active as a medical writer and professor of hygiene at the university of Pesth, he in 1844 resigned that position, and exclusively devoted himself to the study of the literary history of his nation, which he had long and successfully cultivated. His principal works are: *Handbuch der ungarischen Poesie* (Pesth and Vienna, 1828); *Magyar chrestomathia* (2 vols., Pesth, 1853); and *A magyar nemzeti irodalom története* ("History of the National Hungarian Literature," 8 vols., Pesth, 1851-'5), of which he has also published a German translation. He has, however, been chiefly occupied as editor of the *Athenaeum* (in conjunction with Bajza and Vörösmarty, 1837-'44), of the *Uj magyar museum* (since 1850), of the "Annals" of the Hungarian Academy and of the "Kisfaludy Society" (as secretary to both), and of the works of Dayka, Czuczor, Kazinczy, the two Kisfaludy, Csokonai, Vörösmarty, and other national authors.

TOLEDO, a city of Ohio, near the western extremity of Lake Erie, 100 m. W. from Cleveland and 60 m. S. W. from Detroit, situated on the estuary of the Maumee river, in lat. 41° 30' N., long. 83° 32' W.; pop. in 1840, 1,282; in 1850, 3,829; in 1860, 13,768. It is one of the most important commercial towns on the lakes, possessing a fine harbor and unsurpassed facilities for internal trade. It is well laid out, chiefly on elevated ground, having wide streets, many of which are graded, giving an easy ascent from the harbor to the table land on which most of the houses are built. It has several large and handsome public buildings, and a considerable number of private residences in good style and with tastefully adorned grounds. It is becoming eminently healthful, the deaths for the 3 past years averaging but 2.15 per cent. of its whole population. There are 2 daily and 2 tri-weekly newspa-

pers, and one (German) weekly. There are 13 churches, an Ursuline convent, an orphan asylum, a Bethel church for sailors, 2 banks, 2 private banking houses, a savings bank, large warehouses, railroad machine shops, foundries, 3 flouring mills, and various other manufacturing establishments. Its high school and district schools are liberally sustained, and there is an excellent library belonging to the young men's association. Toledo is accessible to 6,000 m. of lake shore. By canals it reaches S. W. 460 m. to Evansville, and S. 247 m. to Cincinnati. By 6 completed lines of railroad it is connected with Cleveland, Cincinnati, Lafayette, St. Louis, Quincy, Peoria, Chicago, and Detroit. All these railroads concentrate at an immense union depot, which for convenience is not surpassed in the country. The total commerce for the year ending Dec. 31, 1860, was as follows: value of exports, \$52,943,627.65; of imports, \$46,727,754.69; entrances, 2,133 vessels of 843,114 tons; clearances, 1,986 vessels of 884,503 tons. The enrolled and licensed tonnage of the district was 4,491. Its receipts of breadstuffs, reckoning flour in bushels, in 1861, were 18,706,510 bushels. In provisions and other materials of western commerce, its business was proportionately large.

TOLEDO, a province of Spain, New Castile, bounded N. by Avila and Madrid, E. by Cuenca, S. by Ciudad Real, W. by Caceres; area, 5,620 sq. m.; pop. in 1857, 828,755. The surface is generally mountainous, and there are elevated plains toward the centre. The Tagus flows W. through the middle of the province, and receives many tributaries, the most important of which are the Guadarrama, Alberche, Tietar, Aljoder, and Torcon. Beside these, the Jiguela and its affluents flow toward the Guadiana. Gold, silver, lead, iron, copper, quicksilver, tin, cinnabar, alum, bismuth, coal, and ochre are all found. The soil is generally poor, but in the centre and toward the S. the quality improves. Grain of different kinds, flax, fruit, and vegetables are produced, together with wine, oil, and silk.—*Toletum* (anc. *Toletum*), the capital, is situated on the N. bank of the Tagus, 2,400 feet above the level of the sea, and 42 m. S. S. W. from Madrid; pop. about 14,000. It stands on a rocky height, upon three sides of which the river flows in a deep and narrow channel, crossed by two stone bridges about 100 feet in height, one of which was built by the Moors and consists of a single arch. The surrounding country is undulating and generally barren, and the heat in summer is very great. Toledo is encircled by two walls, and entered by 9 gates, some of which are highly ornamented. The streets are steep, crooked, and narrow, but are tolerably clean. The houses are generally built in the Moorish style, from 2 to 4 stories high and roomy, with the apartments arranged round a court. The appearance of the city is remarkably picturesque. The cathedral, founded in 1258, stands in the centre of the town, and is one of the

finest in Spain. It is of the purest Gothic style, 404 feet long and 204 feet wide, with a spire 324 feet high. The palace of the archbishop (who is the primate of Spain) adjoins the cathedral, and contains a library very rich in ancient manuscripts. The Alcazar, or royal palace, is in a very dilapidated state. The university was suppressed in 1845. The principal manufactures are woollen and silk goods, oil, leather, and the sword blades for which the town is so famous. (See SWORD.)—According to tradition, Toledo was founded by Jewish colonists in the 6th century B. C., and called Toledom, "mother of people." It was taken by the Romans in 192 B. C., and some portions of the walls and an amphitheatre erected by them still remain. It was taken by the Goths in A. D. 467, and made the capital of Spain in 567. The Moors captured it in 711, and under them it made great advances. Alfonso VI. of Castile and Leon wrested it from the Moors after a terrible siege in 1085, when it was again made the capital of the Christian kings, and at one time had a population of 200,000. It afterward suffered many sieges, which, together with the removal of the court to Madrid, have been the chief causes of its decline. It was occupied by the French from 1808 to 1813.

TOLLAND, a N. E. co. of Connecticut, drained by the Willimantic and Hop rivers; area, 440 sq. m.; pop. in 1860, 21,187. In the W. part the surface is nearly level and the soil fertile, but the E. part is very hilly and the soil inferior. The productions in 1850 were 127,873 bushels of Indian corn, 81,429 of oats, 204,353 of potatoes, 88,992 tons of hay, 381,165 lbs. of butter, and 264,698 of cheese. There were 14 cotton and 19 woollen factories, 88 hat and cap manufactories, 5 founderies, 1 glass and 3 hardware factories, 8 machine shops, 7 grist mills, 4 saw and planing mills, 9 sewing silk and 2 thread manufactories, 4 paper mills, 9 tanneries, 41 churches, 2 newspaper offices, and 4,346 pupils attending public schools. It is intersected by the Hartford, Providence, and Fishkill, and the New London northern railroads. Capital, Tolland.

TOLLENDAL. See LALLY-TOLLENDAL.

TOLLENS, HENDRIK CORNELISZON, a Dutch poet, born in Rotterdam, Sept. 24, 1780, died in 1856. His first poems were songs which he wrote for a patriotic society after the French entry into Holland. He published volumes of minor poems in 1800 and 1802, and in 1805 the drama of "Lucretia," which was prohibited by the government. Another tragedy, *De Hoek-schen en Kabeljauwvchen* ("Hooks and Codfish"), was founded on the hostilities of two Dutch factions which were so named in the 14th and 15th centuries. His popularity began with the appearance of a collection of his poems in 1808, one of which, "To a Fallen Maiden," was specially admired; and he became the favorite national poet, and the head of the school of Rotterdam. For the third edition of his poems (1817), many of which are

on national and domestic subjects, there were more than 10,000 subscribers. He afterward published *Nieuws Gedichten* (1821 and 1829) and *Volksliederen* (1833), and before his death prepared a new and complete edition of his works (5 vols., 1853-'5). On his 70th birthday the king of Holland sent him his congratulations through the minister of justice, and created him commander of the order of the lion of Holland; a gold medal was struck in his honor; and a fund was formed for the commemoration of his name by a charitable institution.

TOLTECOS, or TOLTECOS (Aztec, *Tultuacaeas*), the inhabitants of Anahuac (Mexico) prior to the arrival of the Aztecs, and the founders of the ancient Mexican civilization. Their capital was Tula, N. of the valley of Mexico, where on the arrival of the Spaniards remains of extensive buildings were still to be seen. Many other ancient ruins throughout Mexico are attributed to them, and the name Toltec has there become synonymous with architect. By the general agreement of the traditionary legends of the nations that succeeded them, says Prescott, "the Toltecs were well instructed in agriculture and many of the most useful mechanic arts; were nice workers of metals; invented the complex arrangement of time adopted by the Aztecs; and, in short, were the true fountains of the civilization which distinguished this part of the continent in later times." According to the tradition which has generally been followed, they migrated from the north some time in the 7th century A. D., found Anahuac occupied by a savage race, whom they subdued and instructed in their own civilized arts, and established their dominion over the whole country; but 4 centuries after their immigration, reduced by famine, pestilence, and unsuccessful wars, the great body of them departed southward, and founded in Chiapas and Guatemala the cities whose ruins still excite the wonder and admiration of travellers. Later investigations, however, have led to the supposition that their original seat was in the latter region, and that of the Aztecs still further south. (See AZTEC.) A few of the Toltecs still remained in Anahuac on the arrival of the Chichimecs, Aztecs, and other tribes, who, while adopting their civilization, engrafted upon it savage rites and practices to which the Toltecs were strangers.

TOLU, BALSAM OF. See BALSAMS.

TOMATO (*lycopersicon esculentum*, Dunal), a plant of the nightshade family, natural order *solanacea*, the fruit of which, possessing an agreeable acid flavor, is employed in various ways for the table. It is supposed to have originated in South America, and to have been early cultivated in Mexico and Peru. Several varieties were known in England in Gerard's time (1597), and Parkinson in 1656 speaks of them as garden curiosities under the names of love apples, amorous apples, and golden apples, more for their beauty than for any supposed use. On the continent Dodoens,

a Dutch herbalist, in 1583 mentions them as vegetables to be eaten with pepper, salt, and oil. Rumphius in his *Herbarium Amboinense* (1755) speaks of two kinds called *tomatla*, used in cooking among the Malays; and the word *tomatl* is applied to several species of *solanum* among the Mexicans. Formerly they were called *pomi d'oro* by the Italians, and now are known as *pomi d'amore* and extensively cultivated around Naples and Rome. The several varieties are known by the form and color of the fruit, and each was described as a distinct species by Dunal, who examined them structurally and noticed their distinctive characteristics in his "Natural History, &c., of the *Solanum*" (Montpellier, 1813), but which nevertheless can be referred to a common type, viz., the large red tomato, with deeply divided, rough, hairy leaves, and clusters of yellow flowers, succeeded by large, lobed fruit of an orange-red or scarlet color when ripe. The mode of growth in stem, foliage, and flower is indeed much the same in every variety, the plant being annual, with long, prostrate, branching stems, of a grayish hue and viscid-pubescent; leaves of the same character, unequally pinnate, the leaflets deeply cut, acuminate, glaucous beneath; flowers in naked lateral clusters, supported on a common, slender, fork-branched peduncle; calyx with 5 or 6 segments; corolla rotate, 5 or 6 cleft, yellow, pubescent; stamens 5, with conical anthers, which are connate at their extremities and dehiscence lengthwise; fruit a berry of 2 or 3 cells, with flat, hairy seed enveloped in a juicy pulp. The small red tomato has a globular fruit, somewhat flattened near the stem and at its apex. The pear-shaped tomato is ovate and tapering toward the stem; it is tender and ripens more tardily. The cherry tomato has a small, round, red fruit, possessing a sprightly acid flavor, but on account of its size used chiefly for pickling. The large yellow tomato is nothing but a variety of the large red, and the small red a variety of the cherry tomato, as likewise the fig tomato, which when dried is prepared as a sweetmeat. Some much improved varieties of the tomato are at present in great repute, such as the perfected tomato, with large juicy fruit of either a scarlet color or else a crimson tinted with violet. The upright tomato is recommended because its stems are erect and its habits are better suited to small gardens. A species (*L. Humboldtii*) was introduced to notice, being brought from Peru, about 40 years since, which is said to be a perennial.—The tomato is readily raised from seeds or from cuttings, but the former is the usual mode, sowing in hot-beds or sheltered frames in March, and transplanting into the open ground when the weather permits, cold and frost being destructive to the young plants. A light, rich mould, upon a porous subsoil, is preferable, and a warm sunny exposure will be found advantageous. The plants as they grow may be supported by a low framework, and

even training upon trellises or against sunny walls can be recommended where early fruits are wanted. The process consists in tying or nailing the branches as they grow and nipping off the lateral shoots, but carefully preserving those leaves which are near the flowers. The fruit of the earliest and best, well ripened, should be selected for seed.

TOMBIGBEE, TOMBIGBY, or TOMBECKEE, a river of Mississippi and Alabama, which rises in Tishemingo co. in the N. E. extremity of the former state. It first flows S. to Columbus, thence S. E. to Demopolis, Ala., where it receives the Black Warrior on the left, and thence generally S., with many and sudden windings, to its junction with the Alabama, about 45 m. from Mobile, where the united stream takes the name of Mobile river, and falls into Mobile bay about 80 m. from the gulf of Mexico. Its length is estimated at 450 m., and it is navigable for large steamboats to Columbus, 366 m. from the mouth of Mobile river, and for smaller boats to Aberdeen, about 50 m. further up.

TOMLINE, GEORGE, an English prelate, eldest son of George Pretymann, born in Bury St. Edmunds, Oct. 9, 1750, died in Sept. 1837. He was educated at Cambridge, and in 1773 became tutor to William Pitt, and in 1782 his private secretary when the latter was made chancellor of the exchequer. When Pitt became first lord of the treasury, Pretymann was made his secretary, and remained with him till 1787. After having received various preferments, he was made in 1787 bishop of Lincoln and dean of St. Paul's, and in 1820 was transferred to the see of Winchester. In 1803 Bishop Pretymann assumed the name of Tomline in consequence of having received by will an estate from Marmaduke Tomline, who was no way related to him. He published "The Elements of Christian Theology" (2 vols.), "A Refutation of Calvinism," and "Memoirs of William Pitt" (3 vols. 8vo.).

TOMMASEO, NICOLÒ, an Italian author and revolutionist, born in Sebenico, Dalmatia, in 1803. He was educated in Italy, and spent several years in Florence, where he was one of the most active writers for the *Antologia*; but, suspected by the Austrian government, he went in 1833 to France. After the amnesty of 1838 he engaged in literary pursuits in Venice. At the end of 1847, he along with Manin signed a petition to the emperor for a milder exercise of the censorship; and in Jan. 1848, the popularity of these two leaders of the national party caused their arrest and imprisonment. The uprising of the people effected their release in March, and Tommaseo became a member of the provisional government. From this he withdrew in June, but in August returned as minister of public instruction; and he made two unsuccessful journeys to Paris to secure the aid of the French republic. After his return in Jan. 1849, he lost his influence in Venice almost entirely, in consequence of his moderate views, but on the

capitulation of the city he was one of the 40 patriots who were exiled. Since that time he has resided chiefly in Corfu and Turin. Tommaseo is one of the most eminent of the writers of young Italy who have sought to unite the religious principles of Catholicism with liberty and liberal opinions. Of his numerous writings the most important are: *Nuovo dizionario dei sinonimi della lingua Italiana* (Florence, 1832; new ed., 1839-'40); a commentary upon Dante (Venice, 1837); a collection of papers of the Venetian embassy bearing upon the history of France during the 16th century (2 vols., Paris, 1838); *Nuovi scritti* (4 vols., Venice, 1839-'40); *Studi critici* (2 vols., Venice, 1843); and *Lettere di Pasquale de' Paoli* (Florence, 1846), with a valuable history of Paoli's life, and of the war for Corsican independence. He has also made a collection of popular songs, Tuscan, Corsican, Dalmatian, and Greek, under the title of *Poesie popolari Italiane* (4 vols., Venice, 1839-'42), with historic notices.

TOMPKINS, a central co. of New York, drained by several tributaries of Cayuga lake, the head of which lies in the N. part of the county; area, 506 sq. m.; pop. in 1860, 81,411. The surface is hilly, the valley of the lake being 700 feet below the ridges on either side, and the soil is generally best adapted to grazing. The productions in 1855 were 117,048 bushels of wheat, 372,202 of Indian corn, 82,816 of barley and rye, 812,988 of oats, 74,803 of buckwheat, 111,106 of potatoes, 417,757 of apples, 31,843 tons of hay, 79,932 lbs. of flax, 27,090 of tobacco, 1,645,947 of butter, and 160,884 of wool. There were 28 grist mills, 97 saw mills, 14 tanneries, 9 furnaces, 3 woollen factories, 2 paper mills, 3 oil cloth factories, 66 churches, and 4 newspapers; in 1859 there were 11,918 pupils attending public schools. Cayuga lake supplies water communication with the Erie canal. The Cayuga and Susquehanna railroad passes through the county. Capital, Ithaca.

TOMPKINS, DANIEL D., an American statesman, born at Scarsdale, Westchester co., N. Y., June 21, 1774, died on Staten island, June 11, 1825. He was graduated at Columbia college in 1795, studied law, was admitted to the bar in New York in 1797, and soon attained a high position both in and out of his profession. In 1801 he was elected a member of the legislature, and also of the convention for revising the state constitution. In 1804 he became a member of congress from the city of New York, and the same year was appointed one of the associate justices of the supreme court of the state. In 1807 he was elected governor of New York, and continued to fill that office by reelection till 1817, when he resigned in consequence of his election as vice-president of the United States; in 1820 he was reelected to the latter office, which he held till March 4, 1825. During the war of 1812, by his exertions in calling out troops and sending them into the field, he contributed largely to the national success. In 1812 he prorogued

the state legislature for 10 months, to prevent the establishment of the bank of America in the city of New York, which was intended to take the place of the old United States bank. This measure gained him great popularity at the time, but did not in the end defeat the charter of the bank, which was passed in 1818. In a special message to the legislature, dated Jan. 28, 1817, he recommended the total abolition of slavery in the state of New York; and an act for that purpose was accordingly passed, to take effect July 4, 1827.

TOMSK, a government of Western Siberia, bounded by Tobolsk, Yeniseisk, the Chinese empire, and the Kirgheez territory, from which it is separated by the Irtysh; area, 139,472 sq. m.; pop. in 1856, 687,677. The Altai mountains extend along the S. part, and the surface descends toward the N. The river Obi rises in the S. of the government, flows N. W., and receives numerous tributaries, the chief of which are the Bia, Tchumish, Tom, Tchulim, and Ket. There are several lakes of considerable size, particularly in the west. Gold, silver, copper, lead, and iron are all found in the mountains of the S., and extensively worked. A great deal of the N. part of the province is barren, and only supports the slender flocks and herds of some nomadic tribes; but toward the S. the pastures become luxuriant, and abundant crops are raised, but cattle constitute the principal wealth of the people. The population is composed of Russians, Cossacks, Tartars, and Ostiaks. The principal towns, beside the capital, are Biliak and Kolyvan on the Obi, and Ust-Kamenogorsk and Semipalatinsk on the Irtysh.—TOMSK, the capital, is situated on the right bank of the river Tom, in lat. 56° 29' N., long. 85° 10' E., 610 m. E. from Tobolsk; pop. about 10,000. It consists of an elevated part which stands upon hilly ground, and a lower town or suburb; the former is principally inhabited by Russians, and the latter by Tartars and people from Bokhara. There are manufactures of coarse cloth, leather, and soap; and a considerable traffic is carried on with the Calmucks and Ostiaks in cattle, furs, fish, &c., for which European, Bokharian, and Chinese goods are exchanged. The great road leading to the frontier of China passes through the lower town.

TON, or TUN, a denomination of weight, equal to 20 cwt. or 2,240 lbs., and also (usually with the second orthography) a liquid measure of 252 gallons; also applied to dry measures and solid measures of various capacities. The tons used by different nations in shipping are often entirely different from their ordinary measures of the same name. In common use, the ton weight is often rated at 2,000 lbs., when it is termed the "short ton;" but by act of congress, when not specified to the contrary, the ton is to be understood as 2,240 lbs. The different values of the ton weight involve great confusion in commercial transactions. Mr. Alexander, in his "Universal Dictionary of

"Weights and Measures" (Baltimore, 1850), gives 50 different kinds of tons, and there are some used for coal, and perhaps others also, which he does not name; thus in Maryland the ordinary ton is 2,000 lbs., the usual coal ton 2,240 lbs., and the miner's ton, according to which he is paid, is 2,470 lbs., the allowance being for waste. The shipping ton of France was by the old standard 2,158.48 lbs., and the metrical ton is 2,204.74 lbs.; of Spain, 2,032 lbs.; of Portugal, 1,755.8 lbs. The measurement ton for shipping is in the United States 40 cubic feet; in China and India, 50; in Portugal, 73.8; in France, 50.842; and in Hamburg, 83.219. As a measure of dry capacity, there are in Germany, Holland, and Sweden not fewer than 6 different tons, varying from 3.04 to 5.18 bushels; while the shipping tons of Portugal, France, and Italy range from 41.48 to 48.98 bushels. The liquid tun measure is quite as varied in Europe, and as applied to different articles, as wine, beer, &c. In England the tun for wine is 252 gallons, and for beer 263.7 gallons. Of the vessels called tuns, the most famous is that known as the great tun of Heidelberg, the capacity of which is 288,200 bottles of wine; but it has remained empty since 1769.

TONE, THEOBALD WOLFE, an Irish revolutionist, born in Dublin, June 20, 1763, died in prison there, Nov. 19, 1798. He was educated at Trinity college, Dublin, and in 1785, before he had completed his course, made a runaway marriage, which turned out happily. Early in 1787 he went to London and entered the Middle Temple, and in 1789 was called to the bar. He disliked the profession extremely, and paid too little attention to it to be successful. In defence of the whig club he published at this time his first pamphlet, "A Review of the Last Session of Parliament." Not long afterward, on the appearance of a rupture with Spain, he wrote a pamphlet to prove that Ireland as an independent nation was not bound by a declaration of war. Embracing the liberal ideas to which the French revolution had given life and power, he actively devoted himself to the task of effecting a union against the government between the Catholics of Ireland and the dissenters, and in 1791 addressed to the latter a pamphlet entitled "An Argument on behalf of the Catholics of Ireland," which was very successful. The same year he assisted in founding the first club of "United Irishmen" at Belfast, and in forming them in other parts of Ireland. But as these clubs soon became perverted from their original aims of Catholic emancipation and parliamentary reform to the more extreme measures for revolutionizing the country, he lost in them almost all his influence. In 1792 he succeeded Richard Burke, the son of Edmund Burke, as the secretary and agent of the Catholic committee, and subsequently became implicated in the proceedings of Jackson, sent from France to sound the sentiments of the Irish. By a kind of compromise with the government, he was allowed to retire from the

country, and in 1795 came to the United States, where he lived in succession at Philadelphia, West Chester, and Downingtown, Penn., and at Princeton, N. J. Urgent letters from Ireland, stating that that country was ripe for a revolt, induced him to sail for France in Jan. 1796, to gain the aid of the directory; and owing in large measure to his exertions, that government determined to fit out a powerful expedition, the command of which was given to Hoche. In July Tone received his commission as *chef de brigade*, and was also made an adjutant-general to Hoche, whom he accompanied in Dec. 1796, in the armament destined for Bantry bay. The fleet was scattered by storms, and Tone was unable to persuade the French government to undertake another expedition on a large scale. In 1797 he was attached to the Bavarian army; and, still persevering in the project of raising an insurrection in his native land, in Sept. 1798, he accompanied a petty squadron destined for Ireland, which was intercepted and defeated by an English squadron under Sir John Borlase Warren. After fighting desperately, Tone was taken prisoner. He was not at first recognized, but at Letterkenny was placed in irons, taken to Dublin, tried by court martial, and sentenced to be hanged on Nov. 12. On the 11th he cut his throat with a penknife, and died in consequence a few days afterward. His autobiography, with a diary kept during his residence in France, was published by his son, William Theobald Wolfe Tone (Washington, 1826), who was an officer in the army of Napoleon, and after his fall in that of the United States.

TONGATABOO. See FRIENDLY ISLANDS.

TONGUE, the symmetrical organ, situated on the median line, at the commencement of the alimentary canal, ministering to the senses of touch and taste, variously used in the collection and preparation of the food for deglutition, and the principal instrument in the articulation of sounds. Taking the tongue of man as an example, the organ is attached at its base to the movable hyoid arch of bones, and suspended and kept in place by muscles from the skull, sternum, and scapula; it is essentially composed of muscular fibres, which move freely its various portions; it is covered by very sensitive mucous membrane, containing numerous mucous glands and follicles; fibrous, areolar, and fatty tissues enter into its structure, which is freely supplied with blood vessels and nerves. The size varies, bearing no relation to the height of the individual, but proportioned to the capacity of the alveolar arch; it is, therefore, smaller in women than in men. It follows about the direction of the lower jaw in its anterior half, and behind that curves downward and backward to the hyoid bone; it is free except at the posterior extremity and the posterior $\frac{1}{3}$ of the lower surface; from the base to the epiglottis extends a fold serving to limit the movements of the latter organ, and from the sides of the base to the soft palate 2 folds on each side, the

pillars of the fauces, between which are situated the tonsils; under the anterior free extremity is the frenum which connects it with the lower jaw, a fibrous and mucous lamina or ligament, sometimes so short congenitally as to prevent the free movements of the tongue and to require an operation for its division. There is a more or less distinct longitudinal furrow on the median line, from which extend outward and forward numerous other lines whose angle of union points backward; the posterior 3d is smooth and without compound papillæ, exhibiting a few simple ones and the nodular eminences of the numerous muciparous glands; in front of this is a V-shaped ridge, the angle directed backward, formed by 2 converging lines of button-like eminences, the circumvallate papillæ; in front of these, and occupying the anterior $\frac{1}{3}$ of the organ, are the fungiform and conical or villiform papillæ, the former spheroidal, red, and scattered, the latter very numerous. The osseous support of the tongue is the U-shaped or hyoid bone, consisting of a base or median body, 2 greater and 2 lesser cornua, and placed in the neck between the lower jaw and the thyroid cartilage; it is the homologue of a very complex apparatus in the lower vertebrates. The muscles constitute the chief bulk of the tongue, and perform its functions in prehension, mastication, deglutition, and speech; they are arranged in a complicated manner, so as to mutually support each other, rendering the movements of the organ exceedingly varied and extensive; they are attached to the submucous fibrous tissue, which is firm and thick on the superior surface. The mucous membrane is invested with a delicate scaly epithelium, the superficial layer of which readily and constantly falls off. The papillæ are much like those of the skin, most being compound organs, in their nervous and vascular supply; the circumvallate are 6 to 10 in number, and sometimes $\frac{1}{3}$ of an inch in diameter; the fungiform are $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in diameter, and vary greatly in number, perhaps accounting for the well known diversity in the acuteness of the sense of taste in different individuals; the filiform are the most numerous, closely set like the pile of velvet, covering the anterior $\frac{2}{3}$ of the tongue, and the seat of what is called the fur; their epithelium frequently breaks up into hair-like processes, having their imbrications directed backward, which mark a physiological distinction between the sentient circumvallate and fungiform papillæ and the protective and motor filiform and conical ones. The conical papillæ are generally regarded as tactile, the fungiform and circumvallate as gustatory (acutely tactile), and the filiform as the homologues of the recurved spines of the tongue of the cats, and as principally concerned in regulating the movements of the food in order to bring it within the reach of the muscles of deglutition. The principal arteries of the tongue are the lingual branches of the external carotid; the sensory nerves are the lingual branch of the 5th pair of trifacial

and the glossopharyngeal, distributed respectively to the anterior and posterior portions, and the motor nerve is the hypoglossal; for their functions see TASTE. The tongue in fishes is rudimentary, and not endowed with any great sensibility or motile power; in reptiles it varies greatly in length, size, and movability, being in some immovable or short and thick, in some remarkable for slenderness and length (as in serpents), and in others for protractility (as in the chameleon and frog); in them it is usually an organ of prehension and not of sensation. The tongue in birds is also prehensile and not gustatory, and generally provided at the base with numerous spines directed backward to prevent the return of food; though itself incapable of elongation, it may be remarkably protruded by the action of the muscles attached to the very long and movable hyoid bones. In some mammals, as the giraffe and ant-eater, it is capable of great elongation, and is an important organ of prehension; the recurved spines of the cats have been referred to, and constitute efficient instruments for cleaning flesh from bones and for combing their fur. In man the tongue is not, properly speaking, prehensile, but is engaged in the acts of suction and drinking, as every one knows; it keeps the food during mastication within the range of the teeth, collects it from all parts of the mouth preparatory to swallowing, and is also concerned in the commencement of deglutition; and it is the principal organ of speech. It is liable to inflammation, enlargement, atrophy, ulcerations, tumors, and malignant diseases. The fur in disease depends on a sodden and opaque condition of the epithelium of the filiform and conical papillæ, arising from an alteration of the mucus and saliva of the mouth, the bright red color of the fungiform presenting a striking contrast; the amount, color, and arrangement of the fur are symptomatic of various morbid changes in the system of interest to the physician, though there is great variety within the limits of health. The papillary surface is healed and repaired with great readiness and perfection.

TONIC (Gr. *tonos*, to strengthen), a medicine used for increasing permanently the strength of the organic actions of the different systems of the animal economy, giving a durable exaltation to the energies of all parts of the frame, without necessarily producing any apparent increase of the healthy actions. Extracts of bitter substances (see BITTER PRINCIPLES) are much used for this purpose, as also tincture of iron, arsenic, and the like.

TONNA, CHARLOTTE ELIZABETH, better known by her *nom de plume* of "Charlotte Elizabeth," an English authoress, born in Norwich in 1792, died in London, July 12, 1846. She was the only daughter of the Rev. Michael Brown, rector of St. Giles's, Norwich, and a canon of the cathedral. She injured her health in childhood by intense study. She was first married to Capt. George Phelan of the British

army, with whom she resided in Nova Scotia for 2 years, and subsequently for 5 more in Ireland. Her husband becoming insolvent, and finally insane, she was compelled to resort to literature for a livelihood, and wrote numerous religious narratives and tales, which were very popular, and still remain so. In 1841 she was married a second time to Mr. L. H. J. Tonna of the united service institution, whose sympathy with her literary pursuits stimulated her to new exertions. Of her works, nearly 50 in number, the titles of those best known are: "Judah's Lion," "Judæa Capta," "Helen Fleetwood," "Personal Recollections," "Chapters on Flowers," "Glimpses of the Past," "Principalities and Powers," "The Siege of Derry," "Count Raymond of Toulouse," "The Deserters," and "Wrongs of Women."

TONQUIN. See ANAM.

TONQUIN, GULF OF, an arm of the China sea, having the province of Tonquin on the W, the Chinese province of Quang-tung on the N. and E., and the island of Hainan on the S. E.; length, 800 m.; average width, 150 m. The Sangkoi or Tonquin river and several smaller streams flow into it. It has numerous islands. The typhoons are very violent in the gulf.

TONSILS, or AMYGDALÆ, a collection of mucous follicles situated in the throat on each side in the interval between the pillars of the fauces. They are almond-shaped, with the larger end directed upward; hence their Latin name given above, and the popular one of "almonds of the throat." They vary in size in different individuals, being generally the largest in scrofulous constitutions; their excretory ducts terminate in small sacs imbedded in their substance, and open on the mucous membrane, their secretion serving to lubricate the parts concerned in deglutition. They are well supplied with blood from the facial, inferior pharyngeal, and internal maxillary arteries, and there is a considerable network of veins around them; they receive numerous nervous filaments from the glosso-pharyngeal, par vagum, and trifacial. The external surface is adherent to the superior constrictor of the pharynx, while the internal is free and prominent; the carotid artery is behind and to the outside, which must be borne in mind in puncturing the abscesses to which they are very subject. These organs are liable to acute and chronic inflammations, with the exudation of whitish and tenacious false membranes, and great enlargement, often impeding respiration and deglutition. Their common acute inflammation is popularly called quinsy and inflammatory sore throat; it generally arises from taking cold, and begins with difficulty of swallowing and a sense of a foreign body in the throat, and is soon followed by chills and heat, and painful viscid expectoration; it commonly declines in 3 or 4 days under simple antiphlogistic treatment and astringent gargles; if the inflammation does not subside, the swelling largely increases, often threatening suffocation, which is sometimes

avoided only by the puncture or spontaneous rupture of the abscess. The enlargement of scrofulous and chronic inflammation requires a similar treatment, with the addition of tonics and alteratives, detergent gargles, stimulating and astringent applications, and, as a last resort, excision by the bistoury or a special instrument called tonsillotome. A noisy respiration during sleep in scrofulous children in many cases will indicate chronic enlargement of the tonsils. They are also the seat of phosphatic calculi, and from their mucous follicles are often cast out soft and fetid concretions.

TONSTALL. See TUNSTALL.

TONSURE (Lat. *tondo*, to clip), the name given to a mark distinguishing the clergy of the Roman Catholic and the eastern churches from the laity, and formed by cutting off a portion or the whole of the hair from the head. During the first 5 centuries the tonsure of the clergy was entirely unknown, and the practice of shaving the head or wearing the hair too short is in fact condemned in priests by Jerome and others of the fathers. But in the latter part of the 5th century the monks began to clip the hair in a conspicuously deforming manner, or to shave the entire head, partly in order to show their contempt of the world, partly for the express purpose of exposing themselves to ridicule. From the monks the tonsure gradually passed over to the secular clergy, and in the 6th century it began to prevail throughout the church. Different forms were in use in the national churches of Europe. The tonsure of the Roman church, also called *tonsura Petri*, consisted in shaving the entire head and leaving only a circular crown of hair. This form was soon adopted in Spain, France, and Germany. Pope Gregory II., in 721, made it obligatory for all priests under the penalty of excommunication, and in Spain it was regarded and enforced as a mark of orthodoxy, in distinction from the tonsure of the heretics, who used to shave only a small circular part of the occiput. Later, however, this custom of the heretics prevailed again in Germany and other northern countries from climatic reasons and is still in use. Many regulations with regard to the shape of the tonsure were made in the course of centuries, but they often came to be disregarded. The clerical crown must be preserved by repeated trimming when necessary, and the ecclesiastical law provides that it be enlarged as the wearer rises in ecclesiastical station and dignity. The priests of Scotland and Ireland adopted, until the 8th century, a tonsure in the shape of a crescent on the forehead (*tonsura Sancti Jacobi* or *Simonis Magi*), which horrified the Roman missionaries, and had to give way to the Roman form. The tonsure of the eastern churches, in ancient times, consisted in shaving the entire head (*tonsura Pauli*). A complete history of the tonsure is given in Thomassin's *Vetus et Nova Ecclesia Disciplina*.

TONTINE, a kind of life annuity originated by Lorenzo Tonti, a Neapolitan, who published

his scheme and introduced it into France about the middle of the 17th century. The subscribers were divided into 10 classes according to their ages, or were allowed to appoint their representatives, who were thus classed, and an annuity was apportioned to each class according to their age, the survivors having the benefit of an increased annuity as their associates died, and the last survivor receiving the entire annuity of the class till the close of his or her life. The first association of this kind was founded under the administration of Cardinal Mazarin in Nov. 1658, and was called the "Royal Tontine." The total sum paid in was 1,035,000 francs, in 10 classes of 102,500 francs each. The subscription was 800 francs, and every subscriber received the interest of his investment until the death of some member of the association increased the dividend to the rest, and after the death of the last subscriber it reverted to the state. This project was not successful, nor were two others subsequently proposed by Tonti. In 1689 Louis XIV., finding his finances embarrassed, authorized another of 1,400,000 francs divided into 14 classes, according to age, from children of 5 years to adults of 70. In 1726 the last survivor of the 13th and 14th classes was the widow of a poor surgeon who had invested in two tontines her little capital of 300 francs, and who enjoyed at her death, at the age of 96, an income of 73,500 francs. Tontines were again resorted to by the French government in 1733 and 1734; but in 1773 they were interdicted as a measure of finance. In 1791 a tontine called the *Caisse Lafarge*, on a more extended scale, was established under private management; but by a gross blunder or fraud, the interest promised was an impossible one, and the subscribers, whose united contributions amounted to 60,000,000 francs, never received even simple interest, and the entire capital was lost in the disasters of the time. In England tontines have been occasionally resorted to as a measure of finance, the last opened being in 1789, on which £42,032 interest was still paid in 1859. In the United States tontines have never been made a revenue measure by the government; but in several cities there have been private annuities of this kind. A tontine building was erected in Wall street, New York, in 1792-4, 208 shares of \$200 each being subscribed by an association of merchants. In Albany, New Haven, and some other cities, buildings have been erected on the same plan.

TOOELE; a W. co. of Utah territory, bordering on Nevada territory, intersected by tributaries of Humboldt river; area, about 10,000 sq. m.; pop. in 1860, 1,008. The surface in the E. and W. is mountainous, and the Humboldt mountains cross the W. end from N. to S. Along the streams there are several fine valleys of extraordinary fertility and beauty, but the mountain regions are rough and unproductive. Fremont's route to the Pacific traverses the county. Capital, Tooele.

TOOKE, JOHN HORNE, an English political leader and philologist, born in Westminster, June 25, 1736, died March 18, 1812. He was the son of John Horne, a poulterer; but as his father had become wealthy, he was educated at Westminster school, at Eton, and at Cambridge university, became an usher in a school at Blackheath, and much against his own wishes, but in obedience to his father's will, took orders and obtained a curacy in Kent. His preference was so strong for the law, that in 1756 he entered as a student at the Middle Temple; but in 1760 he returned again to the church, and was ordained priest, and for 8 years discharged the duties of that office in the chapelry of New Brentford. He then went to France as travelling tutor to the son of Elwes the miser. In 1765 he began his political life by writing a pamphlet in favor of Wilkes and his party; and on a second tour to the continent he formed at Paris an intimate acquaintance with that politician. During these travels he gave up his clerical profession, and, with the exception of a short time after his return, never resumed it. He took an active interest in political matters, especially in securing the election of Wilkes from Middlesex, and in the agitation which that event created throughout the kingdom. He claimed the authorship of the celebrated reply to the king made by Beckford, then lord mayor of London, in 1770. (See BECKFORD, WILLIAM.) In 1769 he was one of the founders of the society for supporting the bill of rights; but its financial affairs involved him in a quarrel with Wilkes, which affected his popularity. In 1771 he received, after considerable opposition, his degree of M.A. from the university of Cambridge, and in consequence of his quarrel with Wilkes was attacked by Junius, against whom he defended himself with unexampled success. In 1773, designing to study law, he formally resigned his living. In resisting with great vigor, and as was thought at the time with great success, an enclosure bill, which according to custom was to be hurried through the house of commons, he gained the favor of Mr. Tooke of Purley, who assured him that he should be his heir; but, though in 1782 he changed his name to Tooke out of regard for his patron, he never received more than £8,000 from the property. He bitterly opposed the American war, and published an advertisement for a subscription for the widows and orphans of the Americans "murdered by the king's troops at Lexington and at Concord." The ministry prosecuted him for libel, and the trial took place at Guildhall in July, 1777. The defence was conducted by himself, but he was found guilty and sentenced to one year's imprisonment in the king's bench, and a fine of £200. During his confinement he published his celebrated "Letter to Mr. Dunning," in which he critically examines the case of the King vs. Lawley, which had been used as a precedent against him on his trial. The discussion rendered necessary some philological

criticisms upon the prepositions and conjunctions of the English language, as he declared that he had been made "the victim of two prepositions and a conjunction," which particles he calls "the abject instruments of his civil extinction." After his release from imprisonment in 1779, he applied for admission to the bar, but was rejected on the ground of being a clergyman. His prospects of professional success were therefore at an end. Embittered still more against the government, he published in 1780, in conjunction with Dr. Price, a pamphlet entitled "Facts," severely reflecting upon Lord North and his prosecution of the American war, addressed to landholders, stockholders, and others. Soon afterward he retired from London to a farm in Huntingdonshire; but there he caught an ague which disgusted him with agricultural pursuits, and he returned to the city and plunged once more into political life. In 1786 appeared the first part of his "*Эсеа пропедевта, or the Diversions of Purley*," a strange combination of etymology, metaphysics, and politics, which has exercised a marked influence on English philology. The object of Tooke was to prove that all parts of speech, including particles, could be resolved into nouns and verbs; and that all words expressing operations of the mind, however delicate, were originally applied to objects of external perception. According to Bunsen, "he ably developed, among some doubtful speculative theories, very pregnant views respecting the origin of inflexions, suffixes, and formative words, a most important part in the comparative analysis of languages." In 1787 he published "A Letter to the Prince of Wales" in regard to his supposed marriage with a Roman Catholic. In 1788 appeared a pamphlet from his pen entitled "Two Pair of Portraits," in which he drew a contrast between the two Pitts and the two Foxes, not much to the credit of the latter. In 1790 he was a candidate for the representation of Westminster, against Fox and Lord Hood, and, though spending nothing, polled 1,700 votes. In 1794 he was tried for high treason, mainly on the ground of his participation in the action of the "Constitutional Society," in which the society for the support of the bill of rights had been merged shortly after his quarrel with Wilkes. During the proceedings he conducted himself with great firmness and courage, and was acquitted. He was defended by Gibbs and Erskine, to whom he dedicated the second volume of his "Diversions of Purley," which appeared in 1805. In 1796 he became again a candidate for parliament from Westminster, but was again unsuccessful, though polling 2,800 votes. In 1801 he obtained a seat in the house, being returned by Lord Camelford for the nominal borough of Old Sarum. This was a strange proceeding for so strenuous an advocate for parliamentary reform; but the decision of that parliament that a clergyman could not thereafter sit in the house of commons disqualified him from obtaining any

position in future. The latter years of his life were spent at Wimbledon. He was never married, but left several illegitimate children, to one of whom he bequeathed his property. His life was written by A. Stephens (2 vols. 8vo., 1813).

TOOKE. I. WILLIAM, an English clergyman, born Jan. 18, 1744, died in London, Nov. 17, 1820. In 1771 he became minister of the English church at Cronstadt, and in 1774 chaplain to the factory of the Russian company at St. Petersburg, and remained in that situation until 1792, when he returned to England. His most important works are: "A Life of Catharine II." (8 vols. 8vo.); "A View of the Russian Empire" (8 vols.); and "A History of Russia from the Foundation of the Empire to the Accession of Catharine II." His other works are chiefly novels, miscellaneous essays, and translations. II. THOMAS, an English political economist, son of the preceding, born in St. Petersburg in 1774, died in London, Feb. 28, 1858. In 1838 he published "A History of Prices and of the State of the Circulation from 1793 to 1837, preceded by a brief Sketch of the State of the Corn Trade in the last two Centuries" (2 vols. 8vo.). Four additional volumes were afterward published, bringing down the work to the year 1856. III. WILLIAM, brother of the preceding, born in St. Petersburg in 1777, studied law, and for many years practised as solicitor in London. He edited anonymously in 1804 the poetical works of Churchill, republished in 1844. In 1855 he published "The Monarchy of France, its Rise, Progress, and Fall" (8vo.).

TOOLA, or TULA, a central government of Russia, bounded by Moscow, Riazan, Orel, and Kaloga; area, 11,772 sq. m.; pop. in 1856, 1,125,517. The surface is generally flat. The most important rivers are the Oka, Upa, and Don, the two latter of which are connected by the Ivanovska canal, which forms part of the system that unites the Baltic, Black, and Caspian seas. The soil is fertile, and about $\frac{1}{2}$ of the surface is cultivated. Iron and woollen and linen goods are manufactured.—**TOOLA**, the capital, is situated on the Upa, 107 m. S. from Moscow; pop. about 35,000. It has an extensive cannon foundry and manufactory of arms for government, established by Peter the Great in 1717, and upward of 800 private workshops for the manufacture of firearms and cutlery.

TOOMBS, a W. co. of Minnesota, bordering on Dacotah territory, bounded S. by the Mstinka river; area, about 700 sq. m.; pop. in 1860, 40.

TOOMBS, ROBERT, an American statesman, born in Washington, Wilkes co., Ga., July 2, 1810. He studied 3 years at a college in Georgia, and then went to Union college, Schenectady, N. Y., where he was graduated in 1828. Afterward he studied law at the university of Virginia, and commenced practice in his native place. In 1836 he served under Gen. Scott as captain of volunteers in the Creek war, in 1837 was elected to the state legislature, and with

the exception of 1841 continued a member of the lower house until 1845. In that year he was elected to the federal house of representatives, and served in that body until 1858, when he became a member of the U. S. senate, and at the expiration of his first term was reelected. In both houses he served on various important committees, and was a prominent member of the extreme southern party, and after the election of President Lincoln was one of the most active in persuading Georgia to secede. On Nov. 15, 1860, he made a speech at Milledgeville, Ga., in opposition to Alexander H. Stephens, in which he strongly advocated secession; and on Jan. 7, 1861, he made an impassioned address in the senate in favor of the adoption of that course by the southern states. On Jan. 19 the state of Georgia passed its secession ordinance, and on the 28d Mr. Toombs withdrew from the senate. He was a member of the confederate congress which met at Montgomery, Ala., on Feb. 4. On Feb. 18 Jefferson Davis was inaugurated provisional president of the seceded states, and on the 21st appointed Mr. Toombs his secretary of state. In September of the same year he was succeeded in this office by Robert M. T. Hunter of Virginia. In entering public life Mr. Toombs belonged to the whig party, but about 1850 he went over to the democratic.

TOORKISTAN, or TURKESTAN, an extensive region of central Asia, so called from its being the original seat of the Turks or Toorkomans, in the wider sense of the appellation, and sometimes called Tartary, from the numerous Tartar tribes which roam over it. The name is usually restricted to the territory lying between Mongolia and the Caspian sea, and having Siberia on the N., and Persia, Cabool, the Punjab, Cashmere, and Thibet on the S. It is divided into two distinct countries by the Bolor Tagh, the western comprising several independent khanats, and known as Independent Toorkistan, the eastern nominally subject to China, and usually called Chinese Toorkistan. —**INDEPENDENT TOORKISTAN** is bounded N. by the Russian Kirgheez territory and Russian Soongaria, E. by Chinese Toorkistan and Cashmere, S. by the Punjab, Cabool, and Persia, and W. by the Caspian sea. Its area is somewhat vaguely estimated at 770,000 sq. m., and its population at 6,000,000. It is divided into a number of independent and often hostile khanats, of which the principal are Kafiristan in the S. E., Koondooz and Budukhsan in the E., Khokan in the N. E., Bokhara and Khiva in the central portion, and Toorkomania, or the south-western Kirgheez steppe, along the shores of the Caspian sea, in the W. Bokhara is the largest town, and is usually regarded as the capital of the country, though possessing no control over the remoter khanats. The other towns of importance are Khokan, Khojend, and Tashkend in Khokan; Khuloom and Koondooz in Koondooz; Khiva, Koongrad, and Shurookhs in Khiva; Samarcand,

Karshee, and Urastepeh in Bokhara; and Kaundaish and Tohitral in Kafiristan. The principal rivers are the Jihoon or Amoo-Daria (the ancient Oxus), which bisects the country, and discharges its waters into the sea of Aral; the Sir-Daria (Jaxartes), which with its numerous affluents drains the northern plain and enters the sea of Aral near its N. extremity in Siberia; the Zerafshan or Zirjafshan, which, rising in the great plain of Pamir, flows W. through the centre of the country and falls into a small salt lake S. S. W. of Bokhara. Beside these there are numerous tributaries of the Jihoon, some of them rising in the Bolor Tagh and others in the Hindoo Koosh, which are themselves important rivers; among these are the Duwan or Pjandje, the Sharood, the Akserai and its branches the Soorahab and Farkan. The Caspian sea bounds the country on the W., and the sea of Aral at the N. is partly within its limits. There are also numerous small lakes, all of them salt, of which the Siri Kol, said to be the most elevated lake in the world, the Riag Kol, the Dsarik Kol, and the Kara Kol are the most important. Between the 39th and 41st parallels the continuation of the Thian-shan or Celestial mountains (which here cross the Bolor Tagh) extends in two parallel ranges to near the meridian of 66° E., called Aktan-Isfera and Tanglakyar; the two ranges are separated by the valley of the Zerafshan, and form the northern and southern watersheds of the country. N. there is a gentle slope from the Aktan-Isfera to the shores of the Aral, which is about 84 feet below the surface of the Black sea; and S. from the Tanglakyar there is a gradual descent to the broad valley of the Jihoon. In the S. E., where the Bolor Tagh unites with the Hindoo Koosh, the lofty plain of Pamir, said to be 15,600 feet in height on the shores of the Siri Kol, falls rapidly to the valley of the Oxus, near Koondooz. The valleys of the rivers are fertile, but the more elevated lands are exceedingly sterile. The northern plain is believed by geographers to have formed at some remote period a part of the bed of the ocean. In the upper valley of the Jihoon the productions of the temperate zone are mingled with those of a semi-tropical character. The Bolor Tagh and its western prolongations protect it from the cold winds of the N. and N. E., and the Hindoo Koosh from the hot blasts from the S. E. The climate is greatly diversified; on the northern plain the summer heats are intense, and the cold of winter equally so, while the spring and autumn are characterized by heavy rains and sudden transitions. In Bokhara the climate is pleasant, dry, and salubrious, but cold in winter, the Jihoon being frozen so that teams can pass over it. Snow lies about 8 months; there are frequent tornadoes. The soil in the valley of the upper Jihoon gives indications of a volcanic character, and the climate is influenced by subterranean heat. The geological formations of the country are in the mountainous districts secondary, on the

plains for the most part tertiary and alluvial. Gold has been found from time immemorial in the sands of the Jihoon; salt deposits are numerous; sal ammoniac occurs in its native state; and rubies, lapis lazuli, and other precious stones occur. The vast plains are almost entirely without forests, and the number of indigenous plants is small. Fruits are excellent and abundant; the melons of Bokhara are unrivalled. Rice, wheat, millet, rye, barley, maize, tobacco, hemp, and rhubarb are cultivated in the valleys. In the valley of the Jihoon silk is largely produced. On the Toorkomanian steppe hardly any thing will grow except on the banks of the rivers. The number of animals is not great. There are several species of rodents, of which the mouse is the most abundant. In the valley of the Jihoon the buffalo, wild horse, one or two species of antelope, the yak, argali, leopard, wolf, fox, and hare are found; in the sterile plains are bats, tortoises, and lizards; scorpions are common, and the plague of locusts sometimes destroys the crops. There are no singing birds, but plovers, wild pigeons, and water fowl are abundant. There are but few fish; a species of dogfish called *lukha*, without scales, is found in the Jihoon, and attains sometimes the weight of 600 lbs.—The inhabitants of Independent Toorkistan are of several different races. The larger portion of them are Toorkomans proper, or Usbecks, as they are frequently called, and this region has been for many centuries their home. On the Toorkomanian steppe and in some of the other khanats there are considerable numbers of Kirgheez and some Nogai Tartars. In Kafiristan (Turkish, "land of the infidel") the inhabitants are of pure Caucasian race, and call themselves "brothers of the Firinghees" or Europeans; their language is Medo-Persian. The Tanjiks, or Tadjiks, who are numerous in the towns, are thought to be of Persian or Arabic origin, and speak pure Persian. There are also some Jews. The prevailing religion is Mohammedanism, and the greater part of the tribes are Sheehs; according to Dr. Wolff, however, there are one or two tribes of Soonnees, and some Soofees or mystics. The Kafirs and some of the Tartars are not Mohammedans, but worshippers of the Dalai lama. The Toorkomans are a fierce, haughty people, given to deeds of rapine and plunder, irascible and violent, but usually truthful and hospitable. They are generally hostile to foreigners. The people of the towns are less bold and daring, but more crafty and deceitful. Few travellers have visited the country, and of these few the greater part have paid for their temerity with their lives. Stoddart, Conolly, Moorcroft, Guthrie, and A. Schlagentweit thus perished.—The commerce of the country, especially of the towns of Bokhara and Khiva, is considerable, and is conducted entirely by means of caravans. Native productions form but a small part of this commerce; but these towns are the convenient

entrepôts of the products of Russia, Persia, Afghanistan, India, and the Chinese empire, which these nations exchange with each other, and hence enjoy a large carrying trade. Bokhara alone employs 8,000 camels in this trade. The manufactures of the country consist chiefly of some silk and cotton stuffs, sabres, knives, and other weapons. The exports are cotton, mostly from China, wool from Thibet, fruits, hides, sheepskins, and silk. The imports are muslins, brocades, sugar, shawls, and white cloths from India; European manufactured goods from Russia; porcelain, musk, tea, rhubarb, and cotton from China; and wool from Thibet. The government is despotic, but the khans are controlled by the Koran and by the influence of the priests.—CHINESE TOORKISTAN is bounded by the Siberian province of Tomsk, Mongolia, Thibet, Cashmere, Independent Toorkistan, and Russian Soongaria. Its area is variously estimated at from 500,000 to 800,000 sq. m., and its population at from 1,000,000 to 3,000,000. It is divided into two provinces by the Chinese, the one N. of the Thian-shan or Celestial mountains, which pass through its centre from E. to W., being called Thian-shan-pe-lu or Soongaria (see SOONGARIA), and the division S. of those mountains Thian-shan-nan-lu. Its principal towns are Yarkand, the capital, Ili or Guldja, Kashgar, and Aksu. The country on three of its sides is bordered by lofty mountain ranges; the Kuen-lun mountains form its southern boundary, the Akai bounds it on the N., and the Bolor Tagh separates it from Independent Toorkistan. On the E. the great central desert of Asia, Gobi, divides it from the inhabited portions of China and Mongolia. Thus walled in by mountains and desert, it is a country so little accessible that it is almost as much an unknown region to European travellers as central Africa. The southern province, or Chinese Toorkistan proper, is an elevated plain drained by the Tarim and its 6 great tributaries, the Kashgar, Yarkand, Kurakool or Karakash, Khotan, Yarang-kash, and Kena, all entering it from the S., and 3 or 4 of less size from the N. This great and remarkable river, over 1,500 miles in length, rises in the Kuen-lun and Bolor Tagh mountains, several of its affluents having their source in small lakes in those mountains, and, draining the entire province, discharges its waters into two small lakes, Lop-nor and Bostrog-nor, in the W. part of the great desert. The whole of this province, as well as the desert, forms a deep basin without outlet, the streams all running toward the centre, which is estimated to be about 1,280 feet above the level of the sea, and toward which the plateau slopes in every direction from the mountain crests, which are 15,000 to 16,000 feet in height. There are several small lakes. The Thian-shan chain is about 1,400 m. in length, nearly 100 in breadth, and rises for most of its length above the line of perpetual snow. Nearly $\frac{1}{4}$ of the surface is said to be unfit for cultivation, but

in the valleys of the rivers there are fertile lands, on which, under the intense heats of summer, many of the semi-tropical fruits and vegetables ripen. Considerable silk is raised, of good quality, and cotton, rice, wheat, millet, and leguminous plants, sesamum, hemp, and flax are cultivated extensively wherever the soil will permit. Grapes, pomegranates, melons, and other fruits are of excellent quality and in great abundance. The herds of cattle are very large, and afford the principal article of export. The wild animals are generally the same with those of Independent Toorkistan, but the argali is more plentiful. The two-humped or Bactrian camel is a native of the Thian-shan mountains. The minerals are gold, found in the mountain streams and in the Thian-shan mountains, iron, copper, nitre, sal ammoniac, sulphur, asbestos, agate, and the precious jasper, which is a monopoly of the Chinese empire. The inhabitants are mainly Toorkomans of the Usbeck tribe, who are said to be superior in character and intelligence to those of Independent Toorkistan. There are also in the towns Persians, Cashmerians, Mantchoos, Tunguses, and some Jews and Hindoos. Mohammedanism is the prevailing religion, but there is a clan of Usbecks on the Lop-nor who are not Mohammedans. The Mantchoos are generally worshippers of the Dalai lama. The Chinese authorities as well as the local hakim-beys forbid any Europeans to enter the country. The commerce of the southern province is extensive, its caravans trading with Peking, Lassa, Nijni Novgorod, and many intermediate points. Although the country nominally belongs to China, the Usbecks allow the Chinese only a moderate share in the general government, and do not permit them to interfere in their internal affairs or their religion.—Independent Toorkistan was known by the name of Turania to the ancient writers on Persia. It was the theatre of repeated terrible conflicts between the Iranian or Persian and the Turanian races, in the early ages of Persian history, and the Persian hero Jamshid figures as largely in some of these as Achilles in those of the early Greeks. The Iranians finally remained masters of the southern part of the country, and at the beginning of the historic period it was comprised in the Persian satrapies of Bactria and Sogdiana, which were afterward conquered successively by Alexander the Great, the Greek kings of Bactria, the Parthians, the later Persians, the Arabs, and the Tartars or Mongols of Genghis Khan and Tamerlane, under whom the Turkish and Tartar elements almost entirely replaced the Indo-European. The Tartars ruled over the southern portion till 1494, when their sultan Baber, driven out by the Turkish tribe of the Usbecks, emigrated to Hindostan, and there founded the Mogul empire. The Usbecks established a powerful monarchy, which continued about 160 years, but in 1658 separated into numerous independent khanats, in which condition it has since remained. Rus-

sia has recently acquired a strong foothold in western Toorkistan, and especially in Khiva, into which khanat an army of 17,000 Russians penetrated in 1854, and imposed upon the khan a treaty of alliance, by virtue of which a Russian ambassador resides at Khiva; 10,000 Khivan cavalry are placed under Russian officers, and paid by the Russian government; the Russians are authorized to maintain a garrison at Urghendj, and a Russian fleet is stationed in the Aral, and ascends the Jihoon at pleasure. The N. W. portion of the country, W. of the Aral, and forming a part of the Kirgheez steppe, is considered by the Russians as really a part of their empire, and they have erected 16 fortresses on the steppe to control it. Chinese Toorkistan has been from time immemorial divided into petty sovereignties, ruled by *khodjas*, or seigniors, and in the lower provinces its history consists only of a succession of squabbles between the chiefs of these, or the subjection of a part or the whole to the sway of some more powerful monarch from without. Of these conquests by foreign powers, the first of note was that effected by the Mongols under Genghis Khan. In 1758 the Mantchoo Tartars, then as now masters of China, subdued the province and divided it into 10 principalities, which they annexed to the Chinese empire. An attempt was made by the inhabitants in 1825 to throw off the Chinese yoke, but it was not successful. (See SOONGARIA.)

TOPAZ, a precious stone consisting of the following ingredients in 100 parts: silica, 34 to 39; alumina, 48 to 58; fluorine, 15 to 18.5. It is represented by the formula $3Al_2O_3, 2SiO_2$. Its specific gravity is 3.4 to 3.65, and its hardness 8, or between that of quartz and sapphire. It is generally yellow or colorless, but sometimes green, blue, or red. The yellow Brazilian topaz when heated becomes reddish, while the Saxon wine-colored topaz loses its color entirely. It crystallizes in the trimetric or rhombic system, the prisms generally having dissimilar extremities. When heated in the blowpipe flame it becomes covered with small blisters, while a coarse variety called physalite (Gr. *φυσαι*, to blow) swells up when heated. Several kinds of minute crystals of other minerals and two or three fluids were discovered by Sir David Brewster in the cavities of topaz. Like amber, it is very easily rendered electric by heat, &c., and retains the electricity for a long time. Its principal localities are the Ural and Altai mountains, Miask in Siberia, Kamtchatka, Villa Rica in Brazil, Cairngorm in Aberdeenshire, the Mourne mountains in Ireland, and Saxony; and in the United States, at Trumbull and Middletown, Conn., and at Crowder's mountain, N. C. Physalite occurs in Norway and Sweden in very large crystals, one of 80 lbs. having been found. The topaz is not very highly valued as a gem, though very fine specimens sometimes bring good prices. Tavernier speaks of one weighing 157 carats or about 625 grains, belonging to the

Great Mogul, which cost 181,000 rupees. The principal supply is from Brazil, which furnishes about 40 lbs. annually. The white and rose-red are the most valuable. The former are called by the Portuguese *pingos d'agua* (drops of water), and when cut closely resemble the diamond in lustre and brilliancy. The name oriental topaz is sometimes given to yellow sapphire (see SAPPHIRE), and a yellow variety of quartz is sometimes known as false topaz; but the first is much harder and the second softer than the real stone, while neither can be readily electrified by heat, like the topaz.

TOPHET, a spot in a fertile valley S. E. of ancient Jerusalem, called the valley (*Ge*) of Hinnom, or of the children of Hinnom, and hence Gehenna in the New Testament, and watered by the brook Kedron. It obtained an infamous reputation from being the place where the idolatrous Jews passed their children through the fire to Moloch, the god of the Ammonites; and according to a common derivation, the word comes from the Hebrew *toph*, a drum, because it had been customary to drown the cries of the victims by the noise of drums. At a later period it was used as a spot to throw the garbage of the streets, the carcasses of beasts, and the dead bodies of men to whom burial had been refused; and as a fire was kept constantly burning to consume all that was brought, the word was used metaphorically for hell. Some writers, therefore, identify the word Tophet with *tophteh*, which designates a burning or burial place.

TOPLADY, AUGUSTUS MONTAGUE, an English clergyman, born at Farnham, Surrey, Nov. 4, 1740, died in London, Aug. 11, 1788. He was educated at Westminster school and Trinity college, Dublin, entered holy orders, and obtained the living of Broad Hembury in Devonshire, where he resided for some years, but in consequence of ill health removed to London and preached in a chapel in Leicester square. He was a noted popular preacher, but his fame rests principally upon his controversial writings against the Methodists. He was the great champion of Calvinism in the church of England, and his works (6 vols. 8vo.) are almost exclusively devoted to the defence of the doctrines of Calvin, and are remarkable alike for logical clearness and rhetorical energy. He also edited for several years the "Gospel Magazine."

TOPLITZ, or TEPLITZ, a town near the N. W. frontier of Bohemia, in a valley of the Erzgebirge, celebrated for its thermal springs; permanent population about 4,000. There are 17 springs, varying in temperature from 118° to 119° F., considered very efficacious for gout, rheumatism, and kindred maladies. It contains a great number of houses for the accommodation of visitors, who in the season often reach 10,000. There are 8 classes of baths, some free to the public, others for the higher classes, and the third reserved for the use of the wealthy nobility and royalty. The palace of Prince

Olary with its beautiful surrounding grounds, containing a theatre and a large hall variously used as a dining, reading, and ball room, is open to the public. There are several hospitals, of which two are military, one Austrian and the other Prussian. The treaty of alliance between Russia, Prussia, and Austria, preceding the battle of Leipsic, was concluded at Toplitz in Sept. 1813.

TORENO, JOSÉ MARIA QUETPO DE LLANO RUIZ DE SAVAVIA, count of, a Spanish statesman and historian, born in Oviedo, Nov. 24, 1786, died in Paris, Sept. 16, 1843. In the rising of the Spaniards against the French in 1808 he took a strong interest, and was sent to England to negotiate for the assistance of that country. He became afterward, in spite of his youth, a prominent member of the cortes, but on the return of Ferdinand VII. was obliged to go into exile, residing successively in Portugal, England, and France. The revolution of 1820 recalled him to Spain, and until 1823 he occupied a conspicuous position in the cortes. The triumph of the absolutists caused him, however, to be banished a second time, and from this exile he did not return until the publication of the amnesty of 1832. In 1834 he entered the cabinet as minister of finance, and after the resignation of Martinez de la Rosa in 1835 he succeeded him as minister of foreign affairs and president of the council; but his growing unpopularity and the intrigues of Mendizabal forced him in September of that year to resign. On the breaking out of the revolution of La Granja in Aug. 1836, followed by the proclamation of the constitution of 1812, he retired to Paris, but after a few months was permitted to return to Spain, from which the revolution of Barcelona again drove him, and during this exile he died. In 1827 he began at Paris a history of the Spanish war of independence, which is the great Spanish work on that subject; it is entitled *Historia del levantamiento, guerra y revolucion de España* (5 vols. Madrid, 1835-'7; best ed., 4 vols. 8vo., 1848).

TORFÆUS, or TORMODUS, the Latin name of an Icelandic scholar, whose real name was Thormond Thorveson, born in Engre in 1640, died in 1719. He received a liberal education, and Frederic III. of Denmark in 1660 made him interpreter of Icelandic manuscripts, and in 1662 sent him to Iceland to collect manuscripts, in which he was eminently successful. In 1667 he was appointed keeper of the royal collection of antiquities, but in consequence of killing a man in self-defence was obliged to give up the post. In 1682 he was appointed royal historiographer, and held this position until his death. He wrote numerous works, some of which still remain in manuscript. One of the most important is his *Historia Rerum Norvegiarum* (4 vols. folio, Hafnia, 1711). He first published the northern sagas respecting the discovery of America.

TORGAU, a fortified town of Prussia, on the left bank of the Elbe, 70 m. S. S. W. from Ber-

lin, in the administrative district of Merseburg and province of Saxony; pop. about 9,000. There are manufactories of linen and woollen goods and a brass foundry in the town. The tomb of Catharine von Bora, the wife of Luther, is here. In 1525 the Lutherans concluded a league with the elector Frederic the Wise of Saxony at Torgau. In 1530 they settled there some articles which served as the basis of the Confession of Augsburg, and in 1576 published a confession of faith called the "Book of Torgau." In 1760 Frederic the Great defeated the Austrians near this town. Being held by the French during the campaign of 1818, it was besieged by an army under Tanentzien toward the close of that year, and capitulated in December. The siege was marked by an unparalleled destruction of life from typhus fever among the garrison and in the vast hospitals.

TORGET, a small island of Norway, off the S. W. coast of Nordland, lat. 65° 30' N. It is noticeable only for the mountain of Torghatten, which rises almost perpendicularly from the water to a height of over 2,000 feet, having on its summit a small lake, and being completely perforated near its centre by an immense cavern 6,000 feet long and 600 feet high. The mountain is cleft in many places almost to its base, apparently by earthquakes. The Norwegians have a tradition that their ancient kings were accustomed when crowned to visit this cavern, and prove their strength by hurling a javelin through it.

TORLONIA, the name of a family of Italian bankers raised to the rank of Roman princes. **GIOVANNI TORLONIA**, who died at Rome Feb. 25, 1829, as duke of Bracciano, by extensive enterprises and successful investments, laid the foundations of the fortunes of his family. His eldest son, **MARINO**, born in Rome, Sept. 6, 1796, inherited the duchy of Bracciano, which however was sold to the Odescalchi family. The second son, **CARLO**, born Dec. 18, 1798, was commander of the order of the knights of St. John, and became a partner in business with the youngest brother, **ALESSANDRO**, born June 1, 1800. The last named, who bears the titles of prince of Civitella-Oesi, duke of Oesi, and marquis of Roma-Vecchia, has increased to an enormous amount the property left by the father. He has devoted his wealth in large measure to constructing magnificent buildings, collecting works of art, and carrying on new and useful enterprises in Rome and its neighborhood.

TORNADO. See **HURRICANE**.

TORNEA, a river of northern Europe, having its source in the lake of Tornea-Trask, in the province of Pitea, Sweden. Its course is at first S. E. to the Russian line, thence S., forming the boundary between Russia and Sweden, and finally falling into the gulf of Bothnia after a course of about 240 m. Its principal affluents are the Lanio and Muonio, both from the left. It runs between high banks, and has a very rapid current for most of its course, but below Carl Gustav is somewhat wider. It forms the

fine cataract of Juliae between Vojakkab and Kukkola.

TORNEA, a town of European Russia, in the district of Uleaborg, Finland, capital of the circle of Tornea, situated on the left bank of the Tornea river, near its mouth, in the gulf of Bothnia; lat. 65° 50' 8" N., long. 24° 14' E.; pop. 800. It has a considerable trade in timber, salmon and other fish, feathers, reindeer skins, butter, tar, furs, tobacco, and spirits. The town was founded in 1620 by the Swedes, and captured in 1715 and 1809 by the Russians, who finally held it by the treaty of Frederikshamn. The boundary between Russia and Sweden was definitively settled by a treaty made here in 1810. The observations of Maupertuis and the other French academicians for determining the figure of the earth were made at Tornea in 1736-'7. After the middle of June the place is frequently visited by travellers who come to witness from the summit of a neighboring mountain the spectacle of the sun remaining for a number of nights above the horizon.

TORONTO (formerly **YORK**), a city of the British province of Canada, formerly the seat of the provincial government, and still the capital of Upper Canada. It is situated in York co., on a well protected bay of Lake Ontario, 40 m. from the W. extremity of the lake, 80 m. by a direct line N. of Fort Niagara on the opposite shore, 360 m. W. S. W. from Montreal, 165 m. W. S. W. from Kingston, and 45 m. N. by E. from Hamilton; lat. 43° 34' N., long. 79° 20' W.; pop. in 1861, 48,821, of whom 18,767 were natives of the province, 12,441 of Ireland, 7,112 of England, 2,961 of Scotland, 2,081 of the United States, and 807 of other countries. The city is regularly laid out on a plateau which extends backward from the lake a distance of 3 m. to a ridge of high ground, forming the N. boundary of the town and the connecting village of Yorkville. The present corporation limits include an area of 3,000 acres. The chief business thoroughfares are King street, running E. and W. parallel with the lake, from 100 to 200 yards N. of the bay; Yonge street, running at right angles with King street, and by its extension in a direct line N. constituting the old line of communication with Lake Simcoe, 35 m. distant; and Queen street, occupying part of the old Dundas road, so called after the governor of that name, and which formed the great line of communication between the East and the West before the days of railroads. Spadina avenue, St. George's square, and Jarvis, Gerard, and Church streets are in part built up with large and elegant private dwellings. Toronto is distinguished for the number and costliness of its places of public worship, numbering in all 27, exclusive of various religious meeting houses which do not claim the designation of churches. The principal ecclesiastical edifices are St. James's, the cathedral church of the Anglican communion, a fine Gothic structure, erected in

1852 at an expense of \$180,000; Knox's church, belonging to the Free Presbyterian body, remarkable for the symmetrical proportions of its spire; Cooke's church, a large edifice, belonging to the same body; Gould street chapel, formerly belonging to the United Presbyterians; the Richmond street Wesleyan Methodist church; Zion chapel, Congregational; St. Michael's cathedral, Roman Catholic; and the Unitarian chapel in Jarvis street. The religious division of the city in 1861 showed the following proportions: church of England, 14,125; Roman Catholics, 12,185; established Scotch church (Presbyterian), 2,898; Free church (Presbyterian), 2,480; United Presbyterians, 1,281; Wesleyan Methodists, 5,022; Episcopal Methodists, 1,149; New Connexion Methodists, 280; other Methodists, 525; Baptists, 1,288; Congregationalists, 826; other bodies, 3,118. Toronto is a bishop's see of both the English Episcopal and Roman Catholic churches. The benevolent institutions are numerous and well sustained both by public endowments and private subscription. They include among others the general hospital, which had originally an endowment of public lands, and receives beside a yearly grant from the provincial parliament; the lunatic asylum, supported by a special tax, and affording accommodation to 800 patients; a house of industry, dependent in part on municipal support; the house of providence, supported by the Catholics; the house of the sisters of mercy; and the Protestant orphan asylum, dependent also on private benevolence. The educational institutions embrace the educational department for Upper Canada, occupying in conjunction with the normal and model schools a handsome building and ample grounds in the centre of the city; the Toronto university and University college, for the use of which a building, the most elaborate and conspicuous in the province, was provided in 1859 at a cost of \$420,000; and the Upper Canada college, an imitation in a modified form of Harrow and Rugby schools in England, intended as a preparatory school for the University college. Beside these, there is a grammar school supported by a public grant and the fees of students; 8 ward common schools, established on the free principle, and maintained at an average cost for the last 5 years of \$21,800; and 4 separate schools belonging to the Roman Catholics, which share in the public educational grant in proportion to the numbers attending. Of the denominational collegiate institutions there are several which have a high provincial standing. Among these are: Trinity college, belonging to the church of England; St. Michael's college, Roman Catholic; and Knox's college, the theological institution of the Free church Presbyterians. There are 2 daily and 5 weekly newspapers, beside several scientific and theological magazines. The banks properly belonging to the city are the bank of Upper Canada and the Toronto bank; beside these, there are branches of the bank of Mon-

treel, City bank, Ontario bank, bank of British North America, the Quebec bank, and the Banque du Peuple. In addition to the public buildings already noticed, there are the mechanics' institute, the St. Lawrence hall and market, the court house for the county and city, the crystal palace (an agricultural exhibition building), and the old parliament house. Surpassing these, however, in the elaborateness and beauty of the design, is Osgoode hall, the temple of the law for the whole of the western province. In this building the sittings of the chief courts of the province are held, including the queen's bench, the common pleas, the court of chancery, and the court of error and appeal. The benchers of the law society have their headquarters here; and out of the funds belonging to this corporation, and by means of an additional government grant, the hall in its present costly shape was erected.—The city is municipally divided into 7 wards, each of which returns annually to the common council two aldermen and two councilmen, making the whole number 28. The mayor is also elected annually. The two classes of municipal representatives sit and deliberate in one chamber; but the powers of the councilmen are not magisterial, like those of the aldermen and the mayor. The principal public improvements effected under municipal control are a thorough system of drainage, extensive water works supplied from the lake, and a large esplanade fronting the bay, partly designed as an open promenade ground, and partly for the use of the railways which concentrate at this point. The cost of the esplanade is estimated at \$700,000. The railways which connect Toronto with other points are: the Grand Trunk, running eastward to Kingston, Montreal, Portland, and Quebec, and westward direct to Sarnia, Port Huron, and Detroit, and by branch to London; the Great Western, connecting the city with Hamilton, London, Detroit, and Niagara; and the Northern, running to Collingwood on Lake Huron, and thence connecting by steamboats with Chicago and the great grain depots of the West.—The principal manufactures consist of cabinet ware, iron rails, for which a factory was established in 1850, and various founderies, distilleries, and flouring mills. For the establishment of a cotton mill a corporation grant of land was made in 1860; the progress of this undertaking, however, was arrested by the difficulties which the civil war in the United States (1861-'2) threw in the way of the procurement of cotton. The average value of property, real and personal, from 1855 to 1861, was \$23,172,800. The direct shipping trade of the port includes imports of coal from Lake Erie ports, *via* the Welland canal; of general merchandise from Lewiston by the Niagara river and from Rochester by the lake; and of heavy goods, chiefly hardware and groceries, from Montreal. The exports are chiefly of manufactured lumber and flour, and of wheat and other grain to Oswego, Ogdens-

burg, and Montreal. The imports from 1855 to 1861 averaged annually \$4,157,182, and the exports \$1,605,652.—Toronto has only been known by that name since 1884, when it was incorporated as a city. In 1791, when a parliamentary constitution was first given to the province of Upper Canada, the capital was placed by royal proclamation at Niagara Point, near the mouth of the river of that name; and at that time the site of the city of Toronto was occupied by a few families of Mississauga Indians. In 1794 the place was selected by Governor Simcoe as the site of a town, and early in the present century it was selected as the seat of government in place of Niagara. Its distance from the frontier by the land route was its chief military recommendation; for it has no natural defences, and was easily reduced by the invading American force in the war of 1812-14. On economic grounds, its central position made it eligible as the seat of the executive and the chief courts of law. But it was probably even still more recommended by the commercial advantages of a natural harbor, which is formed with but little artificial improvement by the deposits of a sluggish stream entering the lake on the eastern boundary of the city, and on which the lake sands have accumulated, until a peninsula has been formed, extending in a curving line S. and W. for a distance of 8 m., and thus creating a fine basin of smooth water for the protection of shipping. So late as 1817 the population of the town of York was only 1,200, and in 1826 it was but 1,677. Two years after its incorporation as a city its population had increased to 9,652. It suffered seriously by the insurrection of 1837, being the head-quarters of the rebellion, and also by the removal of the seat of government to Kingston, after the union of the provinces in 1841. In 1849 the seat of government was temporarily restored, and again in 1855; and its progress from the first named period, 13 years ago, although decided, has been necessarily fluctuating, on account of the changes incident to the alternating system of locating the seat of government for the united province.

TORPEDO, the popular name of the electric rays or skates of the family *torpedinida*. They were called *vapay* by the Greeks and *torpedo* by the Latins; the Germans call them *Krampe-Fisch*, the French *torpille*, and the English cramp fish and numb fish. The body is smooth and rounded; the tail short and thick, cylindrical at the end and keeled on the sides; teeth conical, sharp, and crowded; ventral fins immediately behind the pectorals, dorsals generally 2 and on the tail, and the caudal subtriangular. The electrical apparatus, which has given the name to the family, is arranged in 2 masses, one on each side of the skull, between this and the base of the pectorals; it is composed of a multitude of perpendicular gelatinous columns or hexagonal prisms, separated by membranous partitions containing a fluid, freely supplied with blood, and receiving very nu-

merous nervous filaments from the par vagum and trifacial nerves. There are about 20 species, arranged in 7 genera, in the seas of all parts of the world; the best known are the species of the Mediterranean and the W. coast of Europe, and of the Atlantic coast of North America, all belonging to the genus *torpedo* (Dum.), in which the mouth is crescentic, the teeth not extending outward beyond the margin of the lips, and spout-holes distant from the eyes, with a circular fringe around the opening. The common torpedo of the Mediterranean (*T. marmorata*, Rud.; *T. Galvanii*, Bonap.) is sometimes of a uniform brown color, but generally marbled or spotted with darker; it rarely attains greater dimensions than 4 by 2½ feet, or a weight over 50 lbs. The spotted torpedo of the same sea (*T. ocellata*, Rud.; *T. narké*, Risso) is of a yellowish red color, with 1 to 5 large, rounded, grayish blue spots, surrounded by a brownish circle, with a few whitish dots, and grayish white below. One (or both) of these species occurs on the W. coast of Europe as far as Great Britain, and also, it is said, in the Persian gulf and Indian ocean; they feed on small fish, keeping on the mud or sand at the bottom; their flesh is eaten along the Mediterranean. Their electrical powers were well known to the ancients, and their shock was recommended by them for the removal of various pains, especially of the head—the earliest example of the application of electricity as a remedial agent. The use of this battery is probably both for defence and for the purpose of obtaining food, their motions being very slow; Mr. Couch is of opinion that animals killed by it, as by lightning, decompose more quickly and are more easily digested than they otherwise would be, such a preparation of the food being perhaps necessary in an animal with an intestinal canal shorter than the stomach; the shock is said to be less powerful than that of the electrical eel, though it may be felt through a line, pole, or even stream of water. This apparatus is analogous to the galvanic pile, and its anatomy has been investigated by John Hunter ("Philosophical Transactions," 1778), who counted 1,200 columns in a very large fish, about 150 plates to the inch; the ends of the prisms are in contact with the skin above and below, and each cell of the vertical series is lined with an epithelium of nucleated corpuscles.—The American torpedo (*T. occidentalis*, Storer) attains a length of about 4½ feet and a width of 8; it is dark brown above with a few black dots, and white beneath; eyes very small, and spout-holes directed outward and a little forward. It is found on the coast of Massachusetts about Provincetown in the autumn, and at Chilmark, near Gay Head, in the spring; many run ashore on the sandy beaches, and some are occasionally taken by seine, hook, and harpoon; the liver contains an excellent burning oil, 1 to 2 gallons from a common-sized fish; it is also used externally and internally for cramp. In a dissection given

in the "Proceedings of the Boston Society of Natural History" (vol. v. p. 21, 1854), Prof. J. Wyman estimated the number of plates at between 250,000 and 800,000, about 1,200 prisms in each battery, each 1 to 2 inches in height, and containing about 100 plates to the inch; the interval between the plates was filled with an albuminous fluid, 90 per cent. water, containing common salt in solution; the ganglia from which the par vagum nerves arise are larger than the brain itself, indicating the great nervous power supplied to the battery.—For details on this subject see *ELECTRIC FISHES*, and *Leçons sur les phénomènes physiques des corps vivants*, by O. Matteucci (Paris, 1847).

TORPEDO, in military science, a machine for blowing up ships, invented by Mr. David Bushnell of Connecticut in 1776, and named by him the torpedo, or "American turtle," from the resemblance in the form of a portion of the original one he made to two upper tortoise shells. These shells were placed together, and were sufficiently capacious to contain the operator and air enough to support him half an hour. The portion occupied by him was a close pipe in the part corresponding to the head of the animal, and in this he was seated upright in a position to use an oar for propelling the machine through the water. In the other end was placed a quantity of lead for ballast to keep the machine upright, and an aperture was there made, controlled by a valve for admitting water, so as to descend when desirable; and two brass forcing pumps furnished the means of ejecting this water, when it was necessary to ascend. To the after part of the machine was attached a powder magazine, hollowed out of oak timber, large enough to contain 150 lbs. of powder, together with the apparatus used for firing it. A screw belonging to it, managed by the operator, was used to secure it to the vessel which it was intended to destroy. A gun lock connected with clockwork was contained in the magazine, and the latter was set in action on casting this off; and according to the time the clockwork was set to run, the fire was struck by the gun lock. An attempt was made with this apparatus to destroy the *Eagle*, a 64-gun ship, commanded by Lord Howe, lying in New York harbor, which failed from the operator striking as he supposed a bar of iron in the bottom of the ship, which prevented the entrance of the screw; and as daylight appeared before he could return to shore, he cast off the powder magazine near Governor's island, which in one hour's time exploded, throwing up a vast column of water, to the great alarm of those on board the ship, who were entirely ignorant of the cause. Mr. Bushnell made several other attempts in 1777 to destroy English shipping by this method; and in one of these against the frigate *Cerberus*, lying at anchor near New London, Conn., his machine, which in this case was attached to a rope with a view of its drifting against the frigate, was drawn on board a schooner near by,

and on exploding blew this vessel to pieces. Another device of Mr. Bushnell was to charge a large number of kegs with powder, and an apparatus so arranged as to cause this to explode whenever the kegs, set adrift above the shipping, came in contact with other objects. Some of these, floating down the Delaware in Dec. 1777, exploded among the ice, and one blew up a boat; and altogether they occasioned the greatest consternation among the British seamen at Philadelphia, who manned the wharfs and shipping, and discharged small arms and cannon at every thing floating down with the ebb tide. This is known as the "battle of the kegs."—Torpedoes upon a somewhat similar plan were next devised by Robert Fulton in 1805, and their efficiency was exhibited near Walmer castle, then the residence of Mr. Pitt, in the destruction of a strong-built Danish brig of 200 tons, which was submitted to his experiments. In Aug. 1807, he performed a similar experiment in New York harbor. His torpedoes were submerged cases containing gunpowder with the lock and clockwork for exploding. Two cases, one at each end of a line, were dropped ahead of a ship at anchor, so as to be caught across her hawser by the middle of the line, thus letting each case swing against a side of the ship. (See FULTON.) Fulton published an illustrated treatise on torpedoes, entitled "Torpedo War and Submarine Explosions" (New York, 1810).—In the Crimean war the Russians employed torpedoes of an ingenious construction, which were anchored in the channels leading to Cronstadt. These were magazines held at a certain depth from floating buoys, to which they were attached by a rope. A flexible lead pipe closed at the upper end reached up to the buoy from the magazine, containing a small glass tube holding sulphuric acid, which would cause an explosion on coming in contact with the preparation of chlorate of potash, &c., occupying the lower portion of the lead tube and connected with the gunpowder in the magazine. The concussion caused by a vessel striking the buoy would break the glass tube and thus produce the explosion.—Torpedoes have been resorted to as a means of preventing the passage of U. S. vessels through southern waters, during the civil war of 1861-'2. At Columbus, Ky., as many as 4 varieties of these machines were found, 3 of which were intended for use under water, and a fourth for exploding under ground. They were of formidable dimensions, some made of cast iron and some of boiler plate iron, some designed to explode on being struck by a heavy body, and others to be fired by galvanic batteries contained in subterranean apartments. Notwithstanding the great labor and ingenuity expended on torpedoes, they have proved of no service in warfare; and their success is dependent upon so many contingencies that the probabilities are very small of their taking a place among the established weapons of war.—TORPEDONS, in pyrotechny, are explosive prepara-

tions made of various compounds, such as are described in the article FULMINATES.

TORQUATUS, TITUS MANLIUS IMPERIOSUS, a favorite hero of Roman story, who flourished during the last half of the 4th century B. C. In his youth he is said to have been of dull intellect, and brought up in great privacy in the country; upon which account in 862 the tribune M. Pomponius, in an accusation against the elder Manlius, hated by the people for his haughtiness, charged him also with being an arbitrary and tyrannical parent. As soon as the young Manlius heard of this, he hastened to Rome, and compelled Pomponius to withdraw his accusation; and this act of filial devotion so pleased the Romans that he was made the same year military tribune. In the last invasion of the Gauls, he gained great distinction by fighting with a gigantic enemy on the bridge over the Anio upon the Salarian road. Successful in the combat, he took from the neck of his slain opponent the chain of gold (*torques*) and put it around his own, and from this circumstance was called Torquatus by the soldiers, a name which was handed down to his posterity. In 858, though he had not yet held the consulship, he was made dictator in order to carry on the war against the Oerites and Etruscans, and in 849 was again made dictator for the sake of holding the comitia. He was consul in 847, 844, and 840. In this last year his colleague was P. Decius Mus, and the two were appointed to carry on the war against the Latin league. While in the plain of Capua an order was issued forbidding all single encounters with the enemy; but Titus Manlius, the son of Torquatus, having been challenged by Mettius Geminus of Tusculum, fought with his antagonist and slew him. Returning to the camp, he laid the spoils at his father's feet; but Torquatus, turning away from him, assembled the soldiers in the prætorium, and in their presence his son was beheaded. The young men of Rome from that time regarded Torquatus with abhorrence, and the memory of the occurrence was long preserved in the phrase *Manliana imperia*. In this campaign a great victory was gained over the Latins at the foot of Mt. Vesuvius, and Torquatus returned to Rome in triumph. According to the *Fasts*, he was dictator again in 820, but the dates of his life vary in different authors.

TORQUEMADA, TOMAS DE, a Spanish inquisitor-general, born in Valladolid about 1420, died in 1498. He became a member of the order of the Dominicans and prior of the monastery of the holy cross in Segovia, and in 1488 was made inquisitor-general for Spain by Ferdinand and Isabella, in which position he was confirmed by the pope on Oct. 17. From him the inquisition received its thorough organization. Four tribunals were established at Seville, Cordova, Jaen, and Ciudad Real (later transferred to Toledo), and a code promulgated by which the Spanish inquisition was afterward governed. Jews and Moors were expelled under his con-

trol, and he multiplied *autos da fé* to such an extent that Pope Alexander VI. was under the necessity of intervening and giving him 4 colleagues to moderate his zeal.

TORRES VEDRAS, a town of Portugal, 25 m. N. from Lisbon, on the left bank of the Sizardo; pop. 8,826. It is partly surrounded by its ancient walls, and an old fortress still remains. In the vicinity are an aqueduct with Gothic arches and the noted convent of Varra-tojo. It is chiefly remarkable as giving name to the defensive lines erected by Wellington in 1810 on a range of heights in its neighborhood, which took nearly a year for their completion, and which set the army of Masséna at defiance.

TORREY, JOHN, M.D., LL.D., an American botanist and chemist, born in the city of New York in 1798. After taking his medical degree at the college of physicians and surgeons, New York, he devoted his attention exclusively to botany and chemistry. He was one of the earlier members, and at one time the president of the New York lyceum of natural history, to the "Annals" of which he largely contributed, both in the department of botany and that of mineralogy. In 1817, at the request of this society, his earliest publication was prepared, viz., a catalogue of the plants growing within 80 miles of New York (1819), a work still interesting as indicating the changes which have taken place in the flora of this now densely populated region in less than half a century. In 1824 he published the first volume of the "Flora of the Northern United States," and in 1826 his "Compendium" of the same; but before the second volume of the larger work was ready for the press, the natural system of Jussieu had so far superseded the artificial system of Linnaeus, that he abandoned the work and suffered his materials to accumulate till 1838, when, assisted by his former pupil, Dr. Asa Gray, he commenced the more extended "Flora of North America." In this work he has proceeded as far as the close of the great order *compositae*, completing one volume and two thirds of a second; but the pressure of other engagements, and the vast accumulation of new genera and species, brought to light by the exploring expeditions across the continent, have compelled delay in its further prosecution. Meantime Dr. Torrey has prepared the botanical part of the reports of the natural history survey of the state of New York (2 vols. 4to., 1843-4), and in connection with Dr. Gray has examined and described, in the successive government volumes on the exploring expeditions, a large portion of the new plants, shrubs, and trees collected by those expeditions. During all this period he has also been actively engaged in chemical and mineralogical investigations, and in responsible collegiate duties. In 1824 he was appointed professor of chemistry in the West Point military academy, but resigned that post in 1827 to accept the professorship of chemistry and botany in the college of physicians and surgeons in

New York, which he held until 1854; and on his resignation he was appointed professor emeritus. He was also elected in 1838 professor of chemistry at Nassau Hall, Princeton, N. J., and held that position till 1851. In 1853, when the U. S. assay office was established in New York, he was invited to become its assayer, which office he still holds. He has been for some years a trustee of Columbia college, and has taken an active part in promoting its plans for extending the curriculum of instruction and organizing a post-graduate course. It is in the department of botany that Dr. Torrey's labors have been most important and influential. His first considerable work inaugurated a new era for botanical science in North America, and in all that has been effected for its advancement during the last 40 years he has borne a leading part.

TORRICELLI, EVANGELISTA, an Italian mathematician and philosopher, born at Piancaldoli in Romagna, Oct. 15, 1608, died in Florence in 1647. He received a mathematical education in a Jesuit school at Faenza, which he completed at Rome. Some tracts written by him upon the dialogues of Galileo excited the venerable philosopher's attention, and he invited Torricelli to Florence, who 3 months later, upon his death, became his successor in the academy as professor of mathematics. His greatest discovery is that of the barometer, of which his own account is given in his *Lezioni accademiche* (Florence, 1715). He published *Opera Geometrica* (4to., Florence, 1644).

TORRIGIANO, PIETRO, an Italian sculptor, born in Florence about 1475, died in Seville in 1522. He studied his art in company with Michel Angelo in the gardens of Lorenzo de' Medici; but having in a fit of jealous rage assaulted his fellow pupil and permanently disfigured him by a severe blow upon the nose, he was obliged to leave Florence. For several years he was a soldier, but resumed his chisel, and executed small bronze figures for some Florentine merchants, whom he accompanied to England. He succeeded in attracting the notice of Henry VIII., for whom he executed a number of works, the most important of which was the tomb of Henry VII. in Westminster abbey, called by Lord Bacon "one of the stateliest and daintiest in Europe." In 1519 he visited Spain, and received several commissions. Having executed for the duke of Arcos a copy of a "Virgin and Child" which had been much admired, he was so enraged at the small sum which he received for it, that he broke the work in pieces. He was immediately imprisoned in the inquisition on a charge of sacrilege in destroying a figure of the Holy Virgin, and was condemned to death, but avoided a public execution by starving himself.

TORSION BALANCE. See **BALANCE**.

TORSK, or **TUSK**. See **CUSK**.

TORSO (It.), literally, the stump of a cabbage, lettuce, or similar plant, but commonly used to denote the trunk of a statue, from which the head, arms, and legs have been bro-

ken off. The most celebrated torso in existence is that in the Belvedere at Rome, which Michel Angelo made the subject of profound study. It was found in Rome in the latter part of the 15th century, and is ascribed to Apollonius, an Athenian sculptor who flourished in the 1st century B. C.

TORSTENSON, LENNAERT, count of Ortlea, a Swedish general in the 30 years' war, born in Forstena, Aug. 17, 1603, died in Stockholm, April 17, 1651. In 1618 he became a page at the court of Gustavus Adolphus, and in this position remained 4 years, accompanying the king in his travels and campaigns. In one of the battles against the Poles he was sent by Gustavus with orders to a subordinate general; but perceiving as he rode that the enemy had changed his movement, he changed the order on his own responsibility in accordance with the new position of affairs. The king from that time placed great confidence in him, and as captain of his body guard he accompanied him in 1630 on his expedition to Germany. In these campaigns he gained great distinction, especially in the direction of the artillery arm of the service, was present at the battle of Leipsic or Breitenfeld in 1631, contributed materially to the passage of the Lech in 1632, and in the contest near Nuremberg the same year was taken prisoner. He was carried to Ingolstadt, one of the strongest fortresses of Bavaria, and the incarceration to which he was subjected was so severe as in a few months to destroy his health, and to leave him not only a confirmed invalid, but thenceforth liable to the acutest forms of disease. His release was finally effected by Wallenstein in exchange for Count Harrach. He was immediately placed by Oxenstiern at the head of an army corps, with which in 1633 he invaded Bavaria and captured Landsberg, but was obliged by ill health to resign his command to Marshal Horn and repair to Sweden. In 1634 he was made grand master of the artillery, and in this position he accompanied in 1635 Jacob de la Gardie, sent with an army of 20,000 men to act against the Poles in Prussia, and subsequently succeeded to the chief command. In the same year he also marched to the relief of Baner, and was with that leader in the campaign of 1636 and 1637. In 1639, acute disease compelling him again to return to his native country, he was there made a state councillor. When Baner died, by an express clause in his will he bequeathed the command of the army to Torstenson as the only one fit for the position; and in 1641 the latter accepted the charge with the rank of field marshal and generalissimo of the Swedish armies in Germany. His health was however so prostrated that his friends wished him to retire from the public service; but his only answer was: "I rather wish to die early than to survive myself." With a reinforcement of 8,000 men and a large sum of money he joined the confederates in the duchy of Luneburg, and soon reestablished discipline, restor-

ing confidence and content to the troops, who were suffering from want of pay and provisions, and threatened with the desertion of their allies. Directing his attack against the hereditary states of Austria, he marched through the territories of Brandenburg into Silesia, stormed Glogau, and on May 21, 1642, gained a great victory at Schweidnitz over the imperialist general Albrecht of Saxe-Lauenburg. Upon this success he pushed into Moravia, reduced a number of cities, and spread terror to the very gates of Vienna; but the superiority of the Austrian forces compelled him to retreat to Saxony, where he laid siege to Leipsic. Here he was attacked on Nov. 2 by the imperialist forces under the archduke Leopold on the plain of Breitenfeld, on the very spot where Gustavus had gained his great victory. This "second battle of Leipsic," as it is sometimes called, resulted after a terrible conflict in the defeat of the Austrians, with the loss of 10,000 men killed and prisoners; and Torstenson, again resuming the offensive, reduced all Saxony under his power, marched a second time into Moravia, and laid the country under contribution as far as the Danube. In the mean while the Danish government had entered into a secret alliance with Austria; and to punish this conduct, Torstenson, on the receipt of private orders from the regency of Sweden, suddenly broke up his camp in Moravia in Sept. 1643, and in December burst into Holstein, and within 6 weeks made himself master of the peninsula, unprepared for resistance, with the exception of Glückstadt and Krempe. The mildness of the winter, which prevented him from crossing on the ice, alone saved the islands. An imperial army under Gallas hastened to the relief of Denmark, with the design of shutting up the Swedes in the Cimbric peninsula; but Torstenson unexpectedly forced his way through into Germany. Gallas followed, but was himself surrounded, and on Nov. 23, 1644, was totally defeated at Jüterbogk in an attempt to cut his way through. Torstenson now advanced into Bohemia, and on Feb. 24, 1645, gained the great battle of Jankowitz, in which the imperialists were defeated with the loss of 8,000 men, and their commander Hatzfeld captured. This secured the submission of Moravia, and the Swedish general, obtaining the control of the Danube, took even the fortifications which covered the head of the bridge at Vienna. Deserted here by his allies, he was obliged to retreat into Bohemia, and there in 1646 his increasing infirmities obliged him to give up the command to Wrangel. He now returned to Sweden, where in 1647 he was raised to the dignity of a count, and in 1648 was intrusted with the government of several provinces, and was also made one of the 8 councillors of the kingdom. Torstenson, though so weakened by the gout as to be under the necessity of being carried in a litter, was the most rapid in movement of the military leaders of his time; and it was said of him that

while his body was confined to earth, his mind was free as air and his enterprises had wings.

TORT (Lat. *torvus*, from *torqueo*, to twist), in law, a private or civil wrong or injury, in contradistinction from a crime against the public or the state, but not technically including breaches of contract or other agreements. Torts are injuries or infringements of the civil rights that belong to individuals considered merely as individuals, while crimes are private wrongs which affect the community and so invade and violate the rights of society. The distinction between private injuries and public wrongs seems to be much dependent on the constitution and positive laws of civil society. So long as the harm done by an offence is limited to the single individual against whom it was directed, the offender commits only a private injury or a tort; but if the act, though immediately concerning an individual, disturbs the public order or safety and welfare, then the positive law interposes and elevates the hitherto private offence to the degree of a crime or of a misdemeanor. In some cases the private offence is entirely merged in what the legislature declares the public wrong. Thus robbery is clearly an injury to private property, and, so far as the injured party is concerned, might be in all cases compensated by damages. But the law long ago declared robbery to be in all cases a great public mischief and offence, never to be expiated by compensation; and ever since the crime has entirely overshadowed the tort. In other cases, the injury may be both a public and a private one, or at once a tort and a crime or misdemeanor. For example, the commission of a battery subjects the aggressor to a public prosecution as a disturber of the peace, while the party beaten may have his separate civil action for damages. Libel and nuisance are other examples of this twofold character.—As wrongs are privations or infringements of rights, so torts, being private wrongs, are infringements of private rights, or the rights of individuals. These rights respect either the person or the property. In the former class is included the right of personal security, in respect as well to the body as to the health and the reputation, and the violations of this right in one or other of these respects bear the names battery, assault, nuisance, slander, libel, and malicious prosecution. In this class is included also the right of personal liberty, which is violated by false imprisonment. Rights of property, real or personal, may be infringed by trespasses in various degrees, by waste, conversion, and fraud, and the more incorporeal of these rights by nuisance and by infringement of patents and copyrights and rights in trade marks. These several names of torts have been applied by long usage of the law to prescribed and well determined offences. But beside these, there are many torts not specifically designated or classed, because they do not affect well defined classes of rights, but vary with the peculiar

circumstances of every case.—When one alleges that a tort has been committed against him, he must show at all events that he has been wronged. The mere fact that the act complained of has injured the plaintiff, does not entitle him to claim indemnity unless the act were also a breach of a legal obligation between the parties, resting either on their express agreement, or on the general policy and rules of the law. That, for example, my neighbor builds a wall just before windows of mine, to which it is conceded I have no prescriptive right as ancient lights; or that in a street occupied by private and costly dwellings my neighbor chooses to use his house for a shop, or convert it to other uses offensive to me and yet constituting no nuisance, gives me in neither case ground for action, however considerable the actual injury or damage may be to me. The reason is, that I have not been wronged; it is a case of what the law calls *damnum absque injuria*, damage but no wrong; no legal right of mine has been violated. The law favors, though it does not adopt in its whole extent, the principle of morals that every one ought so to use his own rights as not to injure others. On this ground it is disposed to recognize a wrong when it sees injury or damage, at any rate so far as to require him who has done the damage to justify his act. So when the wrong is clear, the law is disposed to presume injury even though it be not apparent. Every wrong, says Judge Story, imports damage in the very nature of it; and if no other damage is established, the party is entitled to nominal damage. To use Sir John Holt's quaint and familiar illustration: "If a man give another a cuff on the ear, though it cost him nothing, nay, not so much as a little *diachylon*, yet he shall have his action." It is on this principle, that, without proving any actual damage, one who has a right of way may maintain an action against an intruder, or one whose lands are flowed against him who constructs a dam so as to set back the water. So a voter can sustain suit against the authorities for refusing his ballot, even though his candidate was elected. These are cases of legal wrongs, infringements of legal rights; and even if no actual damage be proved, the injury or damage is the presumption of the law. To this class also belong those cases of torts in which the legal wrong consists in the doing of a mischievous act which is only likely to prove injurious to others, or even in the doing of a legal act in such a careless or negligent manner that injury may probably result; for carelessness of the rights of others is in itself morally wrong, and by the construction of law is legally wrong when injury results from it.—Property can be the medium of torts or wrongs to the owner only in virtue of its representing him. It must in some way be directly impressed with his personality, before any trespass upon it will assume the character of an injury to him. That this is the view of the law

will appear from the consideration, on the one hand, that generally a wrong can be done to one through his property only when that is in his possession, or at least when he has an uncontested right to the immediate possession of it; or in other words, when his lands or his goods are part and parcel of himself, just like his limbs, only not so intimately and corporeally; and, on the other hand, from the consideration that the actual possessor of land for instance, even if he have no title, may yet maintain trespass for an intrusion against any one except the real owner, or him who has the right of possession. In short, the law inquires less about the complainant's ultimate rights, than whether his personality has been intruded upon. The commonest form of a tortious intrusion upon real property is called trespass *quasi clausum fregit*, or for breaking and entering upon the plaintiff's close. A higher offence against a person, in respect to his property, than mere encroachment on his possession, is that which consists in a usurpation of the property itself. An injury of this nature is most likely to happen in respect to personal property, and one of the most frequent actions for torts of this nature is that of trover. One may be further injured in his rights of property by the effect of threats, mistake, or fraud. In the last respect, for example, an action lies when one knowingly utters a falsehood to the plaintiff with the design to deprive him of a benefit and to acquire it to himself, and damage naturally results from the plaintiff's belief. But it is not always necessary to show that the defendant intended to defraud the plaintiff particularly. Thus one who makes a false recommendation of another, representing him to be solvent and trustworthy, and with the purpose of obtaining credit for him, is liable to any one who gives credit to the report and thereby suffers injury.—Passing from rights in corporeal and tangible things to rights which, though incidental in great part to corporeal property, are yet in themselves incorporeal and less specific or definable, we meet the tort of nuisance, which consists in injury to the more natural rights of individuals, and the tort of infringement of patent and copyrights and rights to trade marks, which are rights created and assured by the positive law.—In our examination of torts we have thus far considered persons only in their natural capacity. It is obvious that new rights arise and new wrongs become possible when the individual is clothed with an artificial character; when, for example, he becomes a sheriff, a magistrate, or other public officer. The new functions with which he is invested give him capacity for doing official wrongs; and these, as they affect private individuals, form new classes of torts.—A corporation is liable like an individual for its torts. Thus a turnpike company has been held to answer for injuries resulting from defect in a bridge, and a canal company for damages caused by a want of repair of its locks. A

corporation is liable for the wrongful acts of its officers, either where they are expressly authorized to do the acts, or where they were done *bona fide* in pursuance of a general authority. But, generally speaking, it cannot be held for any offences by its servants that are properly, in any case, only personal acts, like malicious prosecution, slander, or false imprisonment. But a corporation has been held responsible for an assault and battery committed by a servant acting under its authority. Banks are liable for the frauds and mistakes of their officers, committed within the proper limits of the business; as in respect to entries in their books or to accounts of deposits. So they are liable, without special agreement, for the default of an agent or correspondent in respect to collections which the bank has specifically undertaken for its customers. But, according to the weight of authority (for the rule is not well established), a bank would not be answerable, upon such default, for losses on a note, payable at a distant place, and received by it, in the ordinary course of business, as the mere local medium of communication with the real collecting agent, provided always that the bank has used good faith and reasonable care in the selection of such agent or correspondent. Municipal corporations are liable in tort for the same acts that would warrant an action against individuals, if such acts are done by the authority of the corporation or of a branch or bureau of its government, authorized to act in the premises to which the particular act relates. Thus they must answer for nuisances on their lands, for injuries resulting from the want of care or skill on the part of a public surveyor, or from the careless performance of street grading, or from neglect to repair streets, sewers, and drains. The civil liability of municipal corporations for injuries sustained by defects in the highway is generally determined by express statutes. They usually require the way "to be kept safe and convenient," and whether this requirement has been complied with or not, is a question for the jury.—The various kinds of torts, and of actions for tort, are treated specifically under the titles ASSAULT, ATTACHMENT, COPYRIGHT, EXECUTION, LIBEL, INJUNCTION, PATENTS, SERVANT, SHERIFF, SLANDER, TRADE MARK, TRESPASS, TROVER, &c.

TORTOISE, the popular name of the chelonian reptiles whose habits are wholly or in part terrestrial and fluviatile, including all the studinata except the marine species or turtles—that is, the *amyda* of Oppel as distinguished from the *chelonii* of the same author. Their general characters have been given under TESTUDINATA. The sub-order *amyda*, according to Prof. Agassiz, comprises the following 7 families, not equally related to each other: *trionychida* or soft tortoises, *chelyoida* (the *matamoras*), *hydraspidida*, *chelydroidea* or snappers, *cincornida* or mud tortoises, *emydoidea* or terrapins, and *testudinina* or land tortoises. Of the very numerous species here included, space

will permit the mention of only a few of the typical forms in the above order of families. Duméril and Bibron divide the *amyda*, according to habitat, into *cherrites* or land tortoises, corresponding to *testudinina*, and *elodites* or marsh tortoises, including all the other families except the *trionychida*, which form their *potamites* or river tortoises. Though some pass nearly all their life in the water, none are entirely aquatic, and none can swim unsupported for great distances; when in the water, they usually remain at the bottom, and seldom swim freely except when seeking or leaving it. Their locomotion is a kind of walking, the weight being about equally distributed on the front and hind limbs, which have nearly the same development, the motions of each pair alternating with each other. The shield or carapace is more symmetrical than in the turtles; the feet are always distinct from the legs, and movable upon them; the toes are either separate and short, or united by a web capable of expansion and contraction; the limbs can generally be withdrawn under the carapace, and the head wholly or partially. The tortoises rank higher in the order than the turtles.—In the *trionychida* the carapace is flat, thin, and oval, and very incomplete, the ribs united only on the median line, and extending thence to the margin like spokes of a wheel; it is covered with a tough skin, flexible on the margins; neck long and flexible; head pointed, and terminating in a long leathery snout; jaws covered with a horny sheath, and the lips fleshy; feet short, broad, and strong, 5-toed and fully webbed, 8 of the toes with claws; limbs only partially retractile and moving horizontally; skin loose and free about the neck and limbs. Of the 8 North American genera, all occur to the north of the 21st isothermal line, while those of the old world are found only to the south of that line; the American species extend over the whole continent east of the Rocky mountains, and as far north as the great lakes and the upper St. Lawrence; the foreign species are found in the warm regions of S. E. Asia and Africa. The oldest geological deposit in which any of this family has been discovered is the greensand of New Jersey. They are active species, preferring the muddy bottom of shallow water, sometimes lying concealed in the mud with only a part of the head exposed, taking breath from time to time by stretching up their long neck and raising the tip of the snout above the surface; they can remain under water more than half an hour at a time, rarely going on land, where their movements are awkward; in the water they move rapidly, striking suddenly at objects by means of their long neck; they prey principally on fish, seizing also frogs, small birds, and young alligators and lizards; the species found in the Nile is very destructive to young crocodiles; they have been known to attack persons while bathing. They are very wary, but are frequently caught by hooks baited with a live fish; their

flesh is highly esteemed. Their eggs are numerous, spherical, and very brittle; they are deposited on sandy shores near the water in April and May, and the young appear in July. The genus *trionyx* (Wagler), equivalent to *cryptopus* (Dum. and Bibron), is peculiar to Asia and Africa, the species of this country formerly referred to it belonging to the genera *aspidonectes* (Wagler), *platypeltis* (Fitz.), and *amyda* (Ag.). The common soft-shelled tortoise of the northern states (*A. spinifer*, Ag.) attains a length of 14 inches; it is yellowish brown, beneath white, mottled, streaked, and dotted with black; a blunt keel along the median line slopes uniformly to the sides, and the anterior margin is furnished with spines; it is found from Lake Champlain to Pennsylvania and west to the Missouri and Mississippi rivers; its flesh is very delicate. Other species of this genus are found in the south-western states. The common *trionyx* of the southern states (*P. ferox*, Fitz.) much resembles the northern species, and has been generally confounded with it; the head, however, is shorter, wider, and higher, descending steeply to the long proboscis, which, as in all the family, is not an organ of smell, but rather of touch and for respiratory purposes, in the former sense acting like the snout of the moles and shrews; nostrils terminal and vertical; mouth large but short; jaws strong, blunt, and adapted for crushing; it attains a length of 18 and a width of 16 inches; there are well defined black dots on the back, and the lower surface is white; it is found only from Georgia to western Louisiana. In the *A. mutica* (Fitz.), found from New York to Pennsylvania and west to the tributaries of the Missouri and upper Mississippi, and in Lakes Erie and Ontario, the head and jaws are longer and narrower; the carapace is smooth, and the lower parts uniform whitish; it is light brown above with minute dark spots, and has a well marked depression along the middle of the back; it feeds principally on aquatic larvae; it attains a length of 12 and a width of 10 inches. Very large species of this family were brought here from western equatorial Africa by Mr. Du Chaillu.—The *chelyoida* somewhat resemble the preceding family, but the head and neck are more retractile and furnished with numerous membranous fringes and lobes of singular form; the carapace is flattened, covering about $\frac{1}{3}$ of the neck, thick, completely ossified and regularly divided into plates; head broad and flat, turned to one side under the shield; eyes far forward, directed upward and outward; snout long and membranous; jaws weak, neither sharp-edged nor pointed; mouth wide with fleshy lips, adapted for taking soft and minute prey; the jaws may be opened and shut quickly and continuously like a duck's bill; legs short and stout, not retractile, and feet broad, 5-toed, with long, sharp claws, only 4 on the hind toes. There is only the single genus *chelys* (Dum.), and a single species, the *matamata* (*C. matamata*, Dum.), attaining a length of 2 or 3 feet; it

inhabits the stagnant waters of tropical South America, feeding on fish; it is captured for its excellent flesh.—The *hydraspidida*, containing the genera *platemya*, *podocnema*, &c., were united to the chelyoids by J. E. Gray, the two forming the *elodites pleurodères* of Duméril and Bibron. The neck is long, the head retractile or bent laterally under the shield; in some the skull presents the union of the temporal and parietal bones to form a broad roof over the temporal region, as in marine turtles, combining thus the family characters of the two sub-orders; Prof. Agassiz thinks that *podocnema* will be found to agree more closely with the earlier geological types than with any other, and that the group of *pleurodères* bears the same relation to other testudines that the marsupials do to ordinary mammals. The sexual differences are so great that they have been mistaken for specific; the tail of the male is much the longest, and in this sex there are sharp asperities between the joints of the hind legs; the colors are also different. This group is foreign to the United States, and mostly South American, a few being found in Africa and Madagascar.—The *chelydroida*, which have been sufficiently described in the article *SEMPER TURTLE*, are thoroughly aquatic, and the lowest of the *amyda* except the preceding families; they are characterized by their keeled back, serrated margin, broad, flat, and imperfectly retractile head, narrow and cross-like sternum, and large tail. There is one species (*platysternum*, Gray) in China, and one of each of the genera *chelydra* (Schweig.) and *gypochelys* (Ag.) in North America; this is a very singular geographical distribution, especially as they are found only to the east of the Rocky mountains; they existed, however, in Europe in the miocene period. The eggs are usually spherical, but sometimes ovate; when hatched the young have a circular body.—The *cinosternoida* have a long and narrow body, the carapace rising to behind the middle, and thence descending steeply backward; the whole shield is ossified, covered with large horny scales, and as wide behind as in front, with a tendency of the edges to round up and turn inward; the sternum is less extensive than in the succeeding families, and the pelvis more movable, the former with an odd bone and divided longitudinally into two symmetrical halves; the tail is neither long nor strong enough to bear any of the weight of the body, and in the male ends in a horny nail; legs slender, feet short and round, toes freely movable and webbed, and the whole very flexible; head long behind and short in front of the eyes, pointed, with the small mouth underneath; alveolar ridge sharp, the lower jaw ending in a sharp point; neck long and slender; the plastron is sometimes hinged. In average size they are the smallest of the order, the least being about 4 and the largest 9 inches in length; all are American, and no trace of their fossil existence has been discovered; the

sexes are very different. They live mostly in water and in the mud, coming out to bask in the sun in places where they can readily drop into the water at the approach of danger; their food is principally animal, and their motions quick, though feeble and awkward; generally timid, they bite fiercely if attacked while feeding, like the insectivora among mammals. The colors are generally dark, sometimes with reddish, greenish, and yellowish tints. They lay 8 to 5 eggs, on the shore near the water, in holes dug by their hind feet; they are elongated, with a smooth and shing surface, thick, and brittle. In the common mud tortoise (*Thyrosternum Pennsylvanicum*, Ag.), the jaws are strong and cutting, and the mouth long and narrow; it is dusky brown above, yellowish dusky or brownish below; chin and throat dirty yellow, with the warts on the latter brighter; it is usually about $3\frac{1}{4}$ inches long, nearly 8 wide, and $1\frac{1}{4}$ high. It is found from Pennsylvania to Florida, and west to the Mississippi valley; the anterior and posterior parts of the sternum are movable on the central piece; it abounds in muddy ponds, feeding on small fish and aquatic insects and larvæ; it is a pest to anglers, seizing the bait set for better game; it has a slight odor of musk, but less so than the next species. The musk tortoise (*Orsothea odorata*, Ag.) has the nose projecting far beyond the end of the jaw, and the alveolar ridge sharp and cutting; the color above is black or dusky, clouded with brown, and dirty yellowish white below; a yellowish white line from the snout over each eye and along the neck; limbs dingy white below; it is about $8\frac{1}{4}$ inches long, $2\frac{1}{4}$ wide, and $1\frac{1}{4}$ high. It ranges from New England to Florida, and west to the Mississippi; the habits are like those of the mud tortoise; a favorite habitat is a Carolina rice field, where in the ditches it finds a plenty of small fish and tadpoles; it emits when alive a strong odor of musk. The genus *Cinosternum* (Spix) belongs in Central and South America.—The *Emydoidæ* are most numerous in species, over 50 being described, presenting great differences in size, structure, and habits. The body is ovate, swelling in the centre, the margin with a tendency to spread outward; the carapace is completely ossified and united by sutures, high and irregularly convex in all directions; plastron long and broad, and sometimes hinged; the jaws horny, without lips, and not terminating in long sharp points; head, neck, and limbs completely retractile; nostrils at the end of the snout, which is not prolonged into a process; toes long and webbed, or short and free, according as the habits are aquatic or terrestrial; skin of head, neck, limbs, and tail more or less scaly. They are principally aquatic, though some are terrestrial, the limbs moving horizontally while swimming, and walking being performed on the whole foot (as in plantigrades); they are generally of moderate size, the smallest being 4 and the largest (the aquatic) 15 inches in length. The food is both ani-

mal and vegetable, consisting of fish, worms, larvæ, berries, leaves, and grass; they are not ferocious, and are unable to catch an active prey; they are most abundant in warm regions. The eggs are laid in holes dug by their hind legs, the terrestrial species laying 2 to 7, and the aquatic 10 to more than 80; the shell is less calcareous and more flexible than is usual; the shape is oblong. The young are at first circular, growing more and more elliptical with age; the shield is not ossified till late in life. Though this family is most numerous in North America, there is not a single species described under the genus *emys* by herpetologists which belongs in it; the so called *Cistudo Blandingii*, corresponding to the *emys* of Europe, is the only representative here of Brongniart's genus; the others belong to various genera as established by Agassiz in vol. i. of his "Contributions to the Natural History of the United States" (1857). The genera *ptychemys* (Ag.), *trachemys* (Ag.), *malacoclemmys* (Gray), and *deirochelys* (Ag.) have been described under TERRAPIN. The common and handsome painted tortoise (*Chrysemys picta*, Gray) may be known by the yellow borders of the black dorsal scales, the blood-red blotches and lines on the marginal plates, limbs, and under part of tail, and the golden yellow sternum; hind toes fully webbed; there is a notch in the horny sheath of the upper jaw, the edge of each side projecting to form lateral teeth close together. It is found as far north as New Brunswick, through the eastern and middle states to South Carolina and Georgia; west of the Ohio it is replaced by the *C. marginata* (Ag.); it is about 6 inches long, $4\frac{1}{4}$ wide, and $2\frac{1}{4}$ high; it is most abundant in ditches and sluggish waters, spending most of the day basking in the sun; it is very timid, hibernates early, and is one of the first to appear in spring; it feeds on insects, worms, tadpoles, &c., and is very troublesome to anglers; it will survive only a few days out of the water. The speckled or spotted tortoise (*Nanemys guttata*, Ag.) is another very common species, distinguished by its yellow dots on a black ground, and its blackish sternum bordered with yellow; the edge of the upper jaw is straight, slightly notched in front, with the snout rounded; the neck and loose skin scaly. It is found from New England to the Carolinas, and to the east of the Alleghanies; it often comes on land, to feed on worms and orthopterous insects; it is about 5 inches long, 8 wide, and $1\frac{1}{4}$ high. The geographic tortoise (*Graptemys geographica*, Ag.) is so called from the network of reddish brown lines spread irregularly over the dark brown carapace, somewhat resembling the outlines of countries on a map; the head is very large, and the alveolar surface flat, smooth, and horizontal; upper jaw without a notch, and the end of the lower spoon-shaped; there is a ridge along the back. It is one of the most active and bold of the family, and is found from New York and Pennsylvania

to Michigan, Tennessee, and Arkansas; it is over 8 inches long, 6 inches wide, and 8 inches high, with a tail of 2½ inches. The sculptured tortoise (*Glyptemys insculpta*, Ag.) is a very common species in the northern states and as far south as New Jersey; the carapace is reddish brown, each scale with radiating yellow ridges, often smoothed down in old specimens; marginal plates and sternum yellow, each with a black spot at the posterior angle, and generally with concentric striae; limbs brick-dust color below; the upper jaw is in the form of a bill, arched downward and notched at tip, and the lower jaw arched upward; it is 8 inches long, 5 broad, and about 8 high, with a tail of over 2 inches; it passes long periods of time away from water. Blanding's tortoise (*Emys meleagris*, Ag.) is the only true species of the genus here; it is black above with numerous yellow spots, sometimes arranged in lines; below dusky yellow, each plate with a large quadrangular dark spot at the outer and posterior angle; the alveolar surface is narrow, and its horny sheath notched in front; the plastron is not united by suture to the carapace, and is hinged in the middle, the two parts being raised to meet it when the animal withdraws into its shell; the head is long and wide, and the mouth broad. The young are nearly circular, black and spotless above, and the scales granular; the sternum black with a white edge; they elongate rapidly with growth. It is found from New England westward to Wisconsin, being most abundant on the prairies, and very terrestrial in its habits; it is 8 inches long, 5½ wide, 8 high, with a tail of 2½ inches. The common fresh water tortoise of the south and east of Europe (*E. lutaria*, Merr.) is about 9 inches long, blackish above with interrupted light yellow stripes; it shuts its shell less close than the box tortoises; it feeds on aquatic insects, small fishes, tadpoles, slugs, &c.; its flesh is much esteemed, and in order to fatten it bread and tender herbage are supplied in parks adapted for the purpose. The box or checkered tortoise (*Cistudo Virginea*, Ag.; *C. clausa* and *Carolina* of other authors) has a rough and strong shell, generally of a light brownish color with very numerous bright yellow blotches and lines, more or less radiating, giving somewhat the appearance of tortoise shell; sternum usually yellowish with dark blotches; the head is long and very high, alveolar edge narrow, with upper jaw projecting downward like a beak; hind feet plantigrade; plastron with a hinge in the middle, so that the anterior and posterior portion can each be brought in contact with the carapace, and enclose the animal in a perfect box. It is about 6½ inches long, 4½ wide, and 2½ high; it is found from New England south to the Carolinas, and west to Michigan; it is entirely terrestrial, and a very poor swimmer; it is common in the pine barrens of the southern states, where it is called cooter and pine terrapin by the negroes; it feeds on insects and succulent plants, and is easily domes-

ticated. In the south and west are other species with only 8 toes.—In the *testudininae* or land tortoises the carapace is entirely ossified, very convex in the middle region, but well balanced; the plastron is broad, flat, and solid; openings for protrusion of limbs small and narrow; head, limbs, and tail completely retractile within the shell, and the plastron in some with movable lobes; the horny plates touch each other at the edges, and exhibit concentric lines of growth; head small and shielded, nose broad, and eyes far apart; alveolar margin with a sharp edge, and the jaws fitting closely by ridges and furrows; akin everywhere more or less scaly; toes mostly concealed under the skin, as far as the last joints, which are free and covered by flat sharp nails, usually 5 anterior and 4 posterior; feet short, stout, and somewhat clubbed; the great intestine is longer and the lungs larger than in any other testudinate, in relation with the greater convexity of the shell. They are most abundant in warm climates, and are the largest of the order, the great Galapagos tortoise being 3 to 4 feet long, the African conil (*psammobates radiatus*, Fitz.) 1½, the gopher 1, and the common European land tortoise 8 inches (the smallest of the family); here also belongs the fossil gigantic *colosuchelys Atlas* (Cautl. and Falc.), from the Sivalik hills, which must have measured nearly 18 feet in length, and found with the great extinct pachyderms which it so much resembled in gait and habits. It is singular that there are no tortoises indigenous to the British islands, though they might be easily naturalized there. All the American *testudininae* belong to the genus *xerobates* (Ag.). They live entirely on land, and when put into water walk on the bottom; the body is raised on the last joint of the toes, and the gait is firmer, more steady, and less slow than in any other tortoise. They are harmless, offering no resistance when attacked, trusting for protection to their shield, within which the head is drawn very far back, the neck being bent like the letter S and vertically; their food is exclusively vegetable, consisting of succulent plants and fleshy fruits. There are only 8 genera, but many species. In *xerobates* the front legs are compressed, and the feet have large flat nails, but not a plantigrade palm; the hind feet are plantigrade; the head is very broad, mouth wide, lower jaw high, and both with sharp ridges; the *X. Carolinus* (Ag.), or *testudo polyphemus* (Daudin), has been described under Gopher. In the African genus *kinixys* (Bell) the posterior part of the dorsal shield is movable downward, the hinge being between the 5th and 6th ribs; in *pyxis* (Bell), from the East Indies, the anterior part of the plastron is movable. In the European land tortoise (*testudo Graeca*, Linn.) the carapace is oval, somewhat widest and gibbous behind, marbled with black and yellow; plastron pale yellow with a wide blackish band down each side; legs short, and tail ending in a horny tip. It is found in Spain, Italy, Greece,

and other countries bordering on the Mediterranean; it has frequently been carried to England, where it has been domesticated and known to live more than a century. This is probably the species which, according to fable, Mercury found after an inundation of the Nile, and which from its carapace and dried tendons gave out a musical sound when struck by him, and thus led him to construct the *testudo* or ancient lyre, afterward presented to Apollo and the Muses.—The Galapagos tortoise (*megalocheilus indica*, Fitz.; *testudo elephantopus*, Harlan) is the largest of the order, frequently measuring 12 feet in circumference; the shell is very convex and of a deep brown color. It is very fond of water, drinking large quantities, and delighting to wallow in the mud like a pachyderm; some live in the mountains and others in the low lands of the Galapagos islands, and the latter in their journeys after water in the elevated regions have worn well beaten paths, which led mariners to the discovery of the much coveted springs, often at a great distance from the shore; they drink by immersing the head, up to the eyes, and swallowing great mouthfuls, about 10 per minute according to Darwin; their flesh is excellent, and largely used both fresh and salted, and a very clear oil is made from the fat. They feed on succulent plants and vegetables, and in captivity are fond of cabbage, lettuce, and marrows; they were formerly very numerous in these islands, and probably live for centuries; their gait is very slow, about 2 miles in 24 hours, though they have been known to travel 4 miles in the same time. The eggs are laid in October in the sand, and are about 8 inches in circumference; the young are devoured by birds of prey; in Great Britain, where numbers have been kept alive, they go under ground in November and reappear in the middle of April; many have been seen in the United States.

TORTOLA, one of the Virgin group of West India islands, belonging to Great Britain, lying between Virgin Gorda and St. John's, in lat. 18° 24' N., long. 64° 32' W.; pop. in 1851, about 10,000. It is 12 m. long by 2 to 4 broad, and has a rough and mountainous surface, rising to the height of over 1,600 feet. There are several bays, and on the N., at Tortola, the chief town, is an excellent landlocked harbor. It exports sugar, molasses, rum, and copper ore. This is the most important of the British Virgin islands, and is the seat of the lieutenant-governor and the administrative council. The climate is unhealthy.

TORTOSA (anc. *Dertosa*), a walled city of Catalonia, Spain, in the province of Tarragona, situated on the left bank of the Ebro, 48 m. S. W. from Tarragona; pop. 20,578. The town stands on the slope of a hill, and is entered by 3 gates; the streets are badly laid out, narrow, ill paved, and some of them very steep. There are several small squares, and the houses are generally well built. It has a Gothic cathedral, numerous churches, and 6 suppressed

convents. Cotton and linen goods, glass, earthenware, cordage, wax candles, leather, soap, brandy, starch, and baskets are manufactured. The river is navigable for vessels of about 100 tons, and a considerable trade is carried on. Quarries of valuable marble, known as Tortosa Jasper, are situated about 8 m. from the city.—Scipio conferred the privilege of a Roman *municipium* upon Tortosa. It was early taken by the Moors, but was wrested from them in 811 by Louis le Débonnaire. They afterward retook it, and it became the harbor of a nest of pirates. A crusade was proclaimed against it in 1148 by Eugenius III., and it was captured. The Moors made desperate efforts to retake it, but the Christian women defended the walls while the men sallied out and put the besiegers to flight. Many privileges were conferred upon the women in reward for the bravery displayed, and in 1170 the military order of La Hacha, or the Flambeau, was instituted for them. The French took Tortosa in 1798, and again in 1811, when Gen. Lilli was found guilty of cowardice and condemned to death for surrendering it, but was pardoned by Ferdinand VII.

TORTUGA (Span., "the turtle"). I. One of the Leeward islands, in the Caribbean sea, 55 m. W. from Margarita; length from E. to W. 15 m., breadth 8 m. It belongs to Venezuela. II. A small island lying off the N. W. coast of Hayti, in lat. 20° N., long. 72° 36' W.; length from E. to W. 22 m., breadth 5 m. III. An island in the gulf of California, 85 m. S. from the island of Tiburon.

TORTUGAS. I. A group of 10 islets or keys, also called the Dry Tortugas, at the entrance of the gulf of Mexico, 120 m. W. S. W. from Cape Sable, the extreme southern point of Florida. They are low coral islets, and partly covered with mangrove bushes. A lighthouse has been erected on Bush or Garden key; and in 1861-'2 refractory members of several volunteer regiments were sent thither to work upon the construction of Fort Jefferson. II. An island of the West Indies, off the N. E. coast of Cuba, from which it is only separated by a narrow channel called El Savirral. It forms the entrance to the harbor of Nuevitas, and is 26 m. long from N. W. to S. E. and about 6 m. wide.

TORTURE, properly, an infliction of severe pain upon an accused person to induce a confession of guilt, or upon a criminal to extort a revelation of his accomplices. The term is frequently used carelessly to designate severe and unusual punishment inflicted for crime, but improperly, as it is never spoken of by judicial writers as a punishment. By legal writers on the continent of Europe and the earlier English authors, the word *questio* (Lat. *questio*, a seeking) is used as a synonyme of torture; the object being a search for the truth in regard to the criminality of the tortured person, or the names of his accomplices, by the compulsion of suffering. Torture is divided as to intensity into the "question ordinary," a com-

paratively mild application of the instruments used in torturing, and the "question extraordinary," where these means were used to the greatest extent compatible with the preservation of life in the victim. The threats of torture were divided into "verbal territion," when the executioner described the torture, and "real territion," when the victim was placed upon the rack but not tortured. As to the time of its application, it was called the "question preparatory" when used for the purpose of compelling the accused to confess his own crime, and the "question *préalable* or preliminary" when applied to extort from a criminal the revelation of his accomplices. Torture seems to have been early practised as a means of discovering guilt, both judicially and privately, but was not inflicted on freemen or citizens till the time of the Roman emperors, except in cases of suspected crime against the state itself. The Greeks inflicted it on their slaves, and after their subjugation by the Romans it was inflicted on those who had not a claim to the name of Roman citizen; the oath of the citizen was considered sufficient. Under the emperors this distinction was not long continued, and men and women even of patrician birth were subjected to torture to compel confession of crimes existing only in the morbid imagination of tyrants. Wherever the code of Justinian was adopted as the basis of the legal system of European nations during the middle ages, judicial torture formed a feature of the examination of persons accused of crime; in the Teutonic nations it gradually took the place of ordeals and the trial by battle. In England it was probably never considered a part of the common law, though the *peine forte et dure*, which was used to compel a prisoner to plead to the indictment, had certainly some countenance from that law. (See *PEINE FORTE ET DURE*.) It was however recognized as one of the prerogatives of the crown to order it, and was thus in occasional use up to 1640, when the last case occurred. Severe and cruel as were the punishments inflicted by the ecclesiastical law, there is no evidence of a resort to "the question" by the inquisition or any other ecclesiastical court before 1252, when Innocent IV. called upon the civil arm to use it to induce confessions and accusations by offenders. Not long after this period the necessity of secrecy in the proceedings of the inquisition led to its extensive adoption, and to refinements of cruelty in its use before unknown. Judicial torture continued to be practised in most of the European states till the latter part of the last century. In 1780 the "question preparatory" was discontinued by a decree of Louis XVI., and in 1789 torture in general was abolished throughout the French dominions. In Russia it was abolished in 1801. In Austria, Prussia, and Saxony it was suspended soon after the middle of the last century, but in several of the smaller German states it continued on the statute books till the present century. Beccaria, Tho-

masius, Hommel, Voltaire, and Howard were instrumental in bringing about its discontinuance. In the United States torture has never been reckoned an adjunct of judicial examination, though there are traces of the belief in its necessity among the lower classes in some of the early colonial enactments.—The instruments of torture have varied at different periods and in different countries. Among the Romans, the scourge was the usual instrument; the *equuleus*, a sort of upright rack, was an invention of the Romans used upon their slaves, to which pincers to tear the flesh, fire, &c., were added. The rack as used in the tower of London was of uncertain origin; it consisted of an open frame of oak under which the prisoner was laid on his back, and his wrists and ankles fastened by ropes to rollers at the end of the frame, which were tightened by means of a ratchet wheel till the whole body was brought to a level with the top of the rollers, and in the "question extraordinary" till the joints were dislocated. The "boot" was the favorite French instrument of torture; in this rings of iron were passed around the legs, and wooden wedges driven between them and the flesh till the muscles were reduced to jelly. Among other instruments used to test the power of human endurance were the thumbscrew; iron gauntlets; the "little ease," a narrow cell in which the prisoner was confined for several days, and in which the only position possible was one which soon cramped every muscle; the "scavenger's daughter" (a corruption of "Skevington's daughter"), an instrument invented by Sir William Skevington, which so compressed the body as to start the blood from the nostrils, and often also from the hands and feet; the torture by water; and numerous other inventions capable of producing intense suffering.—Though, as before remarked, not properly reckoned as tortures, some notice should here be taken of those forms of punishment which aimed at making the penalties of crime terrible by the intensity of the physical suffering they inflicted. Ingenuity seemingly exhausted its powers in the invention of modes of inflicting agony upon the offender against the laws. Crucifixion, fastening to the cross with cords, and anointing the body with honey that insects might torment the helpless victim, hanging up in a cage, suspending the culprit by the arms while weights were tied to the feet, the fastening of limbs to trees which were forced into proximity to each other and then suffered to fly apart, pouring melted lead into the ears, immersing one or more limbs or the whole body in boiling oil, suspending over a slow fire, plucking out the hair in masses, slitting the nostrils and lips, putting out the eyes, cropping, cutting off the hands, branding, mutilation, crushing the body with heavy weights, starvation, deprivation of air, confinement in *oubliettes* or bottle-like prisons without ventilation, pulling out the nails, and breaking on the wheel, were a few of the many means by

which punishment was inflicted, often for offences of a secondary grade, within the past 200 years. To the same humane writers who effected the discontinuance of torture, is due in a great degree also the abolition of these cruel punishments.—See Jardine, "On the Use of Torture in the Criminal Law of England" (8vo., London, 1839); MacLaurin, "Introduction to Criminal Trials;" Auguste Nicolas, *Si la torture est un moyen sûr à vérifier les crimes secrets* (12mo., 1682); Reitemaier, *Sur la question chez les Grecs et les Romains*; and Mittermaier, *Das Deutsche Strafverfahren*, vol. i.

TORY, a term used to designate one of the principal political parties of Great Britain. It first occurs in English history in 1679, during the struggle in parliament occasioned by the introduction of the bill for the exclusion of the duke of York from the line of succession, and was applied by the advocates of the bill, the whigs of that day, to its opponents, as a title of obloquy or contempt. "The exclusioners," says Roger North, "observing that the duke favored Irishmen, all his friends, or those accounted such, by appearing against the exclusion, were straight become Irish, and in the copia of the factious language the word tory was entertained, which signified the most despicable savages among the wild Irish; and being a vocal, clear-sounding word, readily pronounced, it kept its hold, and took possession of the foul mouths of the faction, and everywhere as these men passed we could observe them breathe little else but tory." ("Examen," p. 321.) Hence Dr. Johnson says that the word tory is "a cant term, derived, I suppose, from an Irish word signifying a savage." In the opinion of some authors the tories were originally merely the successors of the cavaliers of the civil wars, men who believed that the maintenance of a royal line was the end or the necessary means of a lawful government; who vindicated the divine right of kings, and held high notions of prerogative; in other words, the court party in contradistinction to the country party. However accurate this definition of the party may have been at the time the name was first applied to it, the tories subsequently took a broader ground, and their leading principle became the maintenance of things as they have been, or at least as they are; whence Johnson gives the following definition: "One who adheres to the ancient constitution of the state and the apostolical hierarchy of the church of England." Except during the administration of Oxford and Bolingbroke (1710-'14), the tories did not come into power until near the middle of the 18th century; but from that time until the agitation of the reform bill in parliament they held almost uninterrupted ascendancy. Since 1830 their influence has been less predominant. The word tory, however, has for several years ceased to designate an existing party, but is rather applied to certain traditional maxims of public policy; and the political successors of

the tories are now commonly known as conservatives, a term originally assumed in contradistinction to destructive, by which name the radical reformers were sometimes designated.—In the American war of independence the adherents to the crown were called tories; but after the termination of that contest the name dropped out of use in American politics.

TOTILA (properly BADUILA), a Gothic king of Italy, died A. D. 552. He was duke of Friuli, served efficiently against the Greeks, and was chosen king in 541, upon the surrender of Vitiges at Ravenna. When Belisarius was withdrawn from the service against the Goths, Totila overran the greater part of Italy, and in 546 entered Rome by the treachery of some Isaurian sentries. Very few of the citizens were killed by the soldiers, and Totila held peaceful possession of the city until compelled to leave it in order to repair the reverses his armies had sustained in Lucania. In his absence Rome was recovered by Belisarius, and in 547 Totila was repulsed in the endeavor to retake it. In 548 Belisarius was again recalled to Constantinople, and Rome once more fell into the hands of Totila. In 552 Narses was sent into Italy by the emperor Justinian, and Totila advanced against him. A battle was fought at Tagina in Umbria, in which the forces of Totila were completely defeated, and he himself mortally wounded.

TOTLEBEN. See TODLEBEN.

TOTT, FRANÇOIS, baron de, a French adventurer, born in La Ferté-sous-Jouarre, Aug. 17, 1738, died in Tatzmanskorf, Hungary, in 1798. He was the son of a Hungarian exile, early entered the army, and in 1755 went to Constantinople as attaché to the French embassy. In 1763 he returned to France, and a few years afterward was made consul in the Crimea by the duke de Choiseul; but he became so involved in intrigues that in 1769 he was removed. Repairing to Constantinople, he entered the sultan's service, and continued in it until 1776, during which time, according to his own account, he had a great share in directing the military operations of Turkey. After his resignation he was sent by the French government to inspect the consular establishments of the Mediterranean ports from the archipelago to the Barbary states. Returning, he retired to private life, and prepared an account of his observations for 20 years, entitled *Mémoires sur les Turcs et les Tartares* (1784), which was translated into several languages, and long retained its popularity. In 1781 De Tott was made major-general, and afterward governor of Douai. This last position he held until 1790, when he was nearly murdered by the garrison, to whose republican principles he had opposed himself. He fled to Switzerland, then to Vienna, and died in obscurity.

TOTTEN, GEORGE MURKIN, an American engineer, born in New Haven, Conn., May 28, 1809. He commenced his career as a civil engineer at 18 years of age, and until 1844 was employed upon railroads and canals in Massa-

ehusetta, Connecticut, Pennsylvania, New Jersey, Virginia, and North Carolina. He was next engaged for 5 years upon the survey and construction of the *Canal del Dique* in New Granada, and in 1849 was appointed engineer-in-chief of the Panama railroad, which in 1855 he brought to a successful completion. He has since been occupied with various engineering enterprises in the United States.

TOTTEN, JOSEPH GLAZIER, an American officer of engineers, born in New Haven, Conn., in 1788. He was graduated at the military academy at West Point in June, 1805, and immediately appointed a 2d lieutenant of engineers. At the commencement of the war of 1812 he held the rank of captain, and for his services as chief engineer during the campaigns of 1813 and 1814, under Generals Dearborn and Maccomb, he was brevetted successively major and lieutenant-colonel. In Sept. 1824, he was brevetted colonel for 10 years' faithful service. In 1838, having attained the intermediate grades, he was appointed colonel and chief engineer, and at the same time inspector of the military academy. He accompanied the army under Gen. Scott to Mexico in 1847 as chief engineer, and for "gallant and meritorious conduct at the siege of Vera Cruz" was in the same year brevetted a brigadier-general. In 1851 he prepared for the use of the war department a "Report on the subject of National Defences."

TOUCAN, a name given to the scansorial birds of the family *ramphastida*, derived from the Brazilian imitation of their note. The family is remarkable for the disproportionate size of the bill, which however is very light on account of its spongy texture; it is strengthened internally by a network of thin bony laminae, freely supplied with vessels and nerves; it is broad at the base, without a cere, smooth, with the culmen curved, sides compressed, tip hooked, and the sides serrated; the tongue is long and slender, provided with numerous barbs on each side directed forward; the bill is usually adorned with bright colors which fade after death; the tarsi covered with transverse scutes, the quills almost concealed under the large coverts, the tail with 10 feathers; claws curved and sharp; toes 2 before and 2 behind; orbital region naked; furcula of 2 bony pieces, thin and not united below, and sternum with 2 deep incisions on each side behind. They are peculiar to tropical South America, living in flocks in the forests, where they make a great chattering as they hop from branch to branch in search of food; they feed principally on pulpy fruits, also on fish, eggs, larvae, and small birds and reptiles; they are said to toss their food into the air, and to catch it in the open bill, swallowing it at once, though this is denied by Edwards. When roosting they throw their tail upward and forward, and rest the enormous bill on the back, giving them a lazy and grave look, which has caused the negroes to call them preachers. They are generally hand-

some birds, representing in America the hornbills of Asia and Africa; they are not powerful fliers, and are strictly arboreal, not climbing like the woodpeckers, but hopping among the branches with such grace and agility as to have suggested for one of them the specific name of Ariel. The nest is made in holes in trees, and the eggs are 2, rounded and white. They are strong and shy, posting a sentinel while they feed, whose warning cry resembles the word *tucano*; the skin is bluish, and the flesh eatable though rather tough; they sometimes commit great havoc with fruit, and are often killed for food and for their brilliant feathers; they are very sensitive to cold.—In the toucans proper (*ramphastos*, Linn.) the bill is higher and wider than the forehead, looking as if too large for the head and belonging to another bird; the nostrils are hidden behind the prominent base; wings short and rounded, with the first 4 quills graduated and narrowed at the tip, and the 5th the longest; tail short and nearly even; feet short and stout; the colors are generally black with patches of white, red, and yellow, especially under the chin. The toco toucan (*R. toco*, Gmel.) is 17 inches long, of which the bill is more than a half; plumage black with throat and rump white, vent red, bill orange red with black tip; it inhabits Guiana and Brazil, where it is often shot for its destructiveness. The yellow-breasted toucan (*R. tucanus*, Linn.) has a yellow throat, with red vent and breast spot, and the rest of the plumage black. There are more than a dozen other species.—In the genus *pteroglossus* (Illig.), generally called aracaris, the bill is much smaller and sometimes not out of proportion to the head, as high as the forehead, with the nostrils conspicuous at the base; 4th, 5th, and 6th quills longest; tail long and graduated; the colors are usually green, with red or yellow on the breast. There are more than 30 species, with habits similar to those of the last genus. The aracari toucan (*P. aracari*, Illig.) is 17 inches long, with a bill of 4 inches; plumage blackish green, with yellowish abdomen, red median abdominal bar and rump; upper mandible with a longitudinal black stripe. The many-banded toucan (*P. pluricinctus*, Gould) is 20 inches long, green with a scarlet rump, and the breast yellow with 2 black bands; it is found on the upper Amazon.—For descriptions and figures of this family, see Gould's "Monograph of the Ramphastidae" (fol., London, 1884).

TOUCH, the modification of the common sensibility of the body, especially seated in the skin, whose adaptation for the purpose has been alluded to under that title. It is the sense through which we take cognizance of the palpable properties of bodies, and requires actual contact of the exciting substance with the skin, except in the sensations of heat and cold; by it we obtain an idea of resistance or weight, temperature, size, shape, smoothness or roughness, &c., assisted by the muscular sense; alone and of itself imperfect, it affords most impor-

tant information concerning the external world by correcting many fallacies derived from the unaided sense of sight. It is most acute at the tips of the fingers, on the tongue, lips, portions of the mucous membrane, and on the nipples, where the sensory papillæ are the most numerous, each one receiving one or more nerve fibres. The papillæ are elevations of the surface of the cutis, averaging $\frac{1}{16}$ of an inch in height, and $\frac{1}{32}$ in diameter at the base; on the palms they are arranged in rows, as many, according to Weber, as 81 compound and 150 to 300 simple ones in the area of a square line; they are always covered by the epidermis or cuticle, to which they closely adhere, and which is thickest in the intervals of the rows; if the epidermis be removed, there is great sensitiveness to pain with the loss of tactile power; if it be too thick, as on the heel, touch is almost null. The nerve fibres appear to terminate in what has been called the axile body in the interior of the papilla, which, according to Wagner, its discoverer, is an organ *sui generis*. Kölliker considers it analogous to the bundles of fibrous tissue encircled by elastic fibres found in the substance of the cutis, and Huxley as a continuation and increased development of the neurilemma of the nerve tube and as analogous to the Pacinian bodies; these organs are found only in the papillæ of the most sensitive parts, and are therefore not essential to touch, serving rather to intensify tactile impressions where delicacy of this sense is required. The optic thalami at the base of the brain are considered by Carpenter as the ganglionic centres of the nerves of common sensation, which ascend to them from the spinal cord and the medulla oblongata; they are connected by the soft and posterior commissures; in like manner the striated bodies are connected with the anterior tract of the spinal cord, and from them issue the motor impulses in answer to the sensations excited through the former. All the afferent nerves, except those of special sense, apparently minister to the sense of touch, by virtue of their connection with the seat of common sensation in the brain; those of the lower extremities are less concerned in conveying sensations than those of the upper, though they are far more efficient in producing reflex movements, probably because they have more fibres whose centre is in the ganglionic substance of the spinal cord, and fewer which pass up to the brain. —The mind must be directed to sensations for them to be perceived; a sensation hardly at all painful to an inattentive or otherwise busily employed person, may become intolerable if the attention be directed to it. The mucous membranes differ remarkably from the skin in their inflammatory states not being accompanied by increased sensibility; a fortunate provision, as otherwise the simplest functions of respiration, digestion, nutrition, and excretion could not be performed without great pain under comparatively trifling morbid conditions. The acuteness of touch differs in various parts

of the body, generally in proportion to the vascularity of the part; the non-vascular parts, like the hair, nails, and teeth, have no sense of touch, while on the skin the nerves are spread in a minute network. Its relative acuteness has been measured by Weber, by placing the legs of a pair of compasses on the skin, and approximating them until brought within the smallest distance at which they could be felt as distinct points, and with the following results: the point of the tongue, $\frac{1}{4}$ a line; palmar surface of 8d finger, 1 line; red surface of lips, 2 lines; tip of nose, 8 lines; edge of dorsum of tongue, 4 lines; skin of cheek, palm of hand, and end of great toe, 5 lines; back of hand, 8 to 14 lines; back of foot, 18 lines; over spine, and in middle of arm and thigh, 80 lines. There are considerable variations in this respect in different individuals. There are many modifications of the sense of touch, one of the principal of which has been noticed under TASTE. The feeling of tickling is most easily excited in parts having a feeble sense of touch, as the arm pits, sides below the ribs, palms, and soles, while the sensitive points of the fingers cannot thus be affected. This sense is exceedingly acute in the flying membrane of the bats and in the whiskers of the carnivora and rodents. It is combined with movement in that most wonderful instrument, the human hand, with its power of pronation and supination, opposability of the thumb, and great mobility of the fingers. As regards heat and cold, it is remarkable that the sensory nerves cannot distinguish between frozen mercury or the intense cold of solidified carbonic acid gas and red-hot iron; so that the story of the savage who dropped a piece of ice because it burned his fingers, has a good physiological foundation. Cold, by retarding the capillary circulation and by its direct sedative influence, deadens the sense of touch; in like manner, pressure upon or disease of the nerve trunks, and various states of the brain receiving the sensory impressions, are accompanied by obtuseness of touch; prominent among the causes acting on the nervous centres are the influence of toxic and anæsthetic agents, obstructed circulation, and chronic inflammations; on the other hand, irritation and acute inflammation in the course of the nerves, at their peripheral terminations, or in the centres, may be accompanied by hyperæsthesia or excessive sensitiveness of the surface. Subjective sensations, or those dependent on internal causes, are very common in the sense of touch; those of pleasure and pain, heat and cold, itching and creeping sensations, &c., are familiar examples, and are especially the prerogatives of nervous persons. Touch may be greatly improved when the other senses are impaired or lost, partly from the greater attention given to the sensations, and partly from an increased development of the tactile organs from more frequent use; instances of the education of this sense are very remarkable and well known in the blind, who

by their delicate touch have been enabled to read from raised letters, and to become eminent mathematicians, musicians, mechanics, naturalists, and sculptors; the fingers may even perform the work of eyes to the degree of distinguishing colors, by perceiving the differences in surfaces which reflect one colored ray and absorb the rest. It is, in the lower animals, most acute in the hands, feet, and prehensile tail of monkeys; in the lips and tongue of herbivora; in the snout of the elephant, pig, tapir, and mole; in the flying membrane, ears, and nasal appendages of bats, which can perceive even the vibrations of air; in birds, in the under surface of the toes and their webs, and in the sensitive skin of the mandibles of the duck tribe and some waders; in the under surface of the toes in many lizards, in the extensible tongue of the chameleon and serpents, in the naked skin of batrachians, and in the thumbs of the males of the latter during the reproductive season; in the antennae and palpi of arthropods, in the oral appendages of mollusks, and in the tentacles of radiates.

TOULMIN, CAMILLA. See CROSLAND.

TOULMIN, JOSHUA, D.D., an English clergyman, born in London, May 11, 1740, died in Birmingham, July 23, 1815. He was educated at St. Paul's school, and at the so called dissenting academy in the house of Dr. Samuel Morton Savage, and, after being licensed to preach, became pastor of a dissenting congregation in Colyton, and in 1766 of a Baptist congregation in Taunton, where he also conducted the business of a bookseller. He subsequently adopted Unitarian opinions, declined invitations to Unitarian pastorates in Gloucester and Yarmouth, received the degree of D.D. from Harvard college in 1794, and in 1804 was chosen one of the ministers of the Unitarian congregation at Birmingham, formerly presided over by Dr. Priestley, in which position he remained till his death. His principal publications were: "Memoirs of Socinus" (1777); "Letter to Dr. John Sturges on the Church Establishment" (1782); "Dissertations on the Internal Evidences of Christianity" (1785); "Review of the Life, Character, and Writings of John Biddle, M.A." (1789); an edition of Neal's "History of the Puritans," with notes and additions (5 vols., 1794-'7; reprinted, 3 vols., 1837); "Biographical Tribute to the Memory of Dr. Priestley" (1804); "Memoirs of the Rev. Samuel Bourne" (1809); and a "Historical View of the State of the Protestant Dissenters in England" (1814). He also published several volumes of sermons, and contributed to the "Theological Repository," "Monthly Magazine," and other periodicals.

TOULON, a maritime city of France, department of Var, situated at the head of a double bay of the Mediterranean, in lat. 48° 7' N., long. 5° 56' E., 80 m. S. E. from Marseilles, and 525 m. S. S. E. from Paris; pop. by the census of 1862, 84,987. Toulon stands upon ground which rises gradually from the

sea, and is sheltered by a ridge of lofty mountains, extending round the bay. A tongue of land stretches nearly across the entrance of the bay, and, together with all the adjacent points, is strongly fortified. The town, in addition to ramparts, bastions, and ditches, has numerous forts and outworks upon the surrounding heights, and is entered by two gates. The streets are narrow and irregular, and the squares, with the exception of the *Placed'Armes*, are all small. Toulon is the second naval port of France, and has 8 great arsenals, a school of naval medicine and one of naval artillery, and various other institutions connected with the navy and with commerce, beside a college, botanical garden, observatory, &c. There are two harbors, separated from the inner road and from each other by piers. One of them is surrounded by good houses and quays, and is used for mercantile purposes; while the other is surrounded by extensive government buildings, which consist of several covered slips for building vessels, workshops of different kinds, and large storehouses containing supplies for the navy; 3,000 workmen are here employed. In the armories there is a fine collection of ancient arms, and numerous valuable models of vessels of various descriptions. The naval school has a good library attached, and there are prisons to accommodate about 5,000 convicts. There are manufactories of woollen goods, imitation morocco leather, soap, &c. Ship building is carried on, and there are several foundries.—Toulon was known as a harbor in the time of the Romans. During the middle ages it was several times taken and sacked by the Saracens. In the reign of Louis XII. a tower was begun, which Francis I. completed, to defend the town from the Barbary pirates. Henry IV. strengthened the fortifications, and Louis XIV. established a royal dockyard and expended large sums under the direction of Vauban in fortifying the town and improving the accommodation of the harbor. In 1707 the combined English and Dutch fleets made an unsuccessful attack upon it by sea, while the duke of Savoy attempted to take it by land. In 1798 the royalists surrendered Toulon to the British; and during the siege which ensued Bonaparte gave the first remarkable proofs of his great military talents. When the British were obliged to evacuate the place, they burned all the maritime establishments and the greater part of the French men-of-war. The republicans gave it up to general pillage and massacre in revenge for the inhabitants having admitted the British. They also took from it its rank of capital of the department, which has never been restored. Napoleon III. has enlarged the fortifications and almost doubled the extent of the city.

TOULOUSE (anc. *Tolosa*), a town of France, capital of the department of Haute-Garonne, situated on the Garonne at the junction of the canals du Midi and Brienne, and on the railroad from Bordeaux to Cetta, 182 m. S. E. from Bordeaux and 200 m. N. W. from Marseilles;

pop. in 1862, permanent and floating, 118,229. The town is principally built upon the right bank, but part of it stands upon an island in the river, and the suburb of St. Cyprien occupies the left bank. The walls formerly surrounding it have been nearly all removed to make room for improvements. The streets are narrow and crooked, badly paved, and dirty. Considerable alterations, however, have lately been made, and the town is assuming a better appearance. Among the improvements may be mentioned the Place du Capitole and the Place Lafayette. The former consists of an extensive wall built square, ornamented with fountains, with one side occupied by the *hôtel de ville*, and is the principal place of business; and the latter is circular, lined with handsome mansions, and on the E. side opens into a fine promenade. The cathedral was commenced early in the 13th century, but has been since extensively repaired and altered, and now presents a very irregular appearance. There are several other churches, the most remarkable of which is the old church of St. Sernin, in the Romanesque style. Toulouse has an artillery school, several societies for advancing knowledge, a university academy, a medical and many other schools, a public library, an observatory, a botanical garden, a museum, and a picture gallery. The houses are nearly all built of red brick, and are only remarkable for their clumsy and gloomy appearance. The river is navigable, and is crossed by a bridge 810 feet long and 72 feet broad. There are powder mills, a cannon foundry, and an arsenal. The manufactures consist chiefly of coarse woollen and cotton goods, starch, outlery and hardware, earthenware, vermicelli, wax candles, and leather. *Pâtés de foie de canards*, or duck-liver pies, are made in great numbers and sent to other parts of France. An extensive trade is carried on, which is greatly facilitated by the water communication with both the Mediterranean and Atlantic. Toulouse is the see of an archbishop, and the seat of the court of appeals for several departments.—It is a place of great antiquity; but though the Romans ornamented it with many public buildings, no remains of any of them are now visible. The Visigoths captured it early in the 5th century, and made it the capital of their kingdom, which it continued to be for about 100 years. In 631 it became the capital of the Visigothic kingdom of Aquitaine, and it was ruled by independent counts from 778 to 1271, when it was united to the crown of France, after which it was the capital of Languedoc till the revolution. Its university and school of medicine were formerly very celebrated. The most remarkable event which has occurred at Toulouse in modern times was the battle fought in its immediate vicinity, April 10, 1814, between the British under Wellington and the French under Soult, in which the latter were defeated. Though Bonaparte had abdicated at the time, both generals were ignorant that hostilities had ceased.

TOURAINE, formerly a central province of France, now forming the greater part of the department of Indre-et-Loire, bounded by the provinces of Maine, Orléanaise, Berry, Poitou, and Anjou. It was divided into Upper and Lower Touraine. The capital was Tours. The Loire formed the dividing line between the two parts of the province, and the Cher, the Vienne, the Creuse, the Cluise, and the Indre also drained it. In the time of Julius Cæsar Touraine was inhabited by a peaceful and somewhat indolent people, the Turones, who submitted to the Romans after some opposition. In the 5th century they were successively attacked by the Huns and the Visigoths, in 480 became subject to the Gothic king Euric, and in 507 to Clovis, king of the Franks; and after the death of Dagobert I. it became a part of the kingdom of Neustria, and later of the empire of Charlemagne. From 941 to 1004 it was an independent province ruled by Thibaut, count of Tours, and his son and grandson, and subsequently to that period was embraced in the more extended district, comprising also Champagne and Brie, over which the counts of Tours ruled. In 1045 the count of Anjou, having captured Thibaut III., compelled him to give Touraine for his ransom. In 1208 it was taken by Philip Augustus from King John of England and annexed to the French crown. It was erected into a duchy in 1360 by John the Good, which was held at one period by the earls of Douglas and Mary, queen of Scots. Francis, duke of Alençon (died 1584), was the last who held it as an apanage. Its delightful climate has made it always a favorite resort, and its soil has been the scene of numerous important battles and historical events. In the 16th century it was the battle ground between the Protestants and Catholics; and, a large proportion of its inhabitants being Protestants, the revocation of the edict of Nantes nearly ruined it.

TOURMALINE, a mineral composed of silicates of alumina, the earths, and iron, with from 5 to nearly 12 per cent. of boracic acid. It crystallizes in the hexagonal system, the two extremities of the prism being usually unlike. Hardness 7 to 7.5, or between quartz and topaz; specific gravity 2.94 to 8.3. It is found black (schorl), brown, blue (indicolite), green, red (rubellite), and rarely white or colorless (achroïte). Sometimes the crystals are red at one extremity and green at the other, or red internally and green externally, or *vice versa*. Such specimens are found at Paria, Me., Chesterfield, Mass., and in Siberia, and these are also the best localities for rubellites and green tourmalines. The white come from St. Gothard, Siberia, and Elba. Black tourmalines and common varieties of the other colors occur in many parts of Europe and America, and the black is sometimes in such abundance as to form a large part of a rock called "schorl rock." Tourmaline becomes electrified by heat or friction with great readiness, and it has been sup-

posed that the ancients were acquainted with this property. A slice cut from a tourmaline parallel to its axis forms a perfect analyzer for polarized light (see POLARIZATION OF LIGHT), and this is its most valuable application. Tourmalines are seldom used in jewelry, though fine rubellites form beautiful gems and bear a high price. In the grand duke's collection at Florence there was a specimen 11 inches square, with 4 erect and one prostrate green tourmalines, 4, 2, and 2½ inches long, and ¼ to 1 inch thick. In the British museum is a magnificent group of pink tourmalines nearly a foot square, given by the king of Burmah to Col. Sykes, while commissioner at his court. The tourmaline appears to have been first brought to Europe from Ceylon by the Dutch, about the end of the 17th century, and was exhibited as a curiosity, on account of its first attracting and then repelling light bodies when electrified by heating it. It was then considered as a sort of magnet, but appears to have been little known even down to the middle of the 18th century, as Linnaeus, who was the first to refer its attractive power to electricity, had never seen one. In 1740 a specimen was worth 8 or 10 Dutch florins, or \$3.28 to \$4.10.

TOURNAMENT (It. *torneo*; Fr. *tourner*, to turn), a military sport of the middle ages, in which the parties engaged exhibited their courage, prowess, and skill in arms. It took its rise after the establishment of the feudal system, and appears to have been introduced into northern Europe as early as the middle of the 9th century, although several centuries elapsed before it came into familiar or reputable use. This was owing perhaps to the costliness as well as the sanguinary character of the contests in the early tournaments, which often resulted in the death or serious injury of several of the combatants, and were conducted very much in the spirit of the gladiatorial shows of the ancient Romans. Hence the prohibition of the practice by such princes as Henry II. of England, and the steady opposition of the church from the middle of the 12th to the middle of the 18th century. With the institution of chivalry and knighthood the tournament lost many of its objectionable features; and as an incentive to martial exploits and to a generous emulation in all knightly offices, it began during the period of the crusades to be tolerated and even encouraged throughout Christendom. The church, which had prohibited persons from engaging in tournaments on pain of excommunication, and had denied Christian burial to such as lost their lives in them, finally relaxed its opposition, and until the latter part of the 15th century the sport continued in full activity. It thenceforth became gradually transformed into a court pageant, often of the most magnificent and costly description; but the tragical death of Henry II. of France at a tournament in 1559 occasioned its abolition in all parts of Europe, although for nearly a century later it continued

to be occasionally revived at court festivities as a memento of the past rather than a subsisting and popular custom. The decay of chivalry, the introduction of firearms, and the gradual disuse of defensive armor, together with the rise of the commercial spirit and the new civilization thereby extended over the world, were the real causes of its decline. Whatever may have been the nature of the combats in tournaments at the origin of the practice, they soon became for the most part encounters between mounted adversaries (whence the derivation of the term, as illustrative of the agility required by the combatants in turning or managing their horses), who were knights or at least candidates for knighthood, as esquires or pages. A joust was, properly speaking, a combat between two knights, while the tournament included a number of jousts, or an encounter of several knights on a side.—In the course of time numerous regulations, having the authority of a code of laws, prescribed the manner in which tournaments should be conducted; and, except where national pride or rivalry, or personal enmity, inflamed the combatants, no serious result was likely to happen. They were generally held at the invitation of some prince upon the birth or nuptials of royal persons, during royal progresses, or at high court festivals, and heralds were sent into the neighboring kingdoms to invite the knights to be present. These, if the occasion was one of importance, came frequently from distant countries, attended by splendid retinues; and on the appointed day the galleries encircling the lists, or level enclosed space in which the knights contended, were gay with banners and costly draperies and crowded with spectators, conspicuous among whom were the ladies, whose approving smiles were the rewards most esteemed by the victors. In the flourishing period of tournaments two kinds of arms were employed, those expressly made for the purpose, consisting of lances with the points blunted, or covered with pieces of wood, called rockets, and swords blunted or rebated; and those ordinarily used in warfare, termed *armes à outrance*, which, however, in many cases were not permitted by the judges of the tournament. The blows, whether of lance or sword, were required to be directed at the head and breast, and no combatant was permitted to strike an adversary after he had raised his visor or to wound his horse. Each knight in attendance was obliged to prove his noble birth and rank, which were originally proclaimed by the heralds with sound of trumpet, whence the word *blazonry*, signifying the art of deciphering the heraldic devices on a coat of arms, from the German *blasen*, to blow. At a later period the emblazoned shields of the knights, suspended at the barriers or entrance of the lists, sufficed to indicate their rank and family. If upon the accusation of any lady present the bravery or loyalty of a knight was impeached, he was excluded by the heralds

from the contest. The heralds having proclaimed the laws of the tournament, at the sound of the trumpet the whole body of knights, each with his attendant squire, entered the lists in a glittering cavalcade, distinguishable only by their emblazoned shields or by the favors of their mistresses—a still prouder bearing—suspended from their crests, after which preliminary spectacle the martial exercises of the tournament commenced. At the word of the heralds, *Loincez-aller*, the opposing combatants rode at each other in full career, striving to direct their lances fairly upon the helmet or shield of their adversaries, that one being adjudged the victor who broke most spears “as they ought to be broken,” who held his seat the longest, and who showed most endurance in keeping his visor closed. Sometimes dismounted knights encountered each other with swords or axes. The heralds and attendant minstrels meanwhile animated the combatants by appeals to their gallantry and devotion, or by approving shouts at any unusual display of strength or skill, the ladies waved their scarfs, and the friends of individual knights shouted encouragement from the galleries. At the close of these animating combats, the prizes were announced by the judges, selected from the older knights, but were awarded by female hands. “Victory in a tournament,” says Hallam, “was little less glorious, and perhaps at the moment more exquisitely felt, than in the field; since no battle could assemble such witnesses of valor. ‘Honor to the sons of the brave!’ resounded amid the din of martial music from the lips of the minstrels, as the conqueror advanced to receive the prize from his queen or his mistress; while the surrounding multitude acknowledged in his prowess of that day an augury of triumphs that might in more serious contests be blended with those of his country.”—A favorite form of the tournament was the so called passage of arms, in which a party of knights, assuming the office of challengers, offered combat to all who dared oppose them. Of this, as also of the *mêlée* or encounter of bodies of knights attended by their squires, a splendid description is given in Scott’s “Ivanhoe,” which affords a more vivid idea of the tournament, with all its martial exercises, than the writings of Froissart or any other of the old chroniclers. The later tournaments were however harmless in comparison with such sanguinary encounters as these; and the combatants, while aping the forms and usages of chivalry, were so destitute of the old knightly spirit of their predecessors in the lists as to content themselves chiefly with an ostentatious display of magnificent equipments or of skilful horsemanship. A splendid festival in the form of a tournament was given by the earl of Eglinton at Eglinton castle, in the west of Scotland, in 1839, on which occasion many of the visitors assumed the character of ancient knights, and a queen of beauty awarded the prizes.

TOURNAY, or TOURNAI (Flem. *Doornik*; anc. *Turris Nerviorum*, afterward *Turnarum*), a frontier town of Belgium, in the province of Hainault, situated on both banks of the Scheldt, 28 m. W. N. W. from Mons and 45 m. W. S. W. from Brussels; pop. 88,000. The river is crossed by several fine bridges and lined by spacious quays, planted with shade trees, and used as promenades. The town is strongly fortified and defended by a citadel constructed by Vauban. It is entered by 7 gates, and consists of the old town, on the left bank of the river, and the new town, on the right. The former contains the cathedral, which is a large and beautiful edifice in the Gothic style, of great antiquity, ornamented externally by fine towers with spires, and in the interior by several sculptures in marble, fine paintings by Rubens, and ancient remains; but it was considerably defaced during the French revolution. There are several other churches, the most remarkable being that of St. Brice, with the tomb of King Childeric adjoining. The market place, near the cathedral, contains a belfry supposed to have been part of a castle erected in the 13th century. Tournay is the seat of extensive manufactures, which give employment to about $\frac{1}{4}$ of the inhabitants; the more important products are woollen and cotton cloth, hosiery, linen fabrics, camlets, various kinds of yarn, waistcoat patterns and other fancy articles of dress, carpets, for which Tournay is particularly famous, earthenware and porcelain, bronze goods and hardware, cutlery, hats, paper, and leather. There are numerous breweries, and distilleries where curaçoa and other liqueurs are made, salt refineries, and dyeing establishments. Vessels of about 150 tons burden can ascend the river to Tournay, and it is connected by railroads with all the chief towns of Belgium and France.—At the time of its conquest by Julius Cæsar, Tournay was one of the chief towns of the Nervii. During the middle ages it was one of the most important towns of Belgium; and in modern times it has frequently been besieged and taken in the various wars that have desolated this part of Europe.

TOURNEFORT, JOSEPH PITTON DE, a French botanist, born at Aix, Provence, June 5, 1656, died in Paris, Nov. 28, 1708. He received a classical education, was destined for the church, and entered a theological seminary; but after his father’s death in 1677 he devoted himself to natural philosophy, in 1679 attended lectures in the medical school at Montpellier, afterward explored Languedoc, Roussillon, Catalonia, and the Pyrénées, and returning to Aix in 1681 began to classify the plants he had gathered. In 1688, being called to Paris by Fagon, physician of Louis XIV., he was appointed professor of botany in the *jardin des plantes*, and drew a large concourse to his lectures. In 1688 he visited Spain and Portugal, and a little later went to England and Holland, to gather plants. He was offered the professorship of

botany at the university of Leipsic, which he declined; became a member of the academy of sciences in 1692, and took the degree of M.D. in 1698, when already 43 years of age, publishing as his thesis the *Histoire des plantes qui naissent aux environs de Paris, avec leur usage en médecine*, which was reprinted with annotations by Jussieu (2 vols. 12mo., Paris, 1735). He had already published his *Éléments de botanique, ou méthode pour connaître les plantes* (8 vols. 8vo., Paris, 1694), which he translated into Latin under the title of *Institutiones Rei Herbariae* (8 vols. 4to., 1700), presenting a full exposition of his natural system of botany, several classifications of which have been preserved by Linnaeus. In 1700 under Louis XIV. he visited the island of Candia, the archipelago, Constantinople, the southern shore of the Black sea, Armenia, Georgia, and the interior of Asia Minor, gathering in this tour no fewer than 1,356 new plants. These were classified according to his system, and included many new species, described in his *Corollarium Institutionum Rei Herbariae* (1706). The general account of his journey, *Voyage du Levant*, which is considered a masterpiece in point of knowledge and interest, was printed at the expense of the government in 2 vols. 4to., the last being completed in 1717. It has been reprinted in 3 vols. 8vo.

TOURNIQUET (Fr. *tourner*, to turn), a surgical instrument for stopping the flow of blood in the limbs by exerting a strong compression on the principal artery. It was invented by Morel, a French surgeon, about the middle of the 17th century, and was modified subsequently by Nuck, Verduc, Monro, Petit, and Louis. Its usual form is that of a firm pad on the under surface of a brass plate, to which a strong band of webbing is attached, by means of which the limb can be ligatured, and a screw on the upper surface of the plate, which regulates at the same time the ligation and the pressure. So that the object desired, the compression of the artery, is attained, the form of the instrument is of but little consequence; a very effective tourniquet has often been extemporized by tying a knot in a handkerchief, and, having placed the knot over the artery, twisting the ends of the handkerchief with a stick. The tourniquet is of service in checking bleeding from a wounded artery in a limb, and for preventing its flow in amputation. It is also used, in some cases, to compress aneurismal and other tumors, with a view of producing coagulation or absorption; but at the present day other modes of compression are generally preferred for this purpose.

TOURO, JUDAH, an American philanthropist, of Jewish descent and faith, born in Newport, R. I., in 1776, died in New Orleans, Jan. 18, 1854. He removed to New Orleans in 1802, where he engaged in commercial enterprises, and also purchased much real estate. He accumulated a large fortune, and gave liberally through life to benevolent objects. In

1815 he served under Gen. Jackson in the defence of his adopted city, and was wounded in the battle. At his death he gave more than half of his property for charitable purposes. Among his bequests were \$80,000 to found an almshouse in New Orleans; \$65,000 to the 13 Hebrew congregations of that city; \$30,000 to the New York Jews' hospital; to the relief society for indigent Jews in Palestine, \$10,000, and for ameliorating the condition of the Jews in the Holy Land, \$50,000; to each of the Hebrew congregations in Boston, Hartford, New Haven, Newport, New York, Charleston, and Savannah, \$5,000; to the female asylum and boys' asylum in Boston, each \$5,000; and to the Massachusetts female hospital, \$10,000. At the period of his death he had no known living relatives.

TOURS (anc. *Caesarodunum*), a walled town of France, capital of the department of Indre-et-Loire, situated on a flat tongue of land between the Loire and its tributary the Cher, 120 m. S. S. W. from Paris; pop. in 1856, 33,204. The Loire is crossed by a handsome bridge of 15 arches. The town is of oblong form, and lies parallel to the river, the banks of which are lined by a fine quay with handsome houses and well planted promenades. A great number of the houses are modern, and several of the streets are well laid out, the principal one extending the whole length of the town, and having at one end a statue of Descartes, who was born in the vicinity. The cathedral of St. Gatien is 256 feet long and 85 feet wide in the interior, and is highly ornamented. The W. front is flanked by 2 domed towers 305 feet high, and has 3 lofty portals surmounted by a window of extraordinary dimensions. It contains, among other objects of great interest, a fine marble monument of the children of Charles VIII. and Anne of Brittany. There are several churches and ancient edifices. The church of St. Julian, built in the 13th century, now used as a coach house, is a fine pointed edifice; and 2 circular towers, enclosed within the cavalry barracks, formed part of the castle built here by Henry II. of England. The *hôtel de ville* contains a public library of 40,000 volumes and several remarkable MSS. The archiepiscopal palace is one of the finest buildings of the kind in France. There are several public walks, a race course, and a botanical garden. The most important manufacture is silk, which was established here earlier than in any other part of France by workmen brought from Italy in the 15th century. In the 16th century 20,000 hands were employed in this branch of industry, but the competition of Lyons, where the climate is more favorable to the silkworm, has reduced the number considerably. Broadcloth, rugs, woollen yarn, starch, leather, wax candles, and some wine and brandy are also manufactured.—Tours was anciently the capital of the Gallic tribe of the Turones, afterward of a division of Gaul under the Romans, and later of Touraine. It had a

population of 80,000 when the revocation of the edict of Nantes deprived it of nearly all its industry and almost all its inhabitants, and from this loss it has never recovered.

TOURVILLE, ANNE HILARION DE COUTENTIN, count de, a French naval officer, born at Tourville, arrondissement of Coutances, Normandy, in 1642, died in Paris, May 28, 1701. The son of a general in the army, he entered the order of Malta when only 14 years old, and early distinguished himself by bravery and talent in naval forays or *caravanes* against the pirates of northern Africa. So great was the fame of the young knight that the republic of Venice gave him a gold medal and chain, with the title of protector of maritime commerce; and on his return to France in 1667, Louis XIV. welcomed him at Versailles and gave him a captaincy with the command of a ship. In that capacity he participated in the expedition led by the duke of Beaufort against Candia in 1669; then served under D'Estrées in the war against Holland, and assisted in the battle of South Bay, June 7, 1672. In 1675 he was sent, with the chevalier de Valbelle, to support the inhabitants of Messina in their rebellion against Spain; and he greatly contributed, under Duquesne, to the victory of Agosta, April 22, 1676, in which the celebrated Dutch admiral De Ruyter was mortally wounded, and thus gained his promotion to the rank of chief of squadron or commodore. Off Palermo, May 31, 1677, by a timely attack, he nearly destroyed the combined fleets of Spain and Holland. In 1683 he shared in the attacks of Duquesne against Algiers; then in the bombardment of Genoa in 1683, and was made a lieutenant-general of marines. In 1688 he again bombarded Algiers, and was nominated "vice-admiral of the Levant." In the war against William III. of England, he united the Mediterranean fleet with that of Admiral Ohâteau-Regnault, and with him fought the English and Dutch fleets off Beachy Head, July 20, 1690, pursuing the former to the mouth of the Thames, where he destroyed 12 ships and many transports. In 1691, being appointed to the command of the ocean fleet, he annoyed the English, and, keeping the channel clear, favored the sending of French troops to Ireland in aid of James II. The next year, by positive order from Louis XIV., at the head of only 44 ships, he engaged off Cape La Hogue the English admiral Russell, whose forces were nearly double, and, after 12 hours of determined resistance, succeeded in escaping to port with the remains of his fleet. Promoted to a marshalship, March 27, 1693, he sailed from Brest, met off Cape St. Vincent the English and Dutch fleets conveying a large number of merchantmen bound to the Mediterranean, attacked them, and captured 27 vessels and destroyed 59, inflicting an immense loss on the enemy. On the peace of Ryswick in 1697, he retired to private life. His *Mémoires* (8 vols. 12mo., 1748-'58), by some unknown writer, are worthless.

TOUSSAINT, ANNA LUIZE GEERTRUIDE, a Dutch novelist, born in Alkmaar, Sept. 16, 1812. She first appeared as an author in 1827 with the romance of *Almagro*, which was succeeded by *De Graaf van Devonshire* (1838) and *De Engelse in Rom* (1840). These works met with success, and were followed by *Het Huis Lauverness* (3 vols., 1841), a historical romance of the time of the reformation, which gave her a European reputation. It was followed by her works on the life and fortunes of the earl of Leicester, entitled *Leycester en Nederland*, *De Vrouwen van het Leycester'sche Tijdperk*, and *Gideon Florens* (9 vols., 1851-'4). In 1845 her native village conferred upon her civil rights. In 1851 she married the painter Bosboom.

TOUSSAINT, FRANÇOIS DOMINIQUE, surnamed L'OUVREUR, a Haytian general, born near Cape St. François in 1743, died in the dungeon of St. Joux, France, April 27, 1803. His parents were both slaves, and of pure negro blood. His father was a native of Africa, and was said to be a son of a chief or king; he had been sold by the slave dealers to the count de Noé, upon whose estate of Breda he was employed. Upon this estate Toussaint was born, and during his youth was known as Toussaint Breda, and sometimes from his extreme slenderness as *Fatras Baton*, or "little lath." The director of the count de Noé's estate, M. Bayou de Libertas, was a mild and amiable man; and perceiving that Toussaint, who had been employed as a herdsman, was intelligent and faithful, he made him his coachman, and finally gave him a post of importance and trust in connection with the sugar manufactory of the estate. He had learned to read and write a little from a fellow slave, and on his promotion he endeavored to cultivate his mind by further study and reading. It is said that the abbé Raynal's "Political and Philosophical History of the European Colonies in the East and West Indies" fell into his hands, and that its pictures of the evil results of slavery had a powerful effect on him. It is certain, however, that he remained apparently contented with his lot till near his 50th year. When in 1791 the mulattoes, who had demanded a share in the representation and offices of the government from the whites, and had been maltreated and murdered by order of the colonial government, appealed to the negroes for help in enforcing their rights, though many of the blacks rose in insurrection and destroyed one third of the dwellings in the northern departments, Toussaint incurred the hostility of his race by remaining quiet and faithful. It was not until he had secured the escape of the director of the estate, M. Bayou, with his family and what personal property he could carry with him, that he united with the negro army. It was at that time commanded by 3 generals: Jean François, intelligent, but of no great courage or enterprise; Blassou, vindictive, fierce, and violent; and Jeannot, cowardly and cruel, who was soon after executed by his associates. Toussaint, at first

employed in a medical capacity, to which his knowledge of the medicinal properties of plants gave him some claim, was soon appointed brigadier-general; and though averse to cruelty, yet having more confidence in the military ability of Biassou than that of Jean François, he became a member of the staff of the former when the two quarrelled. The black leaders were naturally inclined to a monarchy, and when news came of the beheading of Louis XVI. they, and Toussaint with them, accepted the proffered aid of the king of Spain, and repelled the offers of republicanism of the French convention. He soon distinguished himself by the capture of the entire army of Brandicourt, the general of the whites, without bloodshed, and as a result of this capture took possession of Dondon, an important military post. He followed this on July 27, 1795, by the capture of Marmelade, another important post, the defeat of the French colonel Desfourneaux, and the seizure of Ennery and Gonaïves. The English now invaded the island and took Port au Prince, while the French, the Spaniards, the mulattoes, and the blacks were all contending with each other, in a purposeless but sanguinary strife. It was at this juncture that Toussaint, who was already in effect the commander-in-chief of the black forces, and who had entered upon the war with the sole purpose of securing the freedom of his race, became convinced that the only hope of obtaining that freedom lay in declaring for France, whose national legislature had, while making Hayti an integral part of France, proclaimed also the freedom of all the slaves. Spain, with which, prompted by his preferences for a monarchy, he had hitherto acted, evidently meant to perpetuate slavery; England had but a slight foothold in the island, and the mulattoes had no organization. If the power of France were once established, freedom and equality might prevail in Hayti. Deeming his duty to his race the one of highest obligation, he declared his fealty to France, and applied himself so energetically to bring all parties to the same conclusion that Laveaux, the French commander, exclaimed: *Mais cet homme fait ouverture partout*; and from this time he received his surname of "L'Ouverture" (the opening). He formed a junction with Laveaux, and, though the Spanish and English forces united against him, entered upon the campaign with such energy that he drove the English from nearly all their strong positions, took 28 Spanish batteries in 4 days, maintained a long line of defences against the allied enemy, who possessed twice his force, rescued Laveaux from the hands of Rigaud, the mulatto leader, who had imprisoned him, besieged St. Marc, where the English were in greatest force, 8 times, twice captured Mirebalais out of the hands of the allies, and finally closed the campaign by receiving the capitulation of the entire English force at St. Marc, and the abandonment of the effort by the Spanish to conquer the W. portion of the island. Appointed commander-

in-chief of St. Domingo in 1796 by Bonthonax, the French commissioner, Toussaint sought to restore order and industry to the island, and was successful, though opposed by Hédouville, the new commissioner, who, finding his own influence waning as that of Toussaint rose, fled to France to make complaint of the negro chieftain, who sent to the directory a statement of the true position of affairs. The French directory justified Toussaint and censured Hédouville. But the latter, on the eve of leaving Hayti, had purposely sown the seeds of discord between Rigaud, the jealous mulatto leader, and Toussaint, and had, by finally setting the former free from his obligations to the latter, prepared the foundations of a new civil war. Rigaud was able and daring, and for nearly the whole of the year 1799 the war between the blacks and the mixed race raged fiercely. The capture of Jacmel by Toussaint, after a long siege, was a severe blow to Rigaud; and subsequent successes of the black chief completely subdued the mulatto insurrection, and Rigaud with some of his officers fled to France. Roume, the French commissioner who had succeeded Hédouville, attempting to countenance the slave trade, and in other ways showing himself a traitor to Hayti and to France, Toussaint arrested and imprisoned him, and subsequently sent him to France, and took possession of the eastern end of the island, which had till then remained in allegiance to Spain. On Nov. 26, 1800, he assumed the government, amenable for his administration to the French directory alone; and in Jan. 1801, the whole island became subject to his sway. Understanding thoroughly the people whom he was to govern, he took measures to restore industry, to remove prejudices, and to establish good order. He invited the steward of his old master's estate and other well disposed white colonists back to the island, and soon agriculture was actively resumed and the laborers were busy in gathering their harvests. Whether from the love of display inherent in his race, or from his knowledge of its effect upon the blacks, he assumed great state in his public appearance, being richly attired and surrounded by a guard of 1,500 to 1,800 men, all in brilliant uniforms and admirably mounted. In private life, however, he was plain and temperate even to abstemiousness. At the very beginning of his administration Toussaint selected an administrative council of 9, of whom 8 were white proprietors and one a mulatto, all men of probity and intelligence. He also determined upon the adoption of a constitutional government; and in the constitution drawn up by the council, which was in most respects an admirable document, he was named president for life, and free trade was established. This constitution he sent with a letter to Bonaparte, then first consul, on July 16, 1801. It reached France at an unfortunate epoch. The peace of Amiens had closed the wars which had given employment to the armies of France, and

there was a large body of men among them ready to oppose the ambitious designs of the first consul, of whom it was necessary for him to rid himself. The freedom of the black race in Hayti lent him no renown, since it was accomplished without his aid, while its re-enslavement would gratify the colonists who were besieging the French court. The comparisons which were already drawn between the black and the white military hero, too, excited his animosity; and in the adoption of a constitution and the assumption of the office of president for life, without any previous suggestion from Bonaparte, the negro chieftain had unwittingly committed an unpardonable offence. Hence, when Vincent, the messenger of Toussaint, presented the constitution to the first consul, his instant reply was: "He is a revolted slave whom we must punish; the honor of France is outraged." An act was passed by the council and a decree issued by Bonaparte to restore the French colonies to their condition previous to 1789, that is, to the condition of slavery, and of course to put down Toussaint. In a subsequent decree St. Domingo or Hayti was excepted—an exception, as the event proved, intended to be only temporary. Gen. Leclerc, the husband of Pauline, Bonaparte's sister, was accordingly sent out with a force of 80,000 men, mostly veteran soldiers, and 66 war vessels. The expedition sailed in Nov. 1801, and arrived on the coast of Hayti in Jan. 1802. Among those in command in it were Rigaud, Pétion, and Boyer, all enemies of Toussaint. No declaration of war was made, but Leclerc attempted to enter Cape François with his force, and was opposed by Christophe, who was in command there, and who asked for a delay of two days, that he might consult with Toussaint. This was refused, and half an hour contemptuously allowed, when, rather than surrender, Christophe burned the city. Finding unexpected resistance at all points, Leclerc sent Toussaint's sons, who had been educated in France, and whom he had brought with him, hoping by their means to cajole the negro chief into submission, to their father, with a letter from Bonaparte and another from himself, couched in terms of mingled flattery and menace. The negotiation was ineffectual; though tenderly attached to his sons, Toussaint refused to sacrifice his country for them. Leclerc then declared him and his generals outlaws, and a sanguinary conflict ensued, in which one third of the French troops were killed or wounded; and though they possessed the seaports, yet the blacks from their mountain fastnesses were destroying them in detail. Finding that it was impossible to conquer the island in this way, Leclerc next sought to win over the negro generals. He began with Christophe, and by protestations that the freedom of the blacks was established, and that there was no object in the war, and by the lure of honors to be conferred on him in person, he succeeded in winning

him to his interest, and Dessalines and his other generals soon followed. He next made his propositions to Toussaint, offering as conditions of peace to respect the liberty of the people of St. Domingo, and confirming this by the most solemn oaths to leave the government of the island in Toussaint's hands, and to employ the officers of his army according to their rank, while for himself he would only hold the office of delegate from France by Toussaint's side. Toussaint, won by his apparent candor and liberality, accepted his offers to the people and army, but avowed his own determination to live in retirement. In the interview which followed, Toussaint upbraided Leclerc severely for the ruin he had brought upon Hayti, by his attacks upon him and his forces, without first seeking an interview. With affected humility, Leclerc acknowledged his fault, and was loud in his praises of the generalship and ability of the negro chief. Toussaint retired to his estate near Ennery, and endeavored amid arts of peace to banish from the minds of all around him the remembrance of the wars which had passed. But Leclerc, prompted by Bonaparte, had determined upon his destruction. Finding no occasion of reproach in his conduct, he had resort to deception to get him into his power, and at his direction Gen. Brunet on June 7 sent him an apparently cordial letter, asking for an interview of an hour in relation to some arrangements for providing for the black troops, inviting him to bring his wife with him, and closing with assuring him of the sincerity of his friendship. Suspecting no evil, Toussaint went as requested to Gonaïves, and after a short conversation Brunet left the room, when an armed force entered and seized him, and at midnight put him on board a French frigate. His family were also seized and sent on board the same vessel, and his house was plundered. They were at once sent to France, and on their passage Toussaint addressed two most touching letters to the first consul and the minister of marine, asking that his family might be protected. Arrived at Brest, an officer of police was sent, at 5 o'clock in the morning, to transfer him from the vessel. He was compelled to leave his family, which he was never allowed to see again, and permitted to take only his servant, who a few months later was also taken from him. On Aug. 17, 1802, he reached Paris under guard, and was at once confined in the Temple, from whence he was transferred, without trial, and without being allowed any interview with Bonaparte or his ministers, without even any explanation of the cause of his arrest, to the dungeons of the castle of Joux, in the department of Doubs. Here, deprived of all society, subjected to the intense cold with insufficient clothing, and his food reduced below what the physicians pronounced sufficient to sustain life, the heroic old man struggled against his fate, and appealed repeatedly but

in vain for a trial. The first consul sent his aid Caffarelli to demand where he had buried his money. Toussaint only replied: "I have lost something very different from money." Finding that his appeals for a trial produced no response, he commenced, as well as his failing strength would allow, his defence, which was transmitted to Bonaparte, but elicited no reply. His death by starvation was determined upon, and his pittance of food reduced; and finally the governor of the castle went away for 4 days and left Toussaint without food or drink. On his return he was dead, and the rats had gnawed his feet. An autopsy was held, and his death was said to have been caused by apoplexy. Several memoirs of Toussaint have been published. Among them are: *Histoire de l'expédition des Français à Saint Dominique*, by Metral (Paris, 1825); *Sur l'expédition des Français sous le consulat de Bonaparte*, by Isaac Toussaint L'Ouverture (Paris, 1825); *Histoire de l'île d'Hayti*, by Placide Justine (Paris, 1826); *Vie de Toussaint L'Ouverture*, by Saint-Rémy (Paris, 1850); "The Life of Toussaint L'Ouverture," by the Rev. John R. Beard, D.D. (London, 1853).

TOWN (Ang. Sax. *tan*, from *tinan*, to enclose), in Great Britain, an assemblage of houses, usually having a market, or a subdivision of a county. In early times the name was applied only to such collections of houses as were surrounded by a wall. Sir Edward Coke says that a place cannot be a *vill* (or town) unless it hath, or in times past hath had, a church and celebration of divine service, sacraments, and burials. Sir John Holt says that a *vill* or town must have a constable, and that otherwise it is only a hamlet, an assemblage of houses having no specific legal character. In England, however large a town may be, it cannot become a city unless it is or has been the see of a bishop, and has a cathedral; thus Birmingham, with nearly 300,000 inhabitants, is only a town, while Lichfield, with fewer than 7,000, is a city.—In New England, from its first settlement, the town was the primary organization, and seems to have been based on the old Saxon idea of a tithing. The colonists had no sooner formed a settlement, and erected their cabins in convenient proximity to each other, than they organized themselves into a town, an independent municipality, in which every citizen had a voice and vote. The territory claimed by these towns might be large or small, but each was an independent and self-governing democracy, and the voters were equal in the town meeting. In some of these towns there were restrictions on the admission to citizenship; thus in New Haven, or Quinnipiack, and the towns which afterward affiliated with it, no man could vote in town meeting who was not a member of the church; and in the towns of the Massachusetts colony, as in most of the others, the possession of a certain amount of property was necessary to the exercise of the right of suffrage. The citizens in town meeting

assembled had the control of all matters relative to civil and criminal jurisdiction in the town; its finances, roads and bridges, support of its poor, and with some exceptions its public schools, were ordered and maintained by the town. The representatives of the town authority in all these matters, except the school supervision, were the selectmen, 3, 5, 7, or 9 in number, whose chairman, usually called the first selectman, was the executive officer of the town. In the colonial governments, and to a considerable extent under the state governments, the town was the primary assembly of the state. In the New England colonies the towns were combined in counties long after their establishment and representation as towns, so that the county there was a collection of towns, rather than the town a subdivision of the county. This system of town organizations is maintained throughout New England to the present day. The management of their local affairs, the support of the poor, the police regulations, the control of the schools, and the maintenance of roads and bridges, are all within the scope of the town authorities; and in all the New England states except Massachusetts and Maine, in which the district system has been adopted within 30 years, every town is represented in the lower house of the legislature. Mr. Palfrey, in his "History of New England," says that "with something of the same propriety with which the nation may be said to be a confederacy of republics called states, each New England state may be described as a confederacy of minor republics called towns."—In the other colonies, and the states formed since the revolution, the town organization has not been so prominent. The *wycks* of the early Dutch administration, and the townships of later times, in the colony of New York, were mostly the properties of great landed proprietors, occupied by a kind of feudal tenure by their tenants; and when, after the organization of a state government, the lands were sold to actual settlers, the county organization generally, and perhaps always preceded that of the town. Occasionally borough or municipal charters were granted by the state legislature, conferring upon certain small districts of territory powers nearly analogous to those of a New England town; but except in these it had no representative in New York or most of the middle or western states. Recently the control of the public schools has been conferred upon the townships, and in the new states the gift of a section of land for school purposes to each township has thrown upon the town authorities some duties which do not appertain to them in some of the older states. All of the newer states of the West and North-West are surveyed in townships, usually of 36 miles square; but this survey carries with it no local political authority. In the southern states there are no townships. The county organization is the one which governs local matters, except in cities or boroughs spe-

cially chartered. A town there is simply a collection of dwellings of greater or less size, and in a majority of cases there is but one in a county (and not always even one), which has gathered around the site of the county buildings.—The towns of antiquity were usually colonies from some enterprising and commercial state, which by purchase or conquest, more frequently the latter, had obtained foothold upon a territory, and there established themselves in the pursuit of agriculture, commerce, or the arts. They frequently held sway over a considerable adjacent territory, and were sometimes independent, oftener tributary to some great power, and sometimes ruled by a governor, prætor, or proconsul of Rome or other dominant empire. In the middle ages there sprang up a considerable number of free or independent cities and towns on the continent of Europe, which often allied themselves together for mutual protection. (See HANSEATIC LEAGUE.)

TOWNE, a new N. E. co. of Georgia, bordering on North Carolina, and drained by the head streams of the Hiwassee river; area, about 250 sq. m.; pop. in 1860, 2,459, of whom 108 were slaves. The surface is hilly and mountainous, and the soil generally fertile. Capital, Hiwassee.

TOWNLEY, CHARLES, an English collector of works of ancient art, born in Lancashire in 1737, died in 1805. Being of a Roman Catholic family, he received his education abroad; and during a residence in Rome between 1765 and 1772 he devoted a large portion of his private fortune to the purchase of ancient marbles, terra cottas, bronzes, gems, &c., in which he was aided by the advice and experience of Winkelmann and other competent judges. After his return to England, he continued to add to his collection by means of agents at Rome, and by the purchase of the collection formed by Nollekens, as also of such desirable specimens as were offered for sale in England. After his death his collection of marbles and bronzes was purchased by the nation for £20,000, and in 1814 his bronzes, coins, and gems became the public property at a cost of £8,200. The whole collection was deposited in the British museum, and until the erection of the present building the marbles occupied a special suite of rooms called the Townley gallery. They are now incorporated with the general collection of Græco-Roman remains, of which, both as regards extent and character, they form the most important part. They belong to all periods of ancient art except the earliest; and the best specimens are either original works by Greek artists, executed in the early times of the Roman empire, or copies of works by celebrated early Greek masters. The most remarkable of these are the Venus or Dione, found in the baths of Claudius at Ostia in 1796, the *Discobolus* or quoit thrower, supposed to be a copy of the famous bronze statue by Myron; the well known "Drunken Faun," and other

statues; two colossal busts of Pallas and two of Hercules; portrait busts of Homer, Perianther, Pindar, Sophocles, Hippocrates, Epicurus, and Pericles; and the exquisite female head rising from the petals of a water lily, known as the Olytia, of which numerous repetitions have been made in plaster and marble. The bas-reliefs are fine, and include Achilles, the Muses, and a graceful figure of a Bacchante.

TOWNSHEND, CHARLES, second viscount, an English statesman, born in 1676, died in Rainham, Norfolk, June 21, 1738. He succeeded to his title at 10 years of age, and soon after taking his seat in the house of peers attached himself to the whigs, to whose principles he remained faithful during his whole career. In 1705 he was appointed one of the commissioners to treat for the union with Scotland, and in 1707 captain of the yeomen of the queen's guard; and in 1709, in the capacity of ambassador extraordinary to the United Provinces, he concluded the barrier treaty, for which he was denounced in the house of commons in 1712 as an "enemy to the queen and kingdom." The accession of George I. having brought the whigs into power, Townshend was appointed one of the principal secretaries of state, and took the lead in the administration until the summer of 1716, when, owing to the intrigues of his colleagues in the ministry, Lord Sunderland and Gen. Stanhope, he was dismissed from office. To break the ignominy of his fall, he was offered the lord-lieutenancy of Ireland, which he indignantly declined; but the king, fearful of the effect of his dismissal upon the public mind, prevailed upon him to accept the office, promising that it should soon be exchanged for a more influential one. The growing influence of Sunderland and Stanhope with the king, however, rendered the position of Townshend an uncomfortable one, and, with his colleague and brother-in-law Walpole, he retired from office in April, 1717. After remaining for several years in opposition, he was in 1720 appointed president of the council, and upon the reconstruction of the ministry in 1721 he resumed his old position of secretary of state, Walpole becoming first lord of the treasury and chancellor of the exchequer. For several years the two ministers cooperated harmoniously in their administrative duties; but the growing ascendancy of Walpole gradually excited the jealousy of Townshend to such a degree, that almost every question of public policy entertained by the government became the subject of a dispute between them. Finally, after an unusually angry interview, in which they are said to have proceeded to blows, Townshend resigned office on May 15, 1730, and, retiring to his seat at Rainham, devoted the remainder of his life to rural pursuits. Among the improvements which he promoted in agriculture was the introduction of the turnip husbandry. He was a man of ability, though an indifferent speaker, and left office, says Lord Mahon, "with a most unblemished character, and—what is

still less common—a most patriotic moderation." He was somewhat overbearing in manners, and of an impetuous and irascible temper.—CHARLES, an English statesman, grandson of the preceding, born Aug. 28, 1725, died Sept. 4, 1767. He displayed in youth great quickness of conception, but, as in after life, was remarkable for unsteadiness of purpose and defiance of discipline. He entered parliament in 1747 as member for Yarmouth, for which place he sat until 1761, when he was elected for Harwich, and in 1753 brought himself into notice by a speech of great power and eloquence on the marriage bill. In 1754 he was appointed a lord of the admiralty, and in the first administration of Pitt he held the office of treasurer of the chamber, which in 1761 he exchanged for that of secretary of war. During the ministry of the earl of Bute he remained out of office, but in that of George Grenville which succeeded, he was appointed first lord of trade and the plantations. He zealously supported Grenville's stamp act, introduced in 1765, in a speech which elicited from Col. Barré in reply one of the most memorable efforts of parliamentary eloquence; but during the Rockingham administration, in which he held the office of paymaster of the forces, he advocated the repeal of the act. Upon the formation of the second Pitt administration in 1766, he became chancellor of the exchequer, and, with a vacillation of policy which gained him the name of the weathercock, advocated the necessity of a tax being laid upon American ports. On June 2, 1767, he introduced into the house of commons the celebrated resolutions imposing duties upon paper, tea, and other articles imported into the American colonies, which eventually led to their revolt and independence. The illness of Pitt, now earl of Chatham, and the consistent opponent of American taxation, rendered necessary a reconstruction of the cabinet, and Townshend was generally understood to have been selected to form a new ministry. But just as the prize seemed within his reach, he was carried off suddenly by a putrid fever. His parliamentary abilities and oratorical powers have been forcibly illustrated in a memorable passage in Burke's speech on American taxation, in which he is described as "that prodigy, Charles Townshend, the delight and ornament of this house and the charm of every private society which he honored with his presence."

TOWNSHIP. See TOWN, and SURVEYING.

TOWSON, NATHAN, an American soldier, born in Maryland in 1784, died in Washington, D. C., July 20, 1854. He was appointed a captain in the 2d regiment of artillery in March, 1812, and on Oct. 8 of that year, aided by Lieut. Elliot of the navy, captured the British brig *Caledonia*, under the guns of Fort Erie. He was wounded in 1818 at Fort George, Upper Canada; and in 1814, being in command of a battery in Gen.-Brown's army, which crossed to the Canada shore, he greatly distinguished himself for bravery and efficiency,

driving the advance guard of Gen. Riall back beyond Black creek. In the battle of Chippewa he again led the van, and in the severe battle of Niagara for the third time received the highest commendation for his gallant conduct. In the defence of Erie on Aug. 15 he still further distinguished himself. In May, 1816, he was promoted to a lieutenant-colonelcy by brevet, and in 1819 appointed paymaster-general. In 1834 he received the brevet of brigadier-general, and in 1849 that of major-general, for meritorious services in the Mexican war.

TOXICOLOGY. See POISON.

TOXODON (Gr. *toxon*, a bow, and *odon*, a tooth), a name applied by Owen to a genus of extinct mammals of the order pachyderms, with affinities to edentates and rodents. The first species, named by Owen the *T. platensis*, was found in a miocene clay in South America, about 120 m. N. W. from Montevideo; it was established on a cranium $2\frac{1}{2}$ feet long, elongated, with a flattened occiput, small cerebral cavity, remarkably strong and widely expanded zygomatic arches, and transverse glenoid cavity; the upper molars were 7 in number on each side, implanted with the convexity outward, the opposite of what occurs in rodents; they were long, arched, without roots, the enamel forming an irregular prismatic grooved tube; upper incisors 4, the external the largest, like those of rodents in structure, and worn away in the same chisel shape; in the lower jaw were 7 molars on a side, and 6 incisors ranged in a semicircle; the name was derived from the curve of the outer upper incisors. It was an animal of large size, low on the legs, with the aspect and habits of a pachyderm. Resembling the rodents in the form of the incisors, it differs from them in their number, in the shape of the skull, and in the transverse glenoid cavity; it shows an affinity to the aquatic pachyderms (like the manatee) in the flattened occiput, small brain cavity, and nasal passages widely opened above, but differs in the size of the frontal sinuses and in the incisors; its heavy form and its molars bring to mind the gigantic fossil edentates, from which the incisors distinguish it; it seems to have been an animal connecting the pachyderms with the rodents. The depth of the zygomatic arches indicates the great size of the temporal muscles acting on the large incisors, probably used, like the canines of the hippopotamus, in dividing and pulling up the roots and stems of aquatic plants growing on the banks of rivers; it was probably aquatic in its habits to a certain extent. For a detailed account of the genus, see "Fossil Mammals of the Voyage of the Beagle," described and figured by Prof. Owen (4to., London, 1840).

TRACERY, in architecture, the ornamental pattern work traced in the head of a Gothic window by causing the mullions to diverge into various fanciful shapes, enriched with foliations. The tracery of windows, as also of battlements or parapets, is perforated for the

purpose of admitting the light, whence it is sometimes called open-work. When work of this character is applied to ceiling or panellings, it merely represents a pattern carved on a solid surface in the nature of bass-relief.

TRACHEOTOMY, a surgical operation by which the trachea or windpipe is opened. Tracheotomy may be performed with propriety in those cases where, from disease of the larynx, or upper portion of the air passages, such as croup, acute laryngitis, cedema, glottitis, quinsy, pressure from tumors or other causes, and diphtheria, the admission of air into the lungs is obstructed, and there is danger of suffocation. It may also be proper where some foreign body has become so fixed in the air passages as to completely obstruct the transmission of air through the trachea; and it has sometimes been tried with success to facilitate the inflation of the lungs in cases of suspended animation. The operation is not free from danger, and in the first class of cases, though giving marked temporary relief, it does nothing toward curing the disease itself. It consists in first making an incision in the median line of the throat, either below or above the thyroid gland, and dissecting down to the trachea, cautiously pushing aside the sterno-hyoid muscles and vessels lying in the vicinity, till the trachea is exposed. When the bleeding has ceased, the trachea is opened by a vertical incision, and a portion of one or more of its rings removed; through the opening thus made, a silver canula is introduced, which when obstructed by mucus may be removed, cleaned, and again inserted. If the obstruction to respiration is removed, the canula may be withdrawn and the orifice allowed to heal; but if not, the canula must be worn for life. If the operation is performed to aid in restoring animation or to remove a foreign body, no canula need be inserted, and the wound should be closed so soon as the object is effected.

TRACHYTE (Gr. *τρᾶχυς*, rough), a rock of oceanic origin, named from the roughness of its surface. It consists chiefly of glassy feldspar, sometimes associated with hornblende, and also with augite. When these minerals predominate, the rock passes into the varieties of trap called basalt, greenstone, dolerite, &c.

TRACT AND PUBLICATION SOCIETIES. The practice of printing short religious treatises, essays, and narratives for cheap or gratuitous distribution was very early adopted. Indeed, prior to the introduction of printing, Tyndale circulated his views by means of brief sayings, which were passed from hand to hand, and often transcribed by those who were anxious to preserve them. Strype testifies to the circulation of some of Tyndale's tracts about 1530. In the 17th century there were some societies for printing and promoting the sale of religious works. In 1701 the "Society for Promoting Christian Knowledge" was founded, and its objects were declared to be: "1, to promote and encourage the erecting of charity

schools in all parts of England and Wales; 2, to disperse both at home and abroad Bibles and tracts of religion, and in general to advance the honor of God and the good of mankind by promoting Christian knowledge, both at home and in other parts of the world, by the best methods that should offer." This society, which by its regulations was confined to members of the church of England, promoted from the first the circulation of large numbers of small books and tracts among the poor and vicious. In 1742 John Wesley began the publication and distribution of tracts and books on a large scale, and was the first to set the example of modern cheap prices sustained by large sales. In 1782 he and Dr. Coke organized the "Society for the Distribution of Tracts among the Poor." In 1750 the "Society for Promoting Religious Knowledge among the Poor" was organized at London, and was the first publishing society in which members of different religious denominations were united for the promotion of the circulation of religious books and tracts. In 1756 societies were established at Edinburgh and Glasgow for similar objects, and for several years circulated many religious publications; but eventually they as well as the London society declined and became inefficient. In 1795 Miss Hannah More commenced at Bath a series of small religious publications which she named "Cheap Repository Tracts," of which 2,000,000 were sold the first year. Among them was the widely popular story of "The Shepherd of Salisbury Plain." Mrs. Rebecca Wilkinson, of Clapham, Surrey, also wrote and published many small books and tracts. The philanthropic society printed for her in the course of a few years, commencing with 1792, 440,250 copies of books and tracts.—In 1798 the "Religious Tract Society," or as it is now called the "Religious Tract and Book Society of Scotland," was instituted. The Rev. John Campbell was its founder, and was led to establish it by his observation of the efforts of the Rev. Charles Simeon of Cambridge in that direction, and by some experiments he had made in issuing a few tracts for circulation himself. In 1855 this society adopted with some modifications the colportage system of the American tract society, and has since prosecuted it with great success. Its expenditures for colportage and gratuitous tract distribution in 1861 were £768 3s. 10d. The amount of its sales we have not been able to ascertain.—The "Religious Tract Society" of London was founded in May, 1799. It had its origin in the labors of the Rev. George Burder, minister of a congregation at Coventry, who had commenced printing tracts on his own account in 1781, of a more directly religious character than those of Miss More. He continued their occasional issue in connection with some friends for several years, intrusting the charge of their publication to a London bookseller, who eventually failed and caused the authors of the tracts considerable loss. Mr. Burder, believing that

a more extensive agency and a larger investment were desirable, then convened a meeting of ministers by whom the society was established under its present name. Among its founders, beside Mr. Burder, were the Rev. Messrs. Rowland Hill, William Newman, Matthew Wilks, and Joseph Hughes, for many years its secretary. Its entire receipts the first year were £467 7s. 4d., of which £208 10s. 8d. was from contributions, &c., and £268 16s. 8d. from sales. In 1849 they had risen to £50,981 15s. 8d., of which £4,989 2s. 8d. was from contributions, &c., and £44,603 16s. 6d. from sales. The total receipts of 50 years from contributions and legacies, up to 1849, were £152,552 8s., from sales £1,028,915 18s. 1d., making with other items £1,202,249 18s. 8d. By the expenditure of this sum the society had published 5,148 different works in 110 languages and dialects, of which it had issued over 500,000,000 copies. It now keeps in stock 6,780 different publications suited for circulation and distribution, of which 701 are books for adults, 1,268 books for the young, 2,122 tracts, and 6 periodicals, and the remainder cards, handbills, &c.; and it issued in 1861 41,883,921 copies of volumes and tracts. Its total receipts the same year were £108,127 16s. 11d., of which £14,437 12s. 8d. was from contributions and legacies, and £88,690 4s. 3d. from sales. The whole number of volumes and tracts issued from its organization to March 31, 1861, was 912,000,000, and the whole number of publications was 7,983, in 114 different languages and dialects. Its grants for 1861 of books, tracts, and money, amounted to £12,453 11s. 8d. This society owns no presses or bindery, the manufacture of its books and tracts being contracted for. It maintains three depositories in London, viz.: a wholesale department at No. 56 Paternoster row, a retail department at No. 65 St. Paul's Churchyard, and a western depository at No. 164 Piccadilly, near St. James's street. Apart from these, its publications are mostly circulated through auxiliary societies, which establish local depositories, colporteurs and book hawkers who traverse the country with them, and the book trade, many of whom keep a supply of its books. In foreign countries they are sometimes kept by booksellers, but oftener distributed through missionaries or their assistants. There are several other societies in Great Britain for

the circulation and distribution of religious books and tracts, each of the principal religious denominations having one or more.—In the United States, the diffusion of religious books and tracts was early regarded as important, and the publications of the Christian knowledge society and of some of the other societies above named were sent from England for distribution in considerable quantities. The first religious publication society in this country was the "Methodist Book Concern," originally established in Philadelphia, and which issued its first publication in 1789. It was removed to New York in 1804, and for 29 years had its depository in Crosby street. In 1822 the agents established a bindery, its publications having previous to that time been manufactured by contract, and in 1824 added a printing office. In 1838 it was removed to No. 200 Mulberry street, and in Feb. 1836, its premises were destroyed by fire, and a loss of \$250,000 incurred. In 1844 the division of the Methodist church led to the organization of a book concern connected with the Methodist church south, at Nashville, Tenn., which eventually received \$200,000 of the capital of the book concern as the share of the church south. The number of distinct works it now publishes is 1,967 bound volumes and 2,096 tracts. The publications of the book concern are divided into 3 classes: 1, publications of the general catalogue, mostly bound volumes, though including some pamphlets, and including also the denominational newspapers and periodicals; 2, those of the Methodist Episcopal Sunday school union, which was organized in 1827 and reorganized in 1840, and all the publications of which are printed and issued by the book concern; and 3, those of the Methodist Episcopal tract society, also issued through the book concern, and which have amounted annually for the past 5 years to 10,928,580 pages. Both the Sunday school union and the tract society have periodicals devoted specially to their objects; those of the former, 8 in number, have a combined circulation of 248,000 copies, and that of the latter 58,000. The book concern has a depository in Cincinnati, which publishes periodicals and a few books; it has also depositories publishing denominational journals, and keeping full supplies of its books, at Boston, Pittsburg, Chicago, St. Louis, and San Francisco; and the min-

tem, which it has maintained up to the present time. The *colporteur*, as the term is employed by the society, is not simply a book hawker or peddler, but an itinerant missionary, who enters upon the work of distributing its publications either by sale, partial sale, or gift, as may seem best in each case, from the desire to do good; his expenses are partially met by the society, and partially defrayed by the sales of books. The society estimate the cost of maintaining a colporteur annually in the country at \$262.41, and in the city at \$367.56; but as his labors are in many particulars similar to those of a home missionary, in the establishment of religious meetings, Sunday schools, family worship, and the promotion of temperance and social order, especially in the newer states and territories, the expense of the enterprise is no valid objection to it. In 1860-'61, 576 colporteurs served the society for a period equal to the labors of one man for 282 years, in 32 states, the District of Columbia, the Choctaw nation, Canada West, and Prince Edward's Island. The entire expense of the colportage operations of the society for 1860-'61, inclusive of superintendence, &c., was \$99,105.06. The following is a portion of the work performed by its colporteurs for 20 years: time employed, months, 44,097; number of volumes sold, 7,272,598; volumes granted, 2,098,469; public meetings addressed and prayer meetings held, 201,417; family visits, 8,889,807; families destitute of religious books except the Bible, 741,778; families destitute of the Bible, 460,249; families habitually neglecting evangelical preaching, 1,124,630.—The various religious denominations have each also their tract or publication societies, and many of them issue a considerable number of publications. The table on the two preceding pages gives the most important particulars concerning some of them, up to the close of their last financial year.

TRADE. See COMMERCE.

TRADE MARKS, particular marks or signs which a trader affixes to his goods and manufactured articles, to enable the public to distinguish them from other similar goods or articles. The law in relation to trade marks is very recent both in England and the United States, though a case sustaining its principle occurs as long ago as the 22d of Elizabeth (1580). Though it does not arise from nor depend upon, and is not regulated by, statutory provisions, it is like the law of patents in its general purpose, which is to protect a man in the enjoyment of all reasonable advantages derivable from his superior skill or integrity, and the reputation he has won thereby; and in administering, or rather in making and developing the law of trade marks, courts have adopted many of the principles and rules of the law of patents. The leading principles established by the decisions of the courts appear to be as follows: 1. Every manufacturer, and also every merchant or

trader for whom the goods are manufactured and whose business it is to sell them, may put upon the goods which he manufactures, or which are manufactured for him to sell, whatever peculiar mark or device he chooses, for the purpose of so identifying the goods he makes or sells, that the public, or all who purchase or use them, may readily distinguish them from other goods. 2. When such mark is adopted and used, no other person has the right to assume or use this mark. 3. The intention of the manufacturer or merchant in using the mark, and the effect of the mark itself, must be, not to express or indicate the excellence of the goods, or any peculiarity in their quality, or give them a certain name; for so far as trade marks do only this, no one can have an exclusive right to or in them; but the intention and effect of the mark must be to indicate their origin and ownership, and connect them with the manufacturer or trader, as it were personally. 4. A violation of this right to a trade mark must (as a consequence of the last stated principle) be, not a mere endeavor to persuade the public that the goods of him who uses it after another are equally valuable with those of him who first appropriated and used this trade mark; but it must be a false adoption of a mark, with the intention and effect of persuading the public that the goods are actually the goods of the manufacturer or trader whose mark it is. 5. The violation is sufficient in law, if it does not adopt and repeat precisely the original trade mark, but only imitates this, with the intention that it should be regarded as the original; and it is said that this kind of violation of the right of the proprietor is complete when the imitation is so close that a careful examination is required to enable a purchaser to distinguish between the true and the simulated trade mark; and any thing is a violation of the right which has this effect. Hence the transfer of the trade mark of the plaintiff from a superior article of his manufacture to an inferior article also of his manufacture, but which bore usually a different mark, has been regarded as a fraud both against the public and against the manufacturer. 6. It is no excuse or justification for the use of another person's trade mark, that he who thus falsely uses it communicates the fact to his purchasers, who therefore are not deceived; because by using falsely this trade mark, he enables those who purchase from him to deceive those who purchase from them, and he may reasonably be supposed to have intended this; and the injury to the actual proprietor of the trade mark is the same. 7. The rule, and the principles which govern its application, appear to be extended to all kinds of property held by the owner for the use of the public with compensation to him, and in which there can exist a peculiar and personal right of appropriation. Thus, it has been held that a public conveyance, as a stage coach or omnibus, may have a good will at-

tached to it of a beneficiary nature; and if it be distinguished by a peculiar device or sign, no one will be permitted to draw this good will away by a fraudulent imitation of this device or sign. 8. One whose exclusive right in his own trade mark has been violated, may have his remedy at law or in equity. At law, by a suit for damages; and they will be measured by the loss of sales to the owner, and by the injury done to the reputation of his business or his merchandise. It may not be quite certain whether a jury may give vindictive or punitive damages, that is, may swell their damages beyond actual compensation to the plaintiff by way of punishment to the defendant. It is however clear that the jury would have a wide reach in estimating the injury he has sustained in his business. It has been held, and may be regarded as a prevailing rule, that the plaintiff cannot recover damages for past sales, unless the defendant intended to deceive, or at least knew that he was selling good; which bore the plaintiff's marks. But whether the defendant was or was not ignorant of this, the plaintiff may still have his remedy in equity. This remedy consists mainly, if not altogether, of an injunction against the defendant, which shall prevent his making any further use of the plaintiff's trade mark. The plaintiff may generally resort both to legal and equitable remedy; and it appears that where the fact of the violation of the right is doubtful, equity will not give relief by way of injunction, until this fact of violation has been determined by an action at law. 9. It is a very important rule, that aliens may sue for a breach of their exclusive right to their own trade marks; and some of the most instructive and interesting actions to vindicate this peculiar right have been brought by aliens before the courts of some of the United States; as by Taylor, an English manufacturer, against Carpenter, a citizen of the United States, for a fraudulent use in this country of the plaintiff's trade mark of "Foster's Persian Thread;" by Coats, another English manufacturer, against Holbrook, about Coats's thread; and by Gillott, an English steel pen maker, against Kettle, for putting the mark appropriated by Gillott to his pen "No. 808" to his pen "No. 753," which was a cheaper pen of inferior quality.

TRADE WINDS, atmospheric currents moving with great uniformity toward the equator to fill the spaces left by the airs that have become heated and passed up to the more elevated portions of the atmosphere in the belt of the equatorial calms. These currents, moving continually toward larger parallels of latitude, do not at once acquire the increasing eastwardly movement of the portions of the earth's surface revolving beneath, and the lagging occasioned by the earth slipping away under them produces a deviation from a direct meridional movement as respects the surface of the earth, and an apparent progress of the currents toward the west. Thus the course of these

winds in their range N. of the equator is from the N. E., and S. of the equator from the S. E.; and the two systems are known respectively as the N. E. and S. E. trade winds. Near their commencement they partake more of the easterly character, and as they approach the equator they move more upon the meridians. They disappear in the belt of calms, or the "doldrums," the limits of which vary with the seasons, the N. border being sometimes in lat. 4° and sometimes 10° or 12° N., and the S. border in lat. 3° N., and at other times a few degrees S. of the line; the average width of the belt is about 6° . The S. E. trade winds, when the sun is in the northern hemisphere, may thus blow across the line; and the N. E. trades when the sun is S. may reach within 4° of it. The points where these winds originate in the northern hemisphere are from 25° to 32° from the equator, varying with the seasons; and thus these winds in the latitudes included between the degrees named have the character of periodical winds. In the southern hemisphere the trade winds, when the sun in its S. declination approaches the tropic of Capricorn, are felt as far as lat. 30° S., and their N. limit is then about lat. 1° N. The general width of the belt of the S. E. trades is about 9° greater than that of the N. E. trades. The trade winds are greatly affected by the proximity of land as well as by the change of the seasons. In the Atlantic ocean off the coast of Africa the influence of the hot desert regions in the interior is so powerful, that for 50 to 80 m. out to sea the prevailing winds are from the W., and the regular trades are not fallen in with until outside of this influence. In the Pacific ocean the steady S. E. trades do not blow within about 500 m. of the coasts of Peru and Chili, the general direction of the winds in this space being from the S., parallel with the coast. The effect of the hot districts of Asia in modifying the N. E. trades is noticed in the article *Monsoon*. The numerous islands and shoals in the Pacific produce great irregularities in the direction and strength of these winds, which where no such disturbing causes exist blow with remarkable constancy and steadiness; and it is by the facilities they thus afford to navigation that they have acquired the name of trade winds. By taking advantage of them, vessels may run a regular course often for weeks together without shifting a sail, and all the time enjoying delightful weather, which everywhere prevails under the regular trades. This course may be before them or obliquely across their line in either direction. Where their regularity is disturbed by local causes at certain seasons, as in the periodical changes of the monsoons, terrific storms are of frequent occurrence, alternating with periods of calms and light variable breezes. At these times are experienced the most violent extremes of heat, rain, tornadoes accompanied by waterspouts, and the most vivid displays of lightning and awful bursts of thunder. The region about

Madras in India is particularly exposed to the violence of these phenomena, which recur every 6 months. Vessels at these periods avoid the coasts; and so violent are the storms of wind, that even the fish from the sea are often found upon the tops of the houses, being blown off from the waves or carried up by the water-spouts and then blown inland. Though in general the trade winds from local causes lose their marked characteristics upon the land, there are in the equatorial regions of South America vast plains at a low elevation, as those of the Amazon and the Orinoco, where the conditions are favorable for the prevalence of atmospheric currents which depend in their origin and continuance upon general causes, as the rotation of the earth and the relative temperatures of different zones; and accordingly in these regions constant winds from the E. are encountered, which up the Amazon especially blow with great force across the continent as far as the hilly country at the base of the Andes. A strong wind from the E. also blows continuously over the W. portion of the desert of Sahara, which is known as the *sahel*; and in the E. part winds prevail from the same quarter, but are more like the trade winds from their diminished force and somewhat fluctuating character.—The trade winds were unknown to the ancients; they were first observed by Columbus in his first voyage to America. He fell in with them soon after leaving the Canary islands; and his vessels in the favorable breeze, which changed not from day to day, were wafted rapidly across, much to the alarm of his sailors, who saw no prospect of making their way back against winds thus blowing always in the same direction. It was at last by taking a course through more northern latitudes, that Columbus, who had probably gained some knowledge of the trade winds in his previous excursions to the Canary islands, succeeded in avoiding them on his return voyage. The early navigators in the accounts of their voyages dwelt with much interest upon the delightful atmosphere of the region of these winds, and were reminded by the balmy air and unclouded skies of the most perfect days of the fine climate of Andalusia.—The true explanation of the trade winds was first proposed by George Hadley in the "Philosophical Transactions" for 1735. Galileo had previously associated their movement with the rotation of the earth, but did not arrive at a clear understanding of the phenomenon, especially in its relation to the heat of the equatorial belt, the region of calms there existing, and the vibration of the range of the winds N. and S. with the change of the seasons. Hadley explained the effect of the winds in their progress toward the equator not immediately acquiring the more rapid motion of the surface of the earth, due to its increasing diameter, and thus in fact falling behind with an apparent easterly movement; and Capt. Basil Hall, in his "Fragments of Voyages and Travels," was the first

to show that on this principle the winds when near the equator, and passing over diurnal circles of very slowly increasing radii, should acquire the rotatory movement of the surface and appear only as meridional winds, which is the case in the latter portions of their course.—It is an interesting question as to the subsequent destination of the vast bodies of air that continually collect from the N. and the S. in the equatorial belt, and are carried upward as their density diminishes through the heat they absorb. That they must be returned in some manner to the localities whence they came, in order to keep up the never ceasing currents, cannot be doubted; and evidences of a counter movement in the upper regions of the atmosphere are occasionally observed when clouds appear in the usually clear sky of the trade winds, their motion being contrary to that of the winds at the surface. It has also been observed that upon the highest portions of the Canary islands during the prevalence of the trade winds, the wind blows continually from the W. and with considerable force. Humboldt noticed the same phenomenon at the top of the peak of Teneriffe, a strong S. W. wind there blowing while the N. E. trades prevailed over all other portions of the island. But the most remarkable incident bearing upon this question was the precipitation in 1812 upon the island of Barbados of volcanic ashes carried through the air from the volcano of St. Vincent, then in eruption, about 80 m. to the W. These matters, it is evident, must have been thrown up from the crater above the level of the trade winds into a current moving in the opposite direction, by which they were wafted beyond Barbados to the E., and then descending were brought back by the trade winds to this island. Mr. Maury, in his "Physical Geography of the Sea," advances a theory that the airs brought from the S. cross those from the N. as they ascend in the equatorial belt, the two sets by some unknown influence keeping distinct from, though intermingling and passing through each other, and each upper current again descends to the surface on reaching the tropic of Cancer or of Capricorn, passing through an upper current moving in an opposite direction, which on descending becomes the trade wind moving toward the equator. He imagines that beyond the tropics the general movement of the surface winds is toward the poles, where, all meeting as upon the equator, an upward and rotatory movement takes place in which the currents again pass through each other and return to the tropics on the opposite side of the globe as an upper current.—The trade wind belt is bounded toward the poles by a region in which the winds are variable, those from the W. generally prevailing. In the northern hemisphere they are not so regular as in the southern. It is in this region that the Atlantic is crossed by vessels passing between New York and Liverpool; and it is noticed of the passages made by the packets

for a period of 6 years, that the average length from New York was 28 days, and from Liverpool 38 days.

TRAGOPAN, a name given by Cuvier to the birds of the pheasant family comprised in the genus *coriornis* (Swains.). The bill resembles that of the common fowl; the wings are ample and very concave, with the 4th to the 7th quills the longest; tail rounded, and its coverts ample; tarsi stout and armed with a small spur, anterior toes united at the base by membrane, and the claws long and curved. There are 8 or 4 species, inhabitants of the gloomy and thick pine forests of the high mountains of central Asia; they are solitary and shy, and discoverable only by their shrill whistle; the plumage is very brilliant, being red, varied with black, blue, and golden, and with white eye-like spots. The best known species is the horned pheasant (*C. satyra*, Swains.), of the size of a large domestic fowl; the males have the sides of the head naked, and in the spring behind each eye a long horn of a reddish and bluish color directed obliquely backward, and under the throat long, naked, bluish, expansile wattles; the feathers are lengthened and disunited on the crown, purplish black, becoming crimson on the occiput; back of neck and bare skin in front surrounded by deep black; wings and back brown with an eyed white spot at the end of each feather; rest of plumage deep red with small spots of white; the female and young are brownish, and have neither the horns nor the wattles; the males do not attain the full beauty of their plumage till the 8d year. The food consists of grains, roots, insects, and larvæ. This is probably the tragopan mentioned by Pliny. The golden-breasted and the black-headed tragopans, of the same size and similar habits, are sufficiently characterized by their names, the plumage being in other respects not very unlike.

TRAGUS, HIERONYMUS, the Latin name of a German botanist, whose real name was Bock, born in Heydesbach in 1498, died in Hornbach in 1553. He received a classical education, and became head of a school in Deux Ponts, and superintendent of the ducal garden. Having embraced the reformed religion, he became pastor of a church in Hornbach, and afterward was physician of the count of Nassau in Saarbrück. He devoted himself to the study of botany, and in 1551 published *Neues Kräuterbuch vom Unterschiede, Wirkung und Nahmen der Kräuter, so im Deutschland wachsen* (fol., Strasbourg). This was the first attempt made in modern times toward the classification of plants.

TRAJAN (MARCVS ULPIVS TRAJANVS), a Roman emperor, born, according to some authorities, in Italia, the modern Alcala del Rio on the Guadalquivir, not far from Seville, Spain,

Sept. 18, A. D. 53, died in Selinus (afterward called Trajanopolis), Cilicia, in Aug. 117. He was the son of Trajanus, an officer in the imperial service, and early embraced the profession of arms. He served as a military tribune in the wars of the East, probably directly under his father, before 86 was made prætor, and in 91 became consul along with M. Acilius Glabro. After discharging the functions of this office he went to Spain, and was ordered by Domitian to go to Germany and command the troops on the lower Rhine, the headquarters of his department being at Cologne. Although little is known of his early history, he must have become distinguished and popular, for when at the close of 97 Nerva adopted him and chose him as his successor, the selection met with general acquiescence both among the people and the soldiers, although none of the previous emperors had been born out of Italy. His title after his elevation to the imperial dignity was Imperator Cæsar Nerva Trajanus Augustus. In Jan. 98, Nerva died, and Trajan, who was then encamped at Cologne, succeeded to the throne; but for many months he did not go to Rome, being engaged in settling the commotions which had disturbed the security of the frontiers of the Rhine and the Danube. He entered Rome amid the acclamations of the people, and soon proved by his conduct that the hopes raised at his assumption of the purple were destined to be fulfilled. He received the title of Pater Patriæ, and was also honored with the new designation of Optimus. He bestowed a gift of money on the soldiers and also on the Roman citizens; made provision for supporting the children of the poor; victualled Rome by allowing the entrance of grain free of duty; issued edicts against informers; curbed the insolence of the prætorian troops; and appointed men of high character to public offices. In 100 the younger Pliny, who was the warm personal friend of the monarch, pronounced his panegyric upon him. In 101 Trajan left Rome for the purpose of carrying on a war against Decebalus, king of the Dacians, who had obliged Domitian in a previous struggle to buy peace by making an annual payment of money. Trajan crossed the Danube, defeated the Dacian monarch, took many of his strong posts and his capital Sarmizegethusa, and, having compelled him to sue for peace, returned to Rome in triumph with the title of Dacicus. In 104 Decebalus broke his treaty, refused to comply with the emperor's demand that he should surrender himself, and when Trajan marched against him first attempted to save himself by sending two men to poison his enemy under the pretence that they were deserters. The conquest of Dacia was now determined upon, and an immense bridge was built across the Danube, over which the Roman army passed into that country. This bridge was the largest work of the kind ever built by the ancients, and, according to the statement of Dion Cassius, consisted of 20

piers, 150 feet high, 60 feet wide, 170 feet apart, and united by wooden arches, and was probably in the neighborhood of the modern town of Tchernetz in Wallachia. Trajan was successful in this campaign in spite of the numerous obstacles to be met with in a country unknown, inimical, and having no roads. Decebalus was defeated at all points, and in despair killed himself; Dacia was reduced to the condition of a Roman province, and fortified posts were built and colonists settled in it. When the emperor returned to Rome, he exhibited to the people games which lasted 123 days, and in which 11,000 animals were killed and 10,000 gladiators fought. In 106 he went on a campaign against the Parthians and Armenians, and was engaged during the following years in numerous military expeditions, the history of which is almost altogether lost. In the year 112 occurred his 6th and last consulship. In the spring of 115 he marched against the Parthians, having previously received the submission of Armenia and the princes of the neighboring countries. He crossed the Tigris on a bridge of boats, subdued the country beyond that river, and returned to Antioch the same year; and while there a great earthquake occurred from which Trajan barely escaped with his life. In the following year he again marched to the Tigris, and sailed down that stream to the Persian gulf, but was recalled by a general uprising in the provinces which he had reduced. Arriving at Oesiphon, he gave the Parthians a king whom that turbulent people quickly expelled. After the siege of Atræ in Mesopotamia, he fell sick, and, leaving his successor Hadrian in command in Syria, started for Italy, but died on the way. His ashes were carried to Rome in a golden urn, and placed under the column bearing his name, which he had caused to be erected in honor of his Dacian victories.—Our knowledge of the events of Trajan's reign is very imperfect and unsatisfactory, but we know that for many generations afterward it was looked upon as the most brilliant in the imperial annals. The Roman arms were carried further than ever before or after, and rarely suffered defeat. Beside the conquests in Dacia and beyond the Euphrates, Arabia Petraea was made subject to the empire by A. Cornelius Palma, the governor of Syria. Nor were his works for the internal improvement of his dominions less important. He constructed an artificial harbor at Centum Cellæ (now Civita Vecchia), built the port of Ancona, made several great roads in various parts of the empire, one of which was across the Pontine marshes, and erected magnificent bridges. He founded several libraries in Rome, one of which, called *Ulpia Bibliotheca*, was very celebrated; built a theatre in the Campus Martius, and also the Forum Trajanum, his great work, in the centre of which was the column of Trajan, erected in 112. It has been alleged that his private character was disfigured by intemperance and

licentiousness. Many writers doubt the magnitude of the persecution of the Christians which is said to have taken place during his reign. His correspondence with the younger Pliny, governor of Bithynia and Pontus, concerning the treatment of the members of that sect, displays in his character an unusual consideration for justice and humanity. In his reply to Pliny he says: "You have adopted the right course, my friend, with regard to the Christians; for no universal rule, to be applied in all cases, can be fixed in this matter. They should not be searched for; but when accused and convicted, they should be punished; yet if any one denies that he has been a Christian, and proves it by action, namely, by worshipping our gods, he is to be pardoned upon his repentance, even though suspicion may still cleave to him from his antecedents. But anonymous accusations must not be admitted in any criminal process; it sets a bad example and is contrary to our age." The conquests of Trajan were abandoned by his successor Hadrian, who restored the empire to its former limits; but his memory was long cherished by the Romans, and 200 years later the senators were in the habit of saluting the emperor with the acclamation: "Be happier than Augustus and better than Trajan." The best modern authorities for the history of his reign are his life in Tillemont's *Histoire des empereurs*, and H. Francke's essay *Zur Geschichte Trajans und seiner Zeitgenossen* (1837).

TRALL, RUSSELL TEACHER, M.D., an American physician, born in Vernon, Tolland co., Conn., Aug. 5, 1812. His parents removed to western New York in his childhood, and he was destined for the life of a farmer; but ill health led him to the study of medicine, and for some time he practised the profession in accordance with the principles of the standard medical writers. In 1840 he removed to New York, and after acquiring a knowledge of the theories and practice of the homeopaths, the hydropathists, the disciples of Sylvester Graham, &c., he came to the conclusion that the use of drugs for medicinal purposes was injurious under all circumstances, and contrary to the laws of nature; and that water, air, temperature, light, exercise, rest, sleep, food, and passional influences were the only true remedies for disease. He gave considerable prominence to water as a remedial agent, but excluded all drugs from his practice. In 1843 he opened a water-cure establishment in New York, over which he still presides; and in 1853 he established in connection with it a medical school for pupils of both sexes, which was chartered in 1857, under the name of the "New York Hygeio-Therapeutic College." This institution is authorized to confer the degree of M.D., and has since its organization given diplomas to about 200 graduates, $\frac{1}{3}$ of them females. Dr. Trall is the professor of theory and practice in this college. From 1845 to 1848 he was editor of the "New York Organ," a week-

temperance journal, and of the "Hydro-athic Review," a quarterly magazine. He has also edited since 1845 the "Water-Cure Journal," and for a portion of the time "Life Illustrated," a weekly newspaper; Smith's "Fruits and Farinacea;" Hardell's "Hydro-athy for the People;" and Smee's "Accidents and Emergencies." His own works are: "Prize Essay on Temperance;" "Hydro-athic Encyclopædia" (New York, 1852); "Hydro-athic Cook Book" (1854); "Uterine Diseases and Displacements" (1855); "Home Treatment for Sexual Abuses;" "The Alcoholic Controversy;" "The Complete Gymnasium" (1857); "Prize Essay on Tobacco;" "Diseases of the Throat and Lungs;" "Pathology of the Reproductive Organs;" "Diphtheria;" "The Scientific Basis of Vegetarianism;" "Water Cure for the Million;" "Nervous Debility;" "Lecture on Drug Medicines;" "Lectures on Diseases of Females;" and "Principles of Hygieio-Therapy." He was nearly ready for the press a large work entitled "Principles of Hygienic Medication."

TRAM ROAD. See RAILROAD.

TRANÇE. See CATALEPSY.

TRANQUEBAR, a town and district of British India, in the province of Tanjore and Madras presidency, on an island formed at the mouth of the river Cavery, 147 m. S. from Madras; area of the district, 15 sq. m.; pop. in 1814, 23,426, since which it has considerably increased. There are two Lutheran churches, a Roman Catholic chapel, and several schools. Tranquebar has some manufactures of cotton cloth, oil, soap, &c. It formerly belonged to the Danes, but was ceded to the British in 1845.

TRANSCENDENTAL (Lat. *transcendo*, to go beyond), in metaphysics, a term applied in general to ideas and doctrines that are not suggested or limited by experience. In the scholastic philosophy, *transcendens* and *transcendentalis* designated any thing that was not *prædicamentalis*, that is, any thing that rose above, was not comprehended in, and could not be defined by, either of the ten *summa genera* or categories of Aristotle. Thus, being was transcendental, and only some category of being was *prædicamentalis*. The four scholastic transcendentials were *ens*, *unum*, *verum*, and *bonum* (being, unity, truth, and goodness), to which some added *aliquid* and *res*, which however scarcely differed in meaning from *ens*. Kant gave new and distinct significations to *transcendens* and *transcendentalis*. The former designated what is wholly beyond experience, as conceivable neither *a priori* nor *a posteriori*, and thus lies beyond every category of thought. The latter designated *a priori* conceptions and judgments, which are necessary and universal, and which transcend the sphere, while affording the conditions, of the contingent knowledge furnished by experience. Thus by the transcendental, formal, or critical philosophy of Kant is meant his system of the principles of the pure reason, which occupies itself not

with the objects or matter of knowledge, but with the subjective ideas or forms, as time, space, substance, and causality, through which objects are represented to us as phenomena. Objects in themselves (*Dinge an sich*) he deemed transcendent.—In mathematics, transcendental quantities are those which cannot be expressed by a finite number of algebraic terms, but are represented by means either of logarithms, or variable exponents, or some of the trigonometrical functions. Transcendental curves, as the logarithmic spiral, are those whose equation is transcendental, *i. e.*, expresses a relation between transcendental quantities.

TRANSFUSION OF BLOOD, the transferring of blood fresh, or by an interval of time so short as to forbid its cooling or coagulation, from the system of one brute or human being to that of another, or from the vessels of brutes to those of the human subject. The rise or revival of this operation in the 17th century seems to have been instigated by curiosity, or a disposition to inquire into the powers of the animal economy. At this period, Mr. T. Clarke, in England (1657), first performed transfusion upon dogs, but unsuccessfully ("Philosophical Transactions," No. 35); Lower in 1665 succeeded in case of the same animals; and with these and other creatures, as pigeons, and even in transfer of the blood of sheep to dogs, the experiment was many times repeated without apparent injury, within the course of a few years. But while France and England have contested the honor of originating the practice at the period named, Libavius had in 1615 distinctly described the operation in case of the human subject, and had indicated the purpose of renewing vitality, which had been sought from it at a later period; and even a passage in Ovid has been supposed to allude to the process of transfusion. The experiments of Lower and others referred to seem to have revived the most chimerical anticipations of possible benefit from the practice. The first trial on man was by Denys and Emmerez, in Paris, in 1666. Though the accounts are somewhat conflicting, it appears that this experiment was in transfusing several ounces of the blood of a sheep into the veins of a demented youth; and although it was asserted that the intelligence of the subject improved after the operation, yet soon after a second transfusion, which was public, as the first had been, he died in a lethargic condition. The next year Lower and King transferred about 10 ounces of the blood of a sheep into the veins of a literary man, Arthur Ooyn, who in ordinary health offered himself for the experiment; no ill consequences ensued at this time; but though on a second transfusion in this case the results were less favorable, the royal society still recommended perseverance in these attempts. In 1688 Riva and Manfredi performed a like operation in Italy. Other unfavorable accidents from the process occurred about this time. Denys and Emmerez having transferred the blood of a calf into the veins of

a youth of distinction, Baron Bond, of Sweden, then in Paris, who had intestinal disease, and died of inflammation excited in the parts after the second operation, the parliament of Paris interfered and proscribed the practice; and upon the death of two persons in Rome from the like treatment, the pope also issued a prohibitory edict. From this time the practice fell into disuse, save as a matter of experiment in case of the lower animals. In 1785 Dr. Harwood, professor of anatomy at Cambridge, strove to revive the inquiry; he bled a dog until it apparently expired in convulsions, when, upon replenishing the animal's veins with blood from a sheep, it revived, and being released went home with no apparent injury. To Dr. Blundell, however, and probably about the year 1800, is due the credit of first giving to the process its true and only useful application. Among his striking experiments were those of reviving with the blood of a dog another that had been apparently dead for 5 minutes; and nourishing a dog 8 weeks without food, by mere transfer in that interval, into the external jugular vein, of 84 oz. of blood from other dogs. But Prévost and Dumas, reasoning from the many differences of blood of different animals, not only known but unknowable also, had inferred that transfusion between different species could never be really harmless; and in their experiments, they found that this especially was true when the corpuscles, though of the same form, were of quite unlike size; but still more so when blood with circular corpuscles was introduced into animals in which these bodies have the oval form; so that, if the blood of quadrupeds be introduced into the veins of birds, the latter speedily die as if poisoned, and with violent distress of the nervous system. These results Blundell reaffirmed; and the application which he made of the practice was, as a means of recovery, by transfusion of human blood, in persons threatened with imminent death from excessive hæmorrhages, as under surgical operations, or in some of the accidents of parturition; and in those cases in which, even if death did not threaten at once to result, the extreme loss and prostration must in the judgment of the practitioner be followed only by more lingering dissolution of days or weeks, with the incidental debility, dyspepsia, diarrhoea, and nervous maladies. His instruments for the purpose were an impellor (syringe with needful tubes) and gravitator; they have since been improved by Weiss, Laundry, and others.—The instruments when used should be perfectly clean, air-tight, and warmed to the temperature of the blood. Opening a vein of the patient's arm just sufficiently to admit the small end of one tube, and fixing the opening by a probe, blood must be drawn through a free opening in the vein of some healthy person, and, as it flows into the appropriate basin, is to be slowly sucked up, and without any admixture of air, by the syringe through the other tube. The syringe and tubes being entirely filled until blood flows

clear from air from the end of the tube to be introduced, this is inserted into the patient's vein, and a steady and slow injection performed, the greatest care being required that neither air nor clots shall be thrown in, and that the charge shall not be so sudden as to occasion shock or congestion or to overpower the heart, the action of which is necessarily enfeebled. Hence, if headache, flushing of the face, fainting, or other unpleasant symptoms occur, after the injection of 2 or 3 oz., the operation should be suspended for a few moments; otherwise, it is to be continued until some good effect is perceived, though usually 4 or 5 oz. suffice for this, and the quantity should never exceed from $\frac{1}{2}$ to 1 pint. A second or even third injection, after the lapse of some little time, may be advisable. Since the remedy is one attended with some hazard, it should not be resorted to until all others have failed or obviously must fail; but when this point is reached, and the operation is decided upon, no delay should occur. In certain cases, the shock and exhaustion of the brain or heart cannot be overcome, and death takes place in spite of the operation; if the last agony has actually commenced, transfusion must be unavailing; and the futile anticipation of renewing and prolonging the life of persons sinking under ordinary disease or of old age, by introducing into their veins the blood of the young and vigorous, is no longer entertained. But in cases such as those already indicated, the operation has now been frequently resorted to with benefit.

TRANSIT, in astronomy, the passage of a planet across the disk of the sun, or of a satellite across the disk of its primary; also, the passage of a heavenly body across the meridian of the place of observation, sometimes called its culmination. Of the planets, only Mercury and Venus, having orbits within the orbit of the earth, can present this phenomenon. The transits of Venus are of great importance, being employed for no less an object than the determination of the sun's distance; they recur at alternate intervals of 8 and 105½, and 8 and 121½ years. The earliest transit of the sun's disk of which we have an account is that of Venus in 1639, predicted and observed by Jeremiah Horrox, an amateur astronomer of Lancashire, England. The last occurred in 1769, and was observed with great care in opposite quarters of the earth, expeditions having been equipped for that purpose by several European sovereigns; the solar parallax as now received was then determined. The next will occur Dec. 8, 1874, and is looked forward to with great interest for verifying these determinations. The transits of Mercury are much more frequent than those of Venus, in consequence of the former planet being nearer the sun, and having thus a narrower orbit and a shorter year; but they are not available for the determination of the solar parallax. The transit of stars is employed in the determination of longitude. (See LONGITUDE.) The pre-

cise relative situation of the heavenly bodies in respect to their right ascension is determined by comparing together their exact times of transit; these times are ascertained by means of an instrument known as the transit.

TRANSIT CIRCLE, an astronomical instrument used for determining the absolute positions of the heavenly bodies. As these positions are given by two independent elements, the right ascension and declination, corresponding to geographical longitude and latitude, so this instrument is a combination of two independent constructions, each giving its share to the name of the whole, and each furnishing its corresponding element by independent and yet simultaneous observation. The transit circle now forms an essential part of the equipment of every well constituted observatory; upon the perfection of its details the mechanical artist and the mechanical astronomer have lavished their best efforts; and for the symmetry and harmony of its arrangements, no less than for the exquisite delicacy of its mechanism, it may fairly be considered the masterwork of modern instrumental astronomy. The two constructions which have here combined their powers are the transit instrument and the meridian or vertical circle. The former consists of a telescope whose tube is composed of two slightly conical portions firmly secured at their bases to opposite sides of a hollow central cube, from two other opposite sides of which proceed also equal cones of more massive make, generally indeed cast in the same piece with the cube, and forming an axis at right angles with the telescope. At or near the extremities of this axis are two perfectly cylindrical, highly finished pivots of hardened steel, corresponding in position to sockets resting upon stone columns which, based firmly in the ground, exactly east and west of each other, and rising to a convenient height, support the instrument so that the telescope revolves freely between them in the plane of the meridian. This gives the simple transit instrument, by which and its necessary accompaniment, the clock, is observed the time of meridian passage—the transit—of the star whose place is to be determined. If now we attach firmly to the axis a finely graduated circle which will revolve with the telescope, we shall be enabled, by means of its divisions, to measure also the precise altitude of the star at the same instant of culmination; and thus the transit circle will give, by the first observation, the desired right ascension, and by the second, the desired declination of the object. This combination is entirely of modern date. Transit instruments and meridian arcs and circles have been used ever since the days of Roemer and Picard, but the first real conjunction of the two dates from the close of the first quarter of the present century.—In considering the mechanism of the transit circle, we will first notice the sockets which receive the pivots and determine the position of the instrument. These sockets are not formed, as

might be supposed, of circular “boxes” accurately fitting the pivots, but are simply solid little pieces of gun metal, cut away at the upper surface by two planes inclined to each other like the sides of the letter V, from which letter they take their technical and convenient name. In these V’s the pivots revolve smoothly and truly, touching the inclined sides at but two points, and consequently without the lateral play which it would be impossible to avoid in circular boxes, however truly ground. Again, the stone piers upon which the instrument rests, even though wrought into perfect symmetry and equality in every respect, and though posited in such a manner as to furnish no apprehension of relative change, will yet continually manifest such change, sometimes under the influence of varying temperature from day to night and night to day, but more frequently from causes even more irregular and less known than this. In order therefore to be able to keep the axis of the instrument duly east and west and truly horizontal, the V’s are not permanently bedded in the stone, but are so held by strong plates of the same material, themselves permanently fastened, as to allow of small changes of position, one in a horizontal and the other in a vertical direction. Passing next to the telescope, we notice that the narrower ends of the tapering tubes are terminated by flat rings of precisely the same dimensions, upon which are fitted caps containing, one the object glass and the other the eye tube with its mechanisms. These caps are of exactly equal weight, and, partially entering the ends of the tube, their centres of gravity fall truly in the line of junction with the telescope. Thus the instrument is not only perfectly counterpoised, but also, the caps being convertible, the object glass and eye tube may be and should be periodically interchanged, in order to eliminate from an average result the effect of a possible flexure of the tube. The object glass presents nothing worthy of especial remark, its office being simply, as in every other telescope, to furnish to the observer a perfectly sharp and well defined image of the star, admitting of vision equally distinct, and, so to speak, tangible, with that of the threads in the field of view. The construction of the eye piece is peculiar to this instrument. The term “eye piece” is generally, though incorrectly, applied to the whole mechanism at the eye end of the telescope, which consists of a small tube sliding in the end cap, and carrying not only the eye piece proper, which is of the form known as Ramsden’s (see TELESCOPE), but also a conveniently shaped box containing two thin metallic plates. These plates, called diaphragms, are made with central openings, across which are stretched the threads used to mark the star’s position in or its progress through the field. One of these diaphragms is used for the observation of transits, and is securely held in place by fine “antagonist” adjusting screws. Across its opening and pre-

closely through the centre of the field is stretched vertically a most delicate thread of spider's web, which, as the instrument revolves, represents to the observer's eye the meridian as a visible line across which the heavenly bodies are seen to pass at the moment of culmination. In order, however, to gain more accuracy in this observation (for the instant of transit is required to be known within a small fraction of a second), other threads are also introduced parallel with the central one and symmetrically disposed on either side of it, so that, by noting the time of crossing each and taking the average, a very great degree of certainty is attained. Ordinarily the transit diaphragm contains either 5 or 7 threads, all at equal intervals; but for special purposes their number and arrangement are adapted to the circumstances. With a telegraphic method of registry, as practised with the large transit instrument of the Washington observatory, 5 different sets or tallies, with 5 threads in each, are sometimes used. Across the same diaphragm is stretched horizontally another fixed thread, as a guide to the observer in placing the telescope so that the star shall traverse the centre of the field. The second diaphragm, carrying only a single horizontal thread, is movable in a vertical direction between truly fitting guides, and by means of a finely wrought micrometer screw. As the first plate belongs to the transit portion of the two-fold construction, so this one belongs to and coöperates with the circle, and the office of the screw which carries it is to measure the exact distance of the star, as it traverses the field, either from the fixed horizontal thread, or from some other definite starting point, which may be represented upon the scale of the screw without being necessarily visible. Attached to the screw and revolving with it is a small disk or "head," whose edge is divided into 100 equal parts, so as to measure very accurately the fractions of a revolution, while the whole number of turns necessary to carry the thread to any part of the field is registered upon a convenient scale usually placed within the eye piece and visible with the threads themselves. In order to render thread and scale visible by night, various contrivances are used, the most common of which is to introduce a flat oval ring with whitened surface into the central cube, and with its plane inclined at an angle of 45° with the axis, so that, receiving light thrown in through an orifice in the pivots, it will reflect sufficient into the field to show the threads as black lines upon a bright ground. Sometimes also the illumination is thrown upon the threads themselves when they appear as bright lines upon a dark ground; and in the great transit circle at Greenwich a very ingenious combination of prisms enables the observer to produce either effect at pleasure.—Upon each half of the axis, between the cube and the pivots, is a circle whose diameter is usually from one third to one half the length of the telescope. These circles with their several radii and cross bars

are generally cast each in a single piece, to insure greater firmness and avoid unequal tensions. But the 6-foot circles of the Greenwich instrument just mentioned, weighing about 300 pounds each, are made of two castings, the rim in one, and the whole system of radii and braces in another, the two being afterward firmly bolted together at 12 equidistant points. Upon a narrow band of silver inserted near the circumference of the circles are cut the graduations required for the special office of each; one, used only for pointing the telescope in any given direction, is divided so as to read with a vernier to single minutes, which is abundantly sufficient for the purpose; the other circle, intended for the exact measurement of angles, is divided with the most scrupulous accuracy into arcs of 2, 3, or 5 minutes, as the case may be, and, once fixed upon the axis, should never during observations be handled or subjected to unequal pressure or strain of any sort. Assuming now that these division marks are truly cut, we next look for the means of subdividing the small arcs into seconds and fractions of seconds, and find this accomplished by a system of "reading microscopes." These are microscopes of the ordinary compound construction, but each provided with a micrometer screw carrying, as in the German instruments, a pair of close parallel threads between which the image of the division under consideration can be placed with great accuracy, or, as in Troughton's form, two threads crossing each other at a very acute angle, which may be bisected by the division. The microscopes are so made that one revolution of the screw is equal to a minute, and the micrometer head is divided into 60 equal parts, each of which therefore represents a second. There are usually 4 of these microscopes placed 90 degrees apart; but sometimes as many as 6 are used for the purpose of attaining still greater certainty in the result, both from the greater number of readings and from the probable reduction of the systematic errors of the primary division. The proper method of supporting these microscopes in order to insure their perfect stability has been always a subject of much study. A favorite plan has been to place them on the periphery of another smaller circle which rests, accurately fitting, upon the axis itself, but is prevented from revolving with it by a small projecting bar caught below between two screws attached to the pier. Of late years, however, experience seems to have decided in favor of securing firmly and independently upon the pier itself, near the V-plate, a solid block of metal which serves as the centre of a strong square frame at whose corners the microscopes are attached by suitable adjusting screws. The microscopes are thus entirely disconnected from the circle; and although every new adjustment of the axis will show itself in their record of the graduations, yet this produces no effect whatever upon the mean of readings of opposite microscopes. In the Greenwich instru-

ment, whose piers are broader than the circles themselves, the microscopes are very long, and are passed through the pier itself, converging from the rim of the circle until their eye pieces are collected within a very small space, where the observer reads them with convenience and ease. The graduated limb is bevelled to suit this arrangement, and from another point near the observer a small gas-burner radiates light through other openings in the pier in such a manner as to illuminate uniformly the field of each microscope—a matter of very high practical importance.—With this brief sketch of the construction of the transit circle, we will now consider its use, commencing with the speciality of the transit instrument by showing how it is brought into its proper place in the meridian. It is necessary that the middle vertical thread of the fixed diaphragm be placed truly in the optical axis of the telescope, which is the central line of the cone of rays converging from the object glass. This may be effected by turning the telescope to a very distant fixed object, noting the exact position of this middle thread with reference to the images in the field and then reversing the instrument, when the thread will probably occupy a different position, whereupon it must be brought by the adjusting screws of the diaphragm to a point midway between the first and second places, and the operation repeated until no change appears upon reversal. Next, by means of a spirit level and the vertical adjusting screws of one of the V-plates, the axis of the instrument is rendered truly horizontal; and finally, the approximate sidereal time being known, the telescope is directed to some star, also known, very near the pole of the heavens, and the axis moved by the horizontal adjusting screws of the other V-plate, until at the right moment the star and thread coincide exactly. The three errors thus corrected are denominated the errors in collimation, level, and azimuth respectively. And now, having done our best mechanically to put the instrument right, we turn around, and, by help of stellar observations under properly varied circumstances, are able not only to determine with great precision the small outstanding values of these errors, which by no means remain constant for any length of time, but also to judge the clock that aided us, and finally the very places of the stars that have served as our guides. The errors of instrument and clock having been thus determined, it is possible, by the aid of formulas and methods which have been so thoroughly developed and systematized as to be applicable with the greatest facility, to obtain by a single observation of any new object its right ascension within a very small fraction of a second of time.—But, as we have intimated, the chief value of the instrument consists in its power of furnishing at the same culmination not only the right ascension but also the declination of the object, and it accomplishes the latter most simply in the following manner.

While the observer is noting the progress of the star across the transit threads, he at the same time, by a delicate movement of the telescope in altitude, places it so that the star appears to run along the fixed horizontal thread; and then, the transit observation having been completed, he reads, even to the fraction of a second, from the circle microscopes the precise point corresponding to the apparent altitude of the star. Or, a still more accurate determination is obtained by placing the telescope so that the star will traverse the field at a little distance above or below the fixed thread, and there is ordinarily time enough to bring the movable thread several times into coincidence with the star's image by means of the micrometer screw, always noting its indications and afterward taking the mean of all. The small distance from the fixed thread, as thus measured, must of course be duly applied as a correction to the readings of the microscopes, and thus we derive one extremity of the desired arc, and then proceed to find the other. In order to know the star's declination, we must first have its altitude above the horizon. This can sometimes be obtained by a double observation of the star's image, first as reflected from a quicksilver surface, and then as seen directly, in which case the arc included between these two directions is obviously equal to twice the altitude of the star; but this course is not always applicable. We have however a readier and exquisitely beautiful method of obtaining with very great accuracy the direction of the vertical line, from which we can count the star's zenith distance. The telescope being turned so as to look directly downward, we place immediately beneath it a vessel of quicksilver; and if then, by means of a small plate of thin glass held at an angle of 45°, we reflect a strong light down the telescope, it will be reflected back by the quicksilver, and, looking through the glass from above, we shall see not only the threads in the eye piece, but also the reflected image of each; and by moving the instrument carefully until the fixed horizontal thread coincides with its own image, we shall have the telescope mathematically vertical, and may read from the circle the corresponding second point of the desired arc, whereby we obtain the apparent altitude, and thence, correcting for refraction, the true altitude, and finally the desired declination.

TRANSYLVANIA (Hun. *Erdély*; Ger. *Siebenbürgen*), a grand duchy of Austria, forming the S. E. province of the empire, bounded W. and N. by Hungary, N. E. and E. by the Bukovina and Moldavia, S. by Wallachia, and S. W.

by the Military Frontier; area, according to the last changes of the frontiers, 21,197 sq. m.; pop. in 1857, 1,926,727. Capital, Klausenburg. The province is surrounded on all sides by mountains belonging to the Carpathian system, and the surface is much diversified, being traversed by several mountain ranges, between which there are numerous fine valleys and plains. The principal chain extends along the E. and S. frontiers, and sends out many offsets, the most important of which runs in an E. and W. direction and forms the watershed of the country. The range which forms the N. W. boundary toward Hungary is properly designated as Transylvanian Ore mountains. The most elevated points lie near the S. or Wallachian boundary, in the so-called Transylvanian Alps, where Mt. Negoi has a height of more than 8,000 feet above the sea, and Mt. Butechetich is very little lower. The Roman, Red Tower, Vulcan, and Iron Gate passes lead through this range. The whole drainage belongs to the basin of the Danube, the chief rivers being the Aluta (Hun. *Olt*), the Maros with its tributaries the Great and Little Kokel (*Küküllö*), the Bistritz (*Beszerese*), the Szamos, and Körös. There are several lakes and marshes.—The climate varies greatly according to elevation. In the valleys the heat of summer is very great, but in the more elevated districts the winter temperature is remarkably severe and so long continued as to cause serious injury to vegetation. Gold is found in most of the streams in greater or less quantities; and 22 gold mines are worked and are said to be very productive. Silver mines are also worked, and there is one of quicksilver. Copper, lead, iron, antimony, arsenic, tin, coal, alum, bitumen, saltpetre, and salt are all found; together with crystals and valuable pebbles, including garnets, chrysolites, amethysts, chalcedonies, agates, carnelians, and jaspers. A bed of rock salt extends in a belt 60 to 80 m. wide through the whole country, from which great quantities are extracted, as well as from numerous springs. In the more elevated parts vegetation is scanty, but lower down luxuriant forests make their appearance, which yield many kinds of valuable timber. The valleys and plains are particularly fertile, and, although agriculture is in a backward state, yield good crops of various kinds of grain, pulse, maize, hemp, flax, tobacco, saffron, and madder; and the vine and fruits are very generally cultivated. Great numbers of horses, horned cattle, buffaloes, sheep, and pigs are reared, large herds of the last named being fed in the forests. Game is abundant, and the rivers are well supplied with fish. The manufactures consist principally of coarse linen and woollen goods, native silk, different kinds of metals, paper, gunpowder, leather, porcelain and earthenware, glass, stearine candles, soap, furniture, and numerous articles in wood. The exports consist of salt, grain, cattle, wax and honey, tobacco, timber, wood, metals, an-

timony, hides, and wool; and the imports of various manufactured goods, but more particularly of colonial produce, glass, tissues, and millinery. The transit and commission trade is entirely in the hands of Greeks and Armenians.—The population is composed of various races, including Magyars or Hungarians proper, Szeklers, Saxons, Wallachs, Ruthenians, gypsies, Armenians, Greeks, Jews, and Bulgarians. The Wallachs are by far the most numerous, being about one half of the whole. The gypsies number about 60,000. The religions most numerous are the united and non-united Greek (chiefly by the Ruthenians and Wallachs), Calvinist (by the Magyars), Lutheran (by the Saxons), and Unitarian (by the Szeklers). The Magyars and Saxons have the best schools, and those belonging to some of the others are of a very inferior character. The Szeklers, or properly Székelys, who are believed by some to be descendants of the Huns, and by others of the Petcheneges and other tribes kindred to the Magyars, use a dialect little different from the language of the latter, this being also spoken by the Bulgarians and Armenians. The Saxons, descendants of German settlers from Flanders, the lower Rhine, the Hartz, and Thuringia, who established themselves in Transylvania especially in the 2d half of the 12th century, where they are unmixed with other races, speak their own language, the German, with a considerable degree of purity. They enjoy various privileges, based chiefly on a charter granted them by King Andrew II. in 1224, and more equality of rights than the other races. Together with the Magyars and Szeklers they form the constitutionally ruling people. The country is therefore divided into the lands of the Hungarians (chiefly in the N. E.), of the Szeklers (in the E.), and of the Saxons (in the S. and N. E.). The land of the Hungarians is subdivided into the counties or *comitatus* (*megyék*) of Klausenburg (*Kolozs*), Inner Szabolc, Doboka, Thorda, Kokelburg (*Küküllö*), Upper Weissenburg (*Féjérvár*), Lower Weissenburg, and Hunyad, and the districts of Fogaras and Nászod; the land of the Szeklers into the seats (*Székek*) of Aranyos, Maros, Udvarhely, Csik, and Három-Szék; and the land of the Saxons into the seats (*Stühle*) of Hermannstadt, Broos, Mühlenbach, Reissmarkt, Mediasch, Schissburg, Gross-Schenk, Leeschkirch, and Repe, and the districts of Kronstadt and Bistritz. Beside the capital, the most important towns are Hermannstadt, Kronstadt, Vasarhely-on-the-Maros, Bistritz, and the fortress Carlsburg (*Károly-Féjérvár*). The constitution of Transylvania, before the revolution of 1848-'9, during which it was reunited with Hungary, resembled that of the latter country, but was more complicated, owing to numerous reserved privileges. It was abolished by the Austrians in 1849, and restored in 1861, though not in its full vigor.—Transylvania in the time of the Roman empire belonged to Dacia, was subsequently overrun by

the Huns, Goths, Gepidae, Lombards, Bulgarians, Avars, Petcheneges, and other tribes, and at the close of the 10th century conquered by the Hungarians, who ruled it by waywodes, for a time disputing its possession with the Cumans. Having shared the fate of Hungary for centuries, it became an independent principality during the Turkish-Austrian wars, being ruled among others by the Zápolyas, Bathoris, Bocskay, Bethlen, the Rákóczy, and Apafis, until it was finally annexed to Austria in 1713. (See HUNGARY.) Among the most important recent diets of Transylvania were those opened in 1834, 1842, and 1848. On the E. and S. frontiers the people down to a late date held their land under the tenure of protecting the country against foreign aggression in these directions, the hardy and warlike Szeklers in the E. constituting the principal strength of this military frontier organization.

TRANSYLVANIA UNIVERSITY. See LEXINGTON.

TRAP (Swed. *trappa*, a stair), a class of rocks so named from the stair-like or columnar structure of its masses. The traps are distinguished by their composition, which consists chiefly of feldspar, augite, and hornblende, in various proportions and states of aggregation. Among the principal varieties are the basalts, amygdaloids, greenstones, dolerites, &c.

TRAPANI, a province of Sicily, situated at the W. extremity of the island, bounded E. by the provinces of Palermo and Girgenti, and on the other sides by the Mediterranean sea; area, 1,387 sq. m.; pop. in 1859, 205,566. The coast line is very irregular, and there are several bays, the largest of which is the gulf of Castellamare. The most important of the numerous islands off the W. coast are the three anciently called the *Ægates Insulæ*, viz., Favignana, Levanzo, and Maretimo. The surface of Trapani is traversed by several offsets from the Madonian mountains, which have their W. extremity in this province. Many rivers and streams take their rise in these hills, but their courses are all short, and none of them are navigable. The soil is generally fertile, and produces abundant crops of grain.—TRAPANI (anc. *Drepanum*), the capital, is situated on a peninsula which extends into the Mediterranean, 16 m. N. N. E. from Marsala (anc. *Lilybæum*), and 46 m. W. S. W. from Palermo; pop. in 1856, 27,286. It is surrounded by walls and defended by several outworks. The streets are regular, but generally badly paved, and many of the houses are well built. There is a cathedral, about 40 churches, a palace where the provincial assemblies hold their meetings, a college, 2 seminaries, 2 hospitals, and some charitable institutions.—*Drepanum* (Gr. *δρεπαν*, a sickle, from the shape of the promontory) was founded by Hamilcar during the first Punic war, about 260 B. C., who transferred thither the inhabitants of the neighboring city of Eryx. It remained one of the chief strongholds of the Carthaginians throughout the

war; off its port they gained a great naval victory under Adherbal in 249, destroying nearly the whole Roman fleet; and it was in attempting to raise its siege by the Roman consul Catulus in 241, that their ships under Hanno suffered, off the island of Favignana (anc. *Ægusa*), the total defeat which ended the war. Its name does not again appear in ancient history.

TRAPEZIUM AND TRAPEZOID (Gr. *τραπεζία*, a table). In geometry, the first of these terms is a general name for a plane figure bounded by four straight lines, no two of which are parallel; the other is restricted to such a figure having two opposite sides parallel, differing in this respect from a parallelogram, in which each pair of opposite sides is respectively parallel.

TRAPPISTS, the name of the most rigorous among the religious orders of the Roman Catholic church, founded by the abbé de Rancé in the celebrated abbey of La Trappe, in the department of Orne. This abbey was founded about 1140 by the liberality of a count of Perche, and adopted the rule of the Cistercians in 1148, but subsequently so much degenerated that its inhabitants came to be called "the bandits of La Trappe." Rancé received the abbey as a benefice when only 12 years of age, and, having entered the order after a dissolute life, not only reformed its morals, but laid in it the foundation of a new and independent branch of the Cistercian order (1666), called, after the name of the abbey, the Trappists. (See RANCÉ.) The monastic rule is noted for its severity. The members rise in the morning at 2 o'clock, and 12 hours a day are devoted to devotional exercises, the remainder to hard labor, mostly in the field. No worldly conversation is allowed; when meeting, they salute each other with the solemn *Memento mori* ("Remember death"). Their scanty food consists of water and vegetables; meat, wine, and beer are entirely forbidden. They sleep on a board, with a pillow of straw; and they never undress, not even in case of sickness. Hospitality is earnestly recommended; but it is also enjoined to the members to observe, in the exercise of hospitality, as much as possible the customary silence of the order and the simplicity of its mode of life. Until the time of the French revolution the order of the Trappists spread but little, remaining confined to the abbey of La Trappe, one establishment in Tuscany, and one in western Germany. The revolution expelled them from La Trappe in 1791, and for more than 20 years the scattered members wandered through Switzerland, Germany, England, Spain, Russia, and North America, founding from time to time a number of new establishments, most of which they were after a few years again compelled to leave. In 1817 they returned to La Trappe, and soon founded a number of other establishments in France. The order was especially prosperous under the administration of the superior-general Geramb (after 1825), one of the few Trappists who have won a reputation

for authorship. In 1828, and again in 1830, all the French establishments of the order were ordered by the government to be suppressed, but in neither case was the decree executed. In 1860 they had 15 abbeys in France, and a large establishment at Staoueli in Algeria, which receives an annual stipend from the government, and sustains a large agricultural school for young Arabs; there were also in the same year 3 houses in Belgium, 2 in Italy, 1 in Ireland, 1 in Turkey, and 3 in North America (New Haven in the diocese of Louisville, New Melleray in the diocese of Dubuque, and Tracadie in the diocese of Arichat, Canada); in all, 26 abbeys with about 2,000 members.—An offshoot of the order of Trappists is the congregation of "Trappist Preachers," founded about 20 years ago by the abbé Murard, at Avallon, France, which connects home missionary labors with the observance of a Trappist mode of life.—The first convent of Trappist nuns was founded in 1692 in France. In 1860 they had altogether 8 houses, of which one was in England (Stapehill in Dorsetshire), and the remainder in France.

TRAVANCORE, a semi-independent native state of Hindostan, subsidiary to the Madras presidency, occupying the S. W. extremity of the Indian peninsula, bounded N. by Cochin and Coimbatore, E. by the Ghauts, which separate it from the British districts of Tinnevely and Madura, and S. and W. by the Indian ocean; area, 722 sq. m.; pop. 1,011,824. The capital is Trivandrum; other chief towns, Quilon, Alleppey, Anjenga, and Kotar. The N. part of the coast is low and sandy, and bordered with extensive groves of cocoanut trees; but toward the S. extremity, which terminates in Cape Comorin, it assumes a bolder aspect. There is no harbor, but the roadstead of Alleppey is one of the best upon the Malabar coast. Travancore is well watered by several rivers, those of the N. part of the country flowing into "backwaters" or lagoons, which extend for a considerable distance nearly parallel with the coast. The mountains which form the E. boundary vary in height from 4,000 to 7,000 feet; and the tract lying between them and the coast is generally hilly till it approaches the neighborhood of the sea. During the S. W. monsoon, between June and September, heavy rains fall and cool the atmosphere; but at other seasons the climate is dry, and in the months of February, March, April, and May the weather is exceedingly hot. Pepper, cardamoms, ginger, cocoa and areca nuts, cinnamon, nutmegs, and rice are all cultivated; the last named yields two or three crops in the year. The wild animals resemble those of the province of Malabar. The horned cattle of Travancore are all small, and horses are not much used. There are but few manufactures; a little sugar is made, and some salt. The exports consist principally of pepper, ginger, various spices, dye stuffs, areca and cocoa nuts, timber, and dried fish.—Travancore is a portion of ancient Malabar, and the inhabitants and

customs are similar to those found in that province. The rajah is a Hindoo; and the inheritance of the sovereignty, as well as that of all property, passes in the female line. The population includes about 170,000 Roman Catholic and Syrian Christians, and about half that number of Moplahs. Toward the middle of the last century the rajah of Travancore extended his territories to their present limits, but in 1790 he was obliged to call upon the British to assist him in preserving his dominions from the grasp of Tippoo Sultan; and by subsequent treaties he yielded up a good part of his sovereignty, and agreed to pay a large subsidy, in consideration of British protection.

TRAVERS, JULIEN GILLES, a French poet and miscellaneous author, born in Valognes, department of Manche, Jan. 31, 1802. After teaching in several provincial colleges, he became in 1832 principal of the college of Falaise. From 1842 to 1856 he occupied the chair of Latin literature at Caen. Beside several volumes of original poems, including *La Algériennes* (1827), *Les distiques de Muret*, imitated in French verse (1834), *Deuil* (1837), and *Gerbes glanées* (1859), he has published an edition of the poetical works of Boileau, the *Vaux-de-Vire* of Oliver Basselin (1839), and a translation of the "Phoenix" of Cardinal Bona (1858); and he has edited since 1829 the *Annuaire de la Manche*, a valuable repertory of local history and statistics, and since 1840 the *Bulletin de l'instruction publique et des sociétés savantes de l'académie de Caen*, of which he became secretary in 1839.

TRAVIS, a central co. of Texas, intersected by the Colorado river; area, about 1,000 sq. m.; pop. in 1860, 8,080, of whom 3,186 were slaves. The surface is moderately hilly, and the soil very fertile. The productions in 1850 were 149,865 bushels of Indian corn, 18,637 of sweet potatoes, 41,102 lbs. of butter, and 234 bales of cotton. There were 2 newspapers and 188 pupils attending public schools. Steamboats ascend the river to Austin, the capital of the county and of the state.

TREADMILL, or TREADWHEEL, an instrument of punishment, formerly extensively adopted in England and the United States, but now generally abandoned, from its injurious and depressing effect. The treadmill was similar in construction to an ordinary water wheel, only that the buckets of the latter were replaced by stepping boards or planks, on which there was room for 10 to 20 men to stand in a line, the weight of whose bodies caused the wheel to revolve, and thus compelled them to step constantly from one stepping board to the next above it. A hand rail was provided, by taking hold of which the prisoner was prevented from being drawn down by the revolutions of the wheel, and a screen of boards above prevented his climbing it. The wheel was used for driving machinery. The rate of exertion maintained by the convicts depended upon the height of the steps and the velocity of the rev-

inventions; the former varied from 7 to 9 inches, and the latter required an average of 45 steps per minute. To maintain this velocity, relays of men were necessary, as one gang could not continue the exertion more than 10 or 12 minutes at a time. After resting 5 or 6 minutes, they were able to resume their labor. The hours of labor were usually 10 per day, and a prisoner would be on the wheel about 6½ hours in that time. The number of feet of ascent per day ranged from 8,000 to 21,000.—The treadmill was introduced into England, in the bridewell at Bury, by William Cubitt, in 1818, and for some years was employed in most of the county prisons. In Coldbath-Fields prison females were put upon the wheel, but it was found to produce such injurious effects on their health, that it was after a time discontinued. It was introduced into the United States in 1823, and was first used in New York.—A similar contrivance was the crank machine, by which the prisoner was required to turn a crank to raise water, which was permitted to flow back into the reservoir from which it was drawn; this was adopted in the separate prisons, and a gyrometer out of the reach of the prisoner, but subject to the inspection of the keeper, revealed the number of revolutions made in a day.

TREADWELL, DANIEL, an American inventor, born in Ipswich, Mass., in 1791. While still young he made his first invention, that of a machine for making wood screws. In 1818 he produced a printing press of a new construction, and went to England in 1819. He there conceived the construction of a power press, which on his return was completed in a year, and was the first press by which a sheet was printed on this continent by other than human power. It was widely used; and in New York large editions of the Bible were published by means of it at small cost. In 1822, in connection with Dr. John Ware, he established and conducted the "Boston Journal of Philosophy and the Arts." In 1825 he was employed by the city of Boston to make a survey for the introduction of water. In 1826 he devised a way of conducting railway transportation in both directions upon a single track by means of turnouts, which was the method upon which many of the principal railroads of the United States went into operation. In 1829 he completed a machine for spinning hemp for cordage, which was the first ever successfully used for that purpose; works capable of spinning 1,000 tons in a year were erected in Boston in 1831; and by machines furnished by him in 1836 to the Charlestown navy yard, all the hemp is still spun and the cordage made for the U. S. navy. From that time American cordage began to be exported. The machines were used in Canada, Ireland, and Russia; and one of them, called a circular hackle or lapper, has been generally adopted wherever hemp is spun for coarse cloth. In 1834 he became Rumford professor of technology in Harvard college. Soon after-

ward, perceiving the utility of cannon of a larger caliber than any in use, he devoted himself to that subject, and in four years reduced to practice his method of making cannon of wrought iron and steel. He executed a contract with the United States for 12 6-pounder field pieces, and the government also desired 32-pounders for the navy, and he went to work upon them. But the patronage of the government was not sufficient to warrant a continuance of the manufacture. The great objection to the Treadwell gun was its cost. To obviate this he made an important improvement on his first method of construction, for a description of which see CANNON. He determined by exact calculation, that a gun made in this way would be as strong as if made in his first method, would come within the reach of ordinary skill, and be about as cheap as the common cast iron gun. He described this new method in a memoir before the American academy in 1835, secured his invention by patent, and published an account of it in 1856. It is certain that 18 years before the gun was produced in England known as the Armstrong gun, Treadwell had made his; and that 15 years after his specifications had been published in Europe, and his English patent enrolled, and some years after that patent had been published in the volume of the "English Printed Specifications," Sir William Armstrong produced his gun, formed upon the same plan, and adding thereto rifling and breech-loading. Professor Treadwell believed that it would give us great superiority over all the European powers using the old ordnance, to use guns made in his method, with rifling added, and in 1860 went to Washington to urge this upon the government. In a pamphlet published in 1862 he relates the measures that he adopted, and his ill success. He resigned his professorship in 1845, but still resides in Cambridge.

TREASON, in general terms, any act of hostility against a state, committed by one who owes allegiance to it. There is one important difference in what may be called the form or manifestation of this crime, which seems to constitute a difference in its essence, and has led to some confusion of thought as to the crime itself, and as to the laws or proceedings which have for their end its prevention. This difference is between the crime as it may be committed against a monarch or against a republic. Where the power and majesty of a state are embodied in a personal sovereign, there treason against him is treason against the state; but where the state is not thus impersonated, the treason must be against the state itself, and cannot be committed against any person. The *crimen læsæ majestatis*, in all the ages of republican Rome, was regarded as a crime against the state, and not against its magistrates, excepting as they represented the state. The simple word *majestas* was often used as meaning this offence, although the whole expression of it was: *crimen læsæ, im-*

minuta, diminuta, or minuta majestatis. At a later period, when the emperors, having first accumulated in their persons the higher magistracies of the republic, gradually and yet rapidly became despotic and irresponsible monarchs, while the language of the law remained almost unchanged for a considerable time, the crime itself came to be regarded as primarily a crime against the personal sovereign, and derivatively against the state. In Rome, as afterward in England, the power of the sovereigns to enlarge the scope of this crime, and accuse whom they would of it, was enormously abused. But in both of these countries it always remained, and in all civilized countries it must always remain, the highest of crimes, and more deserving of the severest punishment than any other; and for these reasons it needs to be most carefully limited, and to be guarded not only as to its extent, but as to the proof by which it may be established. The constitution of the United States (art. 3, sec. 3) declares that "treason against the United States shall consist only in levying war against them, or in adhering to their enemies, giving them aid and comfort." This cannot be regarded as a definition of treason, so much as a limitation of it, and a declaration of what portion of the offences which had been at different times included within its meaning should be regarded as so included by our law. The word treason is used as a customary law term of well known significance; and indeed, in the most important cases which have arisen in the United States, it would seem that this provision of the constitution has but exchanged the burden of defining treason, for that of defining the levying war against a state and adhering to its enemies.—In order to show the true meaning of the word treason, we must go back to the Roman civil law, which on this point had an important influence on the English law. In the early days of Rome, the word *perduellio* (from *perduellus*, which is defined by Gaius as *hostis*) was used almost as a synonyme of *majestas*, and indicates the idea of hostility to the state as belonging to it. Although commonly spoken of as the equivalent of treason, *majestas* certainly had a wider extent of meaning and operation than treason ever had in its extremest abuse in England. Cicero says (using the word *majestas* here in its original sense): *Majestas est in imperii atque in nominis populi Romani dignitate.* Elsewhere, for the purpose of defining the criminal offence of *laesa majestatis*, he says: *Majestatem minuire est de dignitate, aut amplitudine, aut potestate populi, aut eorum quibus populus potestatem dedit aliquid derogare;* and in this wide sense, *majestas* was applied to any maladministration in office of any magistrate. It became afterward much more like treason as it was in the worst periods of English history; and the abuse of it may be illustrated by some of the provisions of imperial law about the statues of the emperors. By some of these, it was declared that to repair their statues when going

to decay, or to injure one accidentally and unintentionally, or even sell one if it had not been consecrated, was not a crime against the majesty of the state; but to melt one down after it had been consecrated, constituted this offence. The earliest punishment of the crime was perpetual interdiction from fire and water; the later, death, to persons of low condition by wild beasts or burning, to those of higher rank by the ordinary method of execution.—We find treason recognized and punished as a crime from the beginning of the common law; and always the cause of the crime was some act of hostility against the government by one who owed to it allegiance; in other words, it was the violation of the duty of allegiance. But during many ages the criminal law of England was unwritten, and lay in the determinations of judges who were removable at the king's pleasure, and who were often so corrupt that public justice was perverted into an instrument of remorseless tyranny. In the reign of Edward IV. an unfortunate punster, who kept an inn in London with the sign of the crown, said he would make his son heir of the crown; and for this offence he was hanged, drawn, and quartered. In the same reign an owner of deer, one of which was killed by the king while hunting, said, in a moment of anger, that he wished the horns of the deer were in the king's stomach; and for this he was put to death. But at a later period, when Russell and Sidney were slain through the instrumentality of a judicial trial for treason, this atrocious wickedness assumes at least a more dignified appearance. Indeed, during the whole of English history until the times of Cromwell, treason always had, in a greater or a less degree, the character of a political offence. At many periods the leading men of the age fell victims to it. Hence has arisen a feeling of compassion for the sufferers, and of doubt as to their guilt, which has had an important influence on the public estimation of the crime in that country, and to some extent in this. Another reason for some laxity of thought and feeling concerning this crime, is the extreme uncertainty of the earlier law as to its definition and limits. Thus, Glanville expressly identifies it with the *crimen laese majestatis*; Bracton includes within it the counterfeiting not merely of the king's seal, but of the king's money; and by a very current phrase it was supposed to embrace all "encroaching of (encroachment upon) royal power." So early as the 25th year of Edward III. an attempt was made to remedy this uncertainty by a statute defining treason, which was for the time an excellent law, although quite too wide in its scope. Among the principal offences here called treason were compassing the death of the king, queen, or prince, or levying war against the king, or adhering to the king's enemies; but all these offences were to be proved by some overt act. In some of the subsequent reigns this excellent provision was evaded by con-

struction, or the statute was disregarded, or new ones made. Thus, by the 82d of Henry VIII. it was made high treason to accept, take, judge, or believe the king's marriage with Anne of Cleves as legal and valid. But the leading provisions of the statute of Edward III. are still the law of England, and the reasonable construction of its language by the courts of England has been generally followed by the courts of the United States in construing the provisions of our own constitutions and laws. By the 1st of Edward VI. the provision was introduced which we have copied, requiring, for the conviction of one charged with treason, two sufficient and lawful witnesses; but this provision was in many instances shamefully perverted. Thus when only one living witness could be found who would testify to Algernon Sidney's treason, Jeffreys decided that garbled extracts from his writings might be read as the other witness, and on this testimony he was convicted and executed; and no greater dishonor rests on the name of Bacon than that he assisted his master, King James, in corrupting the judges of the king's bench into a willingness to convict of treason one Peacham, a parish priest, on the evidence of a sermon which he had never delivered, and which was found by searching his study. Out of the many civil conflicts and commotions in England, and especially the wars of the roses, there grew one rule, still in force, and resting on the soundest justice and reason. During those ages of constant disturbance, when there were frequently more persons than one who claimed the crown, and, so far as they could, exercised royal authority, almost every person incurred the danger of treason, in case the claimant to whom he adhered was defeated; and for this cause, or on this pretence, multitudes of men of every rank perished on the scaffold. But from the obvious absurdity of exacting from every individual a sound, or rather a fortunate judgment as to the obscure and complicated grounds on which the claim to sovereignty often rested, it became and still remains a well settled rule, that no one incurs the guilt of treason by adherence to a king or government *de facto*, although that king or government has but the right of a successful rebel, and loses it all by a subsequent defeat.—In considering the crime of treason in the United States, we must remember that there may be treason against the United States, and also treason against any one of the states. Looking first to treason against the United States, the foundation of the law itself, and of our knowledge of it, must be the clause in the constitution already quoted; and as there is no common law of the United States, this clause would have remained inoperative but for the act of congress of 1790, chap. 36, sec. 1, whereby it was enacted, "that if any person or persons owing allegiance to the United States of America, shall levy war against them, or shall adhere to their enemies, giving them aid and comfort within the United States

or elsewhere, and shall be thereof convicted, on confession in open court, or on the testimony of two witnesses to the same overt act of the treason whereof he or they shall stand indicted, such person or persons shall stand adjudged guilty of treason against the United States, and shall suffer death." When the courts came to the construction and application of that act, they very properly made use of the principles and the jurisprudence of the common law; and they could do this the better, because the clause of the constitution is substantially the same as a provision of the statute of Edward III., and the best ability of England had been carefully employed about that statute. For a judicial exposition of that clause and that statute, we must look to the trial of Burr, and of Bollman and Swartwout (4 Cranch, pp. 75 to 187), although these are not the only cases in which the same subject has been considered.—The first question is: What is a levying of war against the United States, within the meaning of the statute? In the first place, the levying of war must be actual; it must be carried out into some practical operation and effect. No intention, and no extent or thoroughness of preparation or of conspiracy for war, constitutes the crime of treason until the war actually begins. Some kind of force or violence, it is said, must be used. But it would seem that this force may be what the law would call constructive force; and it may be very slight; for it certainly need not be sufficient to accomplish either the general purpose of the war, or the particular effect proposed. But, if there be any overt act of war, then every one aiding and abetting this act of war, however remotely, does himself levy war, and commit treason. It must be difficult to determine always what this rule requires. Thus, Marshall declares, that if an army be actually raised for the avowed purpose of carrying on war against the United States, and subverting their government, the point must be weighed very deliberately, before a judge would venture to decide that an overt act of levying war had not been committed by a commissary or purchaser who never saw the army, but who, knowing its object and leaguering himself with the rebels, supplied that army with provisions; or by a recruiting officer, holding a commission in the rebel service, who, though never in camp, executed a particular duty required of him. Hence it would follow, that if there be an act of levying war against the United States, persons may be participators of that act, and of the crime which it constitutes, although they reside as far as possible from its actual locality. The prevailing rule of the criminal law, that there may be principals and accessories to a crime, has no application whatever to treason. We are warranted by the language of Chief Justice Marshall in saying, that if a rebellion were so extensive as to spread through every state in the Union, every individual concerned in it is not legally present at every overt act

committed in that rebellion; nor can it be said that even the commander-in-chief of the rebel army, or the head of the organized rebellion, is legally present at every such overt act. But while a man may be actually absent, yet if he have counselled or procured the treasonable act, he is a principal traitor, not because he is legally present, but because in treason all are principals. This question of locality has yet another importance. A person charged with this crime can be tried only within the state or judicial district in which it is committed, and the alleged criminal has indeed a strict right to be tried by a jury within that state or district. A wide extent may be given to this rule, by the doctrine that in treason all are principals, as above stated; but it can apply only to those persons who would, in the locality in which they reside, be either principals or accessories if there could be accessories to this crime. For if a person commits his own act of treason in a certain locality, and is not connected with any one committed elsewhere, so as to be, in this way, a principal in the act, he can be tried only within his locality; and if the judicial tribunals of the United States cannot or will not perform their proper functions within that state or judicial district, he cannot be tried anywhere. It is certain, too, that the overt act which is alleged to be a treasonable act, must have been done with "a treasonable purpose." We have on this point high authority for saying, that if the object of the act be to prevent by force the execution of any public law of the United States, that is a treasonable purpose, for it aims at overthrowing the government as to one of its laws. So, if the purpose be to overthrow the government at one place, large or small, that is a treasonable purpose.—What, then, is adhering to an enemy, or, in the language of the constitution, giving him aid and comfort? It is perhaps impossible so to define these words as to make their meaning any plainer. But, again on high authority, this meaning may be illustrated thus: If a conspiracy to levy war against the United States be in actual operation anywhere within it, any citizen, residing anywhere else and at whatever distance, if he supply the rebels with arms or any munitions of war, with provisions to be used in support of the war or of the rebels while carrying it on, or money, or intelligence or information, and even if none of these things reach the rebels, he becomes a traitor in the place where he resides. So it would come under this branch of treason, if forts, castles, or ships of war were delivered to the enemy, or if the accused had joined the enemy's forces, though no battles or conflicts take place.—Of treason against one of the states of the Union, little need be said. It has been asserted, though never judicially, that there can be no treason in this country excepting against the United States. This point was taken in defence of the accused, in the trials which took place after the suppression of what is called the Dorr

rebellion in Rhode Island. It was fully considered by the court and distinctly overruled; and it seems to be now certain that treason may be committed against any one of the states. As to what constitutes treason, the same principles would undoubtedly apply, whether the treason charged were committed against the United States or against any one of the states, qualified only by any special provisions of the constitution or law of that state. The crime is expressly recognized by the legislation of many of the states; and in New York, Massachusetts, Pennsylvania, and Virginia, and perhaps in other states, cases have occurred where the general principles of the law in relation to treason have been acknowledged and applied. It needs only to be added, that treason against a separate state can consist only in an act of hostility against the sovereignty of that state, as distinct from the sovereignty of the United States. There cannot be, we presume, an act of treason against the United States and any state jointly, or against two or more of the states jointly.—As all treason consists of hostility against a state by one who owes to it allegiance, so only one who owes this duty, in some way, may be a traitor. But it is held that this modified allegiance may be that of an alien residing in this country and enjoying the protection and advantages of its government. The allegiance of an alien, however, or the possibility of his becoming a traitor, ends with his residence in this country; while the duty of allegiance goes with a citizen wherever he goes; and wherever he may be, he becomes a traitor by hostility against the government in violation of this duty.—We have seen that no one can be convicted of treason except on the evidence of two witnesses; but with this exception, the trial for treason is conducted in all respects like any other criminal trial for a capital offence. If convicted, the traitor suffers death, by the ordinary means of execution. We have no remnant of that ferocious cruelty, which may have been necessary in any age or nation so barbarous as to have made it a part of its law. Until the 80th year of George III. the convict of treason forfeited his property to the crown, was drawn on a hurdle to the gallows, there hanged, then cut down, disembowelled, and his entrails burned before life was extinct; and the body was then beheaded and quartered. But, while it is difficult to believe that such cruelty could have been often practised, the recollection of these enormities, or of all the abuses of the law of treason, should not lessen our abhorrence of this enormous crime.

TREASURE TROVE (literally, found treasure), a term applied to money, coin, plate, or other forms of the precious metals, found hidden in the earth or any private place, and for which no owner or depositor can be discovered. By the common law of England such property becomes vested in the sovereign, if it appears to have been concealed with the intention of reclaiming it. In all other cases, as where cir-

umstances show that the treasure was intended to be abandoned, it belongs to the finder, who by a special order in council is also entitled to the commercial value of ancient coins and other objects of antiquarian interest, under whatever circumstances they may be found. The civil law formerly gave the treasure trove to the finder; or if found on another man's land, it was divided between them; but the practice in continental Europe has in modern times been similar to that in England. During the middle ages treasure trove constituted an important source of revenue to the crown; but with the increased security of property the practice of burying money, so prevalent in troubled times, as in a great measure ceased, and the instances in which the sovereign is enabled to claim his prerogative are comparatively rare.

TREASURY, literally, a place or building in which money or other treasure is stored for safe keeping, but more generally understood as a department of government having control of the collection, management, and expenditure of the public revenue. In England the lord high treasurer, the third great officer of the crown, was formerly the sole head of the treasury; but since the time of George I. the duties of his office have been discharged by 5 lords commissioners, consisting of the first lord of the treasury, who is also the prime minister, the chancellor of the exchequer, and 3 junior lords. The departments immediately subordinate to the treasury are numerous and important, and the amount of patronage thereby thrown into the hands of the premier is more considerable than in any other branch of the public service. The first lord of the treasury is generally the leader of the ministerial party in parliament for the house in which he sits, and the chancellor of the exchequer assumes similar functions in the absence of his superior. Hence the term treasury benches applied to the seats occupied by the ministry. The treasury department of the United States is under the management of a secretary, an assistant secretary, a chief clerk, comptrollers, 5 auditors, a treasurer, several assistant treasurers, and other officers, having in charge the fiscal concerns of the government.

TREBIZOND, a pashalic of Asiatic Turkey, bounded N. by the Black sea, E. by Kars, S. by Erzurum, and S. and W. by Sivas; extreme length about 220 m., breadth 50 m.; area, about 7,000 sq. m. The chief towns, beside the capital, are Keresoon (anc. Cerasus), Trebizi (Tripolis), Rizah (Rhizus), and Batoom (Bathys). The scenery on the coast is remarkably beautiful. The mountains rise immediately from the sea to the height of nearly 5,000 feet, and are clothed with dense forests. The country is generally well wooded and mountainous, and has but little arable land. The principal rivers are the Tchörük, on the E. frontier, and the Kharsat, neither very large. The climate is variable, being subject to cold winds, accompanied by rain and fog from the

Black sea. There are several fertile valleys and well cultivated tracts, but the country does not produce sufficient grain for the consumption of the population. The inhabitants are a hardy, bold race, and the men always go armed. They are good marksmen, and each carries a rifle slung across his shoulders.—**TREBIZOND**, or **TARABOZAN** (anc. *Trapezus*), the capital, is situated on the S. E. coast of the Black sea, in lat. 41° 3' N., long. 39° 46' E.; pop. about 50,000. It is divided into two parts, the Turkish and the Greek, the former surrounded by walls and separated from the latter by a ditch crossed by two narrow bridges, defended by fortified gateways. The most remarkable building is the citadel, which stands upon the flat top of a steep rock. The bazaars are extensive, and the public baths are constructed of marble. The anchorage is in a small open bay, and is only considered safe during the summer months; and at other seasons vessels lie at Platena, a roadstead about 7 m. W. from Trebizond. It is now considered the first commercial port on the Black sea, and, after Constantinople, in the Turkish empire. Five lines of steam vessels connect it with the principal ports of Asia and Europe, which in 1859 brought thither 49,086 passengers. An extensive overland trade is carried on with Armenia, Georgia, and Persia. The goods received from these countries consist of silk, wool, tobacco, wax, gall nuts, oil, opium, different sorts of drugs, honey, timber, carpets, and shawls, many of which are reexported. The imports by sea comprise cotton cloths, glass, cutlery, firearms, and other manufactures, together with grain, iron, tin, spices, and the produce of tropical regions. The total trade has increased from about \$6,000,000 in 1833 to \$38,000,000 in 1859; the imports in the latter year amounted to \$18,648,650, and the exports to \$19,490,261; arrivals and departures, 626, tonnage 288,174.—**Trapezus** was founded by a colony from Sinope, and was a flourishing town when Xenophon arrived there on his retreat from Persia. It became subject to the Romans by conquest from Mithridates. The emperor Trajan constructed a mole to improve the port, and made it the capital of eastern or Cappadocian Pontus. During the reign of Gallienus it was plundered and nearly destroyed by the Goths, but in the time of Justinian it had completely recovered, and was made the capital of a province which included Pontus and some part of Armenia. In 1204 it became the seat of an independent branch of the Comnenus family (see *ALEXIS*, vol. i. p. 334), who afterward called their territory the empire of Trebizond, and held it through a succession of 20 sovereigns till 1462, when it succumbed to the power of the Turks.

TREDGOLD, THOMAS, an English civil engineer, born at Brandon, near Durham, Aug. 22, 1788, died in London, Jan. 28, 1829. At 14 years of age he was apprenticed to a cabinet maker at Durham, and in 1808 went to Scotland, where he worked 5 years as a journeyman carpenter

and joiner, and by his excessive devotion to study at night and in the intervals of labor impaired his constitution. In 1818 he went to London, and entered the service of a relative, William Atkinson, architect to the ordnance, with whom he remained for several years, while continuing his studies, and in 1828 commenced as civil engineer on his own account. Beside numerous articles in periodicals, he published "Elementary Principles of Carpentry" (4to., London, 1820); "A Practical Essay on the Strength of Cast Iron and other Metals" (8vo., 1821); "The Principles of Warming and Ventilating Public Buildings, Dwelling Houses," &c. (8vo., 2d ed., 1824); "A Practical Treatise on Railroads and Carriages" (8vo., 1835); "Remarks on Steam Navigation, and its Protection, Regulation, and Encouragement" (1835); and "The Steam Engine, comprising an Account of its Invention and progressive Improvement, with an Investigation of its Principles," &c., the last edition of which (1862) is enlarged to 4 vols. 4to., illustrated with 226 steel plates and 164 woodcuts.

TREE. See ARBORICULTURE.

TREE FROG, the name of the batrachian reptiles of the family *hylææ*, distinguished from common frogs (*ranida*) by having the ends of the fingers and toes dilated into flattened disks or suckers, which enable them to lead their peculiar arboreal life. They are of more elegant form, smaller size, brighter colors, and more active habits than the *ranida*, and are lively during the day; they feed on insects, which they pursue on bushes and trees, stealing toward them or suddenly springing and swinging upon them; they climb like the geckos among lizards, and by the same mechanism; the lower surface of the disks is endued with a viscid secretion, by means of which they can walk with the body suspended from the under parts of leaves and other smooth bodies; the skin is mostly smooth upon the back, but on the abdomen and inside of legs thickly studded with small warts or tubercles. They possess to a remarkable degree the faculty of changing color, by the modifications of the contents of the pigment cells under the skin, no doubt a provision to enable them to elude their numerous enemies. They are very clamorous, and particularly noisy at the approach of rain; in winter they bury themselves in the mud at the bottom of pools; they breed in the spring, depositing their eggs in the water. They are frequently called tree toads, and their French name is *rainettes*. The species are numerous, especially in America; only one is found in Europe, and that also occurs in N. Africa and Asia; no fossil traces of the family have been discovered, according to Pictet.—The common tree frog of North America (*hyla versicolor*, Le Conte) resembles a toad in form, but is more flattened; body short and warty above, the color varying from pale ash to dark brown, with several large irregular blotches of greenish brown, white and granulated below, and

abdomen yellowish near the thighs; the colors vary at the will of the animal. The head is short and rounded, the mouth large, with teeth on upper jaw and vomer; eyes large and brilliant, the iris bright golden; there are 4 fingers and 5 toes, both ending in viscid pellets, the former distinct, but the latter webbed for $\frac{1}{2}$ of their length. It is about 2 inches long, and is found abundantly in the northern and middle states, and as far west as the Mississippi; it is generally seen on decaying trees and about old fences of wood or stone, overgrown with mosses and lichens, the color of which it so nearly resembles that it is very difficult to detect; it is very noisy in spring and summer toward evening, especially in cloudy weather, and its liquid and abruptly terminating note must be familiar to all residents in the country; the secretion of the skin is copious and very acrid. This species in the southern states is replaced by the green tree frog (*H. viridis*, Laur.; *calamita Carolinensis*, Penn.), which is bright green above, yellowish white below, with a straw-colored lateral line extending from the upper jaw over the shoulder and along the side; it is shorter and more slender than the northern species; and is most commonly seen about broad-leaved plants, especially Indian corn, the color of the leaves of which it greatly resembles, concealed during the heat of the day, but coming out morning and evening and becoming very active and noisy; the single note is clear and bell-like; the food consists of insects, particularly the common fly, to seize which it leaps a foot or more; on the ground when in search of water leaps of 8 or 10 feet are sometimes made. The *H. squarrela* (Daud.), sometimes improperly called the peeping frog, is olive-green above, with brown blotches, a transverse dusky band between the orbits, and whitish below; it is about 1½ inches long, not found N. of Virginia, and has remarkable powers of changing color. Several other species are described by Holbrook and more recent authors, from the southern and south-western states and territories. The tree frog of Europe (*H. arborea*, Linn.) much resembles the green species of North America, and the latter was considered by Laurenti a variety of his *H. viridis*; it is spread throughout Europe, except in Great Britain.—In the genus *acris* (Dum. and Bibr.) the locomotive disks are less developed and the limbs more slender than in *hyla*, and there are teeth on the palate instead of the vomer. The *A. gryllus* (Dum. and Bibr.) or Savannah cricket, is about 1½ inches long, with an elongated pointed head, a triangular dusky spot between the orbits; body ash above, with a green and sometimes reddish dorsal line, and 3 oblong black spots margined with white on the sides. It is a lively species, constantly chirping like a cricket, even in captivity; it frequents the edges of pools, and is sometimes found on the leaves of aquatic plants; it may easily be domesticated so as to take food from the hand; it makes immense leaps; it co-

curs from southern New England to the gulf of Mexico; it is intermediate between the *rani-*das and *hylas*, having the aquatic habits of the former and the method of watching for its prey of the latter; in consequence of the smallness of the disks it cannot adhere to the under surface of smooth bodies.—In the genus *hylodes* (Fitz.) the palate is toothed, and the slender fingers and toes are free, with small disks. Pickering's tree frog (*H. Pickeringii*, Holbr.) is nearly an inch long, with short head and yellowish brown body, with dusky rhomboidal spots and lines, sometimes like the letter X on the back; pale flesh-colored below, tinged with yellowish on the throat. This is the true peeping frog, the noise being made by both sexes; in summer they cease to be vocal, retiring from the pools where the eggs were laid to the woods, where they live on trees, hopping about on the branches in search of insects, and occasionally uttering a shrill whistle. It is found in the New England and middle states, and was named in honor of Dr. Charles Pickering, who obtained it abundantly in the vicinity of Salem, Mass. The chestnut tree frog (*H. lineatus*, Dum. and Bibr.) is about 2 inches long, brownish and sometimes bluish above, with a yellowish white line from the nose to the arm pit; below bluish white. It is a native of Cayenne; the young adhere to the back of the mother, without the assistance of the dorsal pits of *pipa* (see Toad); though having the gills and swimming tail of the tadpole, they are often found on the parent's back at a considerable distance from water. In *notodolphys orifera* (Weinland), from Venezuela, a dorsal fissure in the female leads to two lateral pouches in which the eggs are carried, and in which the embryo is developed until the feet are produced.—In the genus *dendrobates* (Wagler), which seems to connect this family with the toads, there are no teeth in the upper jaw, but the fingers and toes end in disks, enabling the species to lead an arboreal life. The *D. tinctorius* (Wagl.) was so named from the statement that the natives in South America are in the habit of pulling out the feathers from young green parrots, and rubbing the blood of the batrachian on the bare place, it being believed that the new feathers there growing will be red or yellow; it is about 1½ inches long, ferruginous above with 2 longitudinal white stripes.

TREFOIL. See CLOVER.

TREMBECKI, STANISLAW, a Polish poet, born in the palatinate of Cracow about 1724, died at Tulczyn, Dec. 12, 1812. He travelled extensively, became intimate with the principal literary men of France, fought some 80 duels on account of love affairs, was noticed for peculiarities in dress, diet, and manners, served for some time as chamberlain to King Stanislas Augustus, and spent the last years of his life at Tulczyn, a country seat of Count Felix Potocki. His miscellaneous poems have appeared in various collections, the last edition being that of Leipzig, 1836, in 2 vols.

TREMBLEY, ABRAHAM, a Swiss naturalist, born in Geneva in 1700, died in 1784. He was tutor to the children of Lord Bentinck, English minister at the Hague, and afterward to the duke of Richmond, with whom he visited Germany and Italy. On his return to Geneva in 1757 he was appointed a member of the great council. In his *Mémoires pour servir à l'histoire d'un genre de polytypes d'eau douce, à bras en forme de cornes* (Leyden, 1744), he demonstrated that these creatures, which had previously been classed in the vegetable kingdom, were really animals. He left also several works of a religious character.

TREMPELEAU, a W. co. of Wisconsin, bounded S. W. by the Mississippi river, intersected by Trempeleau Mountain river, and drained also by Black and Buffalo rivers; area, 684 sq. m.; pop. in 1860, 2,550. The surface is level and the soil fertile. Capital, Galesburg.

TRENCH, RICHARD CHENEVIX, D.D., a British clergyman and author, born in Dublin, Sept. 9, 1807. He is the second son of Richard, brother of the first Lord Ashdown in the Irish peerage, and of Melesina, granddaughter of Dr. Richard Chenevix, formerly bishop of Waterford. He was graduated at Cambridge in 1829, and after a few years of travel took orders, became a country curate, and published two volumes of poems respectively entitled "Sabbation, Honor Neale, and other Poems," and "The Story of Justin Martyr." These, being favorably received, were succeeded by "Genoveva," "Elegiac Poems," and "Poems from Eastern Sources." In 1841 he became curate to the present bishop of Oxford, then at Alverstone, and in 1845 was presented by Lord Ashburton to the rectory of Itchenstone. He was appointed in 1845 examining chaplain to the new bishop of Oxford, and was also Hulsean lecturer at Cambridge during 1845-'6, and in 1847 was appointed theological professor in King's college, London. On the death of Dr. Buckland in 1856, he was appointed by Lord Palmerston dean of Westminster, which dignity he now holds. Dean Trench has acquired a high reputation as a writer on theological subjects, and as a philologist and poet. His chief religious works are: "Notes on the Miracles," "Notes on the Parables," "The Sermon on the Mount," "Sacred Latin Poetry," "Saint Augustine as an Interpreter of Scripture," "Sermons on the Divinity of Christ," and "Commentary on the Epistles to the Seven Churches in Asia" (1861). His principal philological works are: "On the Authorized Version of the New Testament;" "On the Study of Words," a series of lectures (1851), of which the 9th English and 23d American editions were published in 1861; "On the Lessons in Proverbs," "Synonymes of the New Testament," "English Past and Present," and "A Select Glossary of English Words used formerly in Senses different from their present." He has also written a work entitled "Calderon, his Life and Genius, with Specimens of his

Plays," and edited "The Remains of the late Mrs. Richard Trench," his mother (London, 1862).

TRENCK, FRANZ VON DER, baron, an Austrian military leader, born in Reggio, Calabria, Jan. 1, 1711, committed suicide in prison at Brunn in 1749. In his 17th year he entered the Austrian military service, but was obliged to leave it in 1788 on account of his insubordination and excesses, and became captain in a Russian hussar regiment. Twice condemned to death for serious violations of discipline, he was saved by Marshal Münnich, and after 6 months' penal labor retired to his estates in Slavonia. In 1740, on the breaking out of the war of the Austrian succession, he was permitted by the empress Maria Theresa to raise a corps of Pandours at his own expense, which soon numbered 5,000 men. At the head of these he served in the war of the succession and in the 7 years' war which followed, and distinguished himself by his courage and military capacity, but still more by his cruelty and rapacity. Having at length, while undergoing trial by court martial, throttled one of the judges and attempted to throw him out of a high window, he was condemned to perpetual imprisonment in the fortress of Brunn in Moravia, where he poisoned himself. He possessed astonishing physical strength, united with a disposition of extraordinary ferocity. His autobiography appeared at Vienna in 1807, under the title of *Merkwürdiges Leben und Thaten des Freiherrn Franz von der Trenck*; and his life has been written by Hübner, under the title of *Franz von der Trenck, dargestellt von einem Unparteiischen, mit einer Vorrede von Schubart* (8 vols., Stuttgart, 1788).—FRIEDRICH VON DER, baron, a German soldier and adventurer, cousin of the preceding, born in Königsberg, Feb. 16, 1726, guillotined in Paris, July 25, 1794. He was educated at the university of Königsberg, was admitted in 1742 into the body guard of Frederic the Great, and when only 18 years old was selected to instruct the Silesian cavalry. During the following winter he engaged in a secret intrigue with the princess Amelia, second sister of the king, and to this circumstance, it has been thought, his after misfortunes were owing. In the campaign of 1744 he served with great distinction, acting as the adjutant of Frederic, with whom he became a special favorite. On his return to Berlin his amour came to light, or at least was suspected by the king, and Trenck was arrested and confined for several weeks for having been a few minutes late on parade. In the campaign of 1745 he again distinguished himself; but having corresponded on private affairs with his cousin Baron Franz, then in the Austrian service, he was cashiered, and without trial conducted to the fortress of Glatz, where he was imprisoned for more than a year. After several desperate efforts he escaped, went to Vienna, and exerted himself to procure the pardon of his cousin, who was

then undergoing a trial. His efforts were ungratefully received by the baron, and led to much trouble and a number of duels. At Nuremberg he met the Russian general Liouven, who was marching with an army to the Netherlands, and who persuaded him to enter the Russian service, and gave him a company of dragoons in the Tobolokoi regiment. After the peace he was received with much favor at Moscow, though his advancement was retarded by the efforts of Goltz, the Prussian ambassador. His cousin, having died, left him heir to his estate, but on condition that he should become a Catholic and should serve only the house of Austria. To secure this he went to Vienna in 1750, but out of all this bequest and the property of his uncle he received only 63,000 florins, with which he purchased the lordship of Zwerbach. By the Austrian court he was made captain of cavalry in the Cordova cuirassiers. In March, 1754, his mother dying, he made a journey to Dantzic to settle some family affairs, and was there apprehended by the Prussian authorities, carried to Berlin, and thence taken to Magdeburg. There he was confined in a dungeon in the citadel. His apartment was in a casemate, the fore part of which was 6 feet wide and 10 feet long, and was divided by a party wall. He was at first not put in irons, but a desperate effort to escape caused him to be removed, May 27, 1755, to a cell in the Star fort, which was made especially for his confinement. Enormous chains were fixed to his ankle at one end, and at the other to a ring fastened in the wall about 3 feet from the ground. A huge iron ring of a hand's breadth was riveted around his naked body, from which hung a chain fixed into a thick iron bar 2 feet in length, at each end of which was a handcuff. The dungeon was built in the ditch of the fortifications, and when Trenck entered it had been finished only 11 days, so that during the first 3 months he was kept constantly wet by the water dropping from the moist lime and plaster. Even under these circumstances he nearly succeeded in making his escape. In 1756 a massive iron collar was put around his neck and connected with the chains of the foot by heavy links. In this condition he lay imprisoned until Dec. 24, 1763, enduring sufferings of a most terrible character, and repeatedly making the most daring attempts to free himself. On that day he was released by order of Frederic, and in Jan. 1764, was carried to Prague, where he endured renewed persecutions from the men who had control of his estates. Disappointed of preferment at the Austrian court, he retired to Aix la Chapelle, married there in 1765, and lived for several years in peace, occupying himself in writing a series of periodical essays, called *L'ami des hommes*, in which he advocated opinions of a liberal character, and in particular attacked the Roman Catholic church. In 1767 appeared his poem of "The Macedonian Hero," which gave him considerable reputation in Ger-

many. He also engaged in the wine trade, in which he was very successful at first, but once while in London was defrauded to so large an amount that he gave up the business. From 1774 to 1777 his time was spent chiefly in travelling through England and France; and in the latter country he became intimate with Dr. Franklin, then American minister, and the counts St. Germain and De Vergennes, who made him advantageous proposals to go to America, which he was prevented from accepting by his affection for his family. The landgrave of Hesse-Cassel also offered him a commission in the army going to America to assist the British, which he refused, saying: "My heart beats in the cause of freedom only; I will never assist in enslaving men. Were I at the head of your brave grenadiers, I should revolt to the Americans." Subsequently he retired to his estate at Zwerbach, and spent several years in agricultural pursuits; but his property having been entirely ruined by floods and storms, he repaired his broken fortune by publishing a collection of his works and a history of his life. These gained him money and reputation, especially the autobiography, which was extraordinarily successful. After the death of Frederick in 1786 the confiscation of his estates was annulled, and he was permitted to return to his native country. Here he might have lived in quietness, but at the breaking out of the French revolution his restless spirit drove him to Paris, where he was arrested by the committee of public safety and put to death on the charge of being a secret emissary of the king of Prussia.

TRENT, a river of England, which rises in Staffordshire, 4 m. N. from Burelem, flows through the central part of the island, and near Burton-on-Strather, Lincolnshire, joins the Ouse to form the estuary called the Humber, which falls into the North sea between Spurn Head in Yorkshire and Donna Nook in Lincolnshire; total length of the Trent and Humber, 190 m. Its course is very circuitous, but is in a general E. and N. direction to its junction with the Ouse, from whence it flows easterly for about 50 m. to the sea. It is navigable as far as Gainsborough for vessels of 200 tons, and to Burton-on-Trent for barges of 25 tons. Its chief tributaries beside the Ouse are the Sow, Tame, Par, Dévon, Blyth, Dove, and Derwent; and is connected with several other rivers and navigable waters by a series of canals.

TRENT (Ital. *Trento*; Ger. *Trient*; anc. *Tridentum*), a walled town of Austria, in the Tyrol, capital of a circle of the same name, situated on the left bank of the Adige, 18 m. N. N. from Roveredo, and 72 m. N. W. from Venice; pop. about 15,000. It stands in a small and very beautiful valley among the Alps, and from its elevation the climate is exceedingly cold in winter, while the reflection of the sun's rays from the surrounding mountains makes it remarkably hot in summer. The streets are most wide and well paved, and the houses are in the Italian style and generally well and regu-

larly built. It has a cathedral built entirely of marble in the Byzantine style in 1212. The church of Santa Maria Maggiore is built of red marble, and is interesting as the place where the celebrated council of Trent held its meetings. The manufactures are not important, but it is one of the seats of the transit trade between Italy and Germany.—Tridentum is supposed to have been founded by the Rhæstians of Etruria. The Romans colonized it, and on the decline of that empire it passed successively into the hands of the Cénomani, Goths, Lombards, and dukes of Bavaria. During the middle ages it became a free imperial city under its bishops, who were princes of the empire with a vote in the diet at Ratisbon until 1802, when its government was secularized.

TRENT, COUNCIL OF, the last œcumenical council of the Roman Catholic church. The first occasion for an œcumenical council in the 16th century was furnished by Luther and the Protestant princes, who appealed from the decision of the pope to a council. This appeal was supported by the Catholic princes, and the emperor Charles V., at the diet of Ratisbon, promised to induce the pope to convoke the council. Three popes, however, Leo X., Adrian VI., and Clement VII., died before the demands of the Germans were complied with. Paul III. appointed it to convene at Mantua, May 27, 1537; but when the duke of Mantua objected, Vicenza was selected. The war between the emperor and the king of France, and the conference between Catholics and Protestants at Ratisbon in 1541, caused new delays. At length Paul III. convoked it for Nov. 1, 1542, but on account of the war with France again put off the day of opening to March 15, 1545. The actual opening, owing to the tardy arrival of bishops and ambassadors, did not take place until Dec. 13, 1545. The objects of the council were to effect a reformation of the church, to define more explicitly the impugned doctrines of the church, and, if possible, to induce the Protestants to return to the old faith. At the 2d session (Jan. 7, 1546) the council fixed the mode of transacting business. The discussions and deliberations were to take place in private congregations; subsequently general congregations were to draft the resolutions, which finally were to be promulgated in public sessions as decrees. In the 3d session (Feb. 4) the Nicene creed was read and declared to be the basis of the further proceedings. In the 4th session (April 8) tradition was declared to be equally with the Bible a rule of faith; the Apocrypha of the Old Testament were included in the canon of the Bible; the Vulgate was proclaimed to be the authentic version of the Bible, and the church its only legitimate interpreter. In the 3 following sessions (June 17, 1546; Jan. 13 and March 3, 1547), the Catholic doctrines of original sin, justification, and the sacraments were defined, and an anathema pronounced upon all who rejected these doctrines. In the 8th session (March 8), 88 of the 56 bishops pres-

ent, together with the papal legate, decreed, on the ground of being exposed at Trent to the plague, to adjourn to Bologna, notwithstanding the decided opposition of the emperor, at whose request 18 German and Spanish bishops remained at Trent. At Bologna, where 6 archbishops, 32 bishops, and 4 generals of religious orders were present, the 9th and 10th sessions were held (April 21 and June 2); but, at the express order of the pope, who had some apprehensions of a schism, no decrees were promulgated, except decrees of prorogation. As the emperor could not be prevailed upon to recognize the council of Bologna, the council was indefinitely prorogued by a bull of Pope Paul III., dated Sept. 17, 1549. The pope died in Nov. 1549, and on May 1, 1551, the council was reopened at Trent by order of his successor Julius III. France protested against the continuation, and all the French bishops and theologians withdrew. In the succeeding transactions the Jesuits Lainez and Salmeron, who were sent to the council as papal theologians, took a leading part. There appeared also representatives from the Protestant princes of Württemberg and Brandenburg, and even Melancthon was summoned there by order of the elector Maurice of Saxony; but it was found impossible to effect a reunion, and soon the outbreak of a new war of the Protestant princes against the emperor caused the assembled fathers (April 28, 1552) to suspend their deliberations. During this period, extending from the 11th to the 16th session, the doctrines of the eucharist, of confession and extreme unction, and two reformatory decrees on the jurisdiction of the bishops, were promulgated. Paul IV. was anxious to assemble the council at Rome, but Pius IV. consented to its reopening at Trent, which took place on Jan. 18, 1562, through the cardinal legate Prince Hercules Gonzaga of Mantua. France and the German emperor demanded very urgently a thorough reformation, and in particular the concession of the cup to the laity, and the abolition of celibacy and fasting; but their proposition was voted down. On Nov. 18 the cardinal of Lorraine arrived, with 14 bishops, 3 abbots, and 18 theologians from France, and presented in the name of his nation 34 reformatory articles, but subsequently abandoned their advocacy. On the question whether the dignity and rights of the bishops are of papal or of divine origin, the bishops found it impossible to come to an agreement, and it was consequently left undecided. Decrees were adopted ordering an index of prohibited books to be made, and defining the doctrines of the mass, ordination, the hierarchy, marriage, celibacy, purgatory, the veneration of saints, relics, and images, monastic vows, indulgences, and fasting and abstinence. A number of "reformatory" decrees were also passed, the most important of which enjoins the establishment of theological seminaries. The close of the council was hastened by a serious sickness of the

pope, and his fear that his death might lead to a schism. It took place on Dec. 4, 1563, at its 25th public session. The decrees were signed by 255 members, consisting of 4 legates, 2 other cardinals, 3 patriarchs, 25 archbishops, 168 bishops, 39 representatives of absent bishops, 7 abbots, and 7 generals of religious orders. An authentic copy was also signed by the ambassadors of the secular governments, with the exception of the ambassador of Spain, who was without instruction, and the ambassador of France, who was absent. The decrees were confirmed by the pope, with the unanimous consent of the cardinals, in the consistory of Jan. 28, 1564; but the pope reserved to himself the right of explaining obscure or controverted points. The council was accepted unconditionally by most of the Italian states, by Portugal, Poland, and the German emperor; with a reservation of the royal prerogatives by Spain, Naples, and the Netherlands; with some exceptions by Switzerland and Hungary; and only so far as respects doctrines by France. The "Canons and Decrees" of the council were printed by Aldus (Rome, 1564). The "Catechism," an authorized summary of the faith drawn up by order of the council, appeared at Rome in 1566, and the collection of documents relating to its history was edited by Le Plat (7 vols. 4to., Louvain, 1781). The first complete history of the council was written by the Servite monk Paolo Sarpi (London, 1619; English translation by Brent, London, 1676), in a spirit of decided opposition to the papal court. Against him wrote the Jesuit Pallavicino (2 vols., Rome, 1636-'7). A work on the discrepancies of both has been published by Dr. Brischar (3 vols., Tübingen, 1843). Mendham's "Memoirs of the Council of Trent" (London, 1884) contains extracts from 28 volumes of manuscripts collected in Italy by Lord Guilford. The publication of the original acts and the diary of the council, by Augustine Theiner, prefect of the Vatican library, has been promised.

TRENTE-UN. See ROUGE ET NOIR.

TRENTON, a city and the capital of New Jersey and of Mercer co., situated on the left bank of the Delaware river at the confluence of Assunpink creek, and at the head of steamboat navigation, 30 m. N. E. from Philadelphia, and 57 m. S. W. from New York; pop. in 1860, 17,221. Its situation on the Delaware commands a fine view of the river and the fertile region on the W. bank. The city is regularly laid out, and lighted with gas, and has many elegant stores and residences. Main street is the principal business thoroughfare, and State street has the greatest number of fine residences. Assunpink creek divides the city into nearly equal parts. The 3d, 4th, and 6th wards lie south of the creek, and the two first named formerly composed the borough of South Trenton, which was united to Trenton in 1851. The 6th ward, formerly Lamberton, was annexed to the city in 1856. Water is

raised from the Delaware to a reservoir N. of the city. The capitol is a handsome stone building, 100 feet by 60, stuccoed in imitation of granite. The county court house is in South Trenton, and is a fine building of brick, stuccoed. There is also a good town hall. Trenton also contains the state lunatic asylum, founded in 1848, and having accommodations for 825 patients; the state normal school, established in 1855, and having extensive buildings admirably adapted for its purpose, with 100 pupils in 1880; and the state penitentiary, which on Jan. 1, 1860, had 317 inmates. There is a state library of 8,000 volumes, beside a valuable law library, and a public library of about 2,000 volumes. There are 2 banks, each with a capital of \$350,000, and 22 churches, viz.: 2 Baptist, 3 Episcopal, 2 Friends', 2 Lutheran, 7 Methodist, 4 Presbyterian, and 2 Roman Catholic. Five newspapers are published in the city, 3 of which are daily. There are 2 wooden bridges over the Delaware opposite the city, one 1,100 feet long, built about 1810, and crossed by the Philadelphia and Trenton railroad, and the other about 1,800 feet long, completed in 1860. The Delaware and Raritan canal passes through the city, forming a water communication with Philadelphia and New York, and, by the navigable feeder of the canal, with Lambertville and New Hope, about 18 m. N. Trenton is connected with Philadelphia by the Philadelphia and Trenton and Camden and Amboy railroads, and with New York by the Camden and Amboy and New Jersey railroads. The Belvidere Delaware railroad connects with the Camden and Amboy road at this point; at Easton, 56 m. N. of Trenton, it connects with the Lehigh Valley railroad, and only awaits the completion of a short branch road from Belvidere to connect it with the Lackawanna and Western road at the Delaware Water Gap. The city has 4 iron foundries; a locomotive and machine factory, now (1862) engaged in casting and finishing large guns; 2 wire factories; a wire rope factory and a rolling mill, both the largest of their kind in the United States; a manufactory of edged tools, swords, &c.; a malleable iron foundry; 2 manufactories of granite or white porcelain ware, and of yellow and Rockingham earthenware, which together make about half the ware of these descriptions produced in the United States; a manufactory of terra cotta, and one of fire brick; a large cotton and woollen manufactory, 4 paper mills, 3 flouring mills, 2 steam saw mills, 2 manufactories of bows, bent felloes, shafts, sleigh runners, &c., and 2 tanneries. A large number of musket and rifle barrels are now made in the city, and a manufactory of cannon, rifles, muskets, swords, projectiles, &c., is about (April, 1862) to commence operations. The first settlement in the vicinity was made about 1680, and was named in 1720 in honor of Col. William Trent, speaker of the house of assembly. It was selected as the capital of New Jersey in 1790, and incorporated as a city

in 1792. On the night preceding Dec. 26, 1776, Gen. Washington crossed the Delaware river at McConkey's ferry, and attacked the Hessians, who were encamped in Trenton, surprising and routing them completely, taking about 1,000 prisoners, 6 brass field pieces, 1,000 stand of arms, and 4 standards. The Hessians numbered about 1,500, and 86 were killed in the skirmish, while the American loss was but 4. The force of the enemy in the vicinity being superior to Washington's, he returned to his camp on the other side of the Delaware on the night of the 26th. In 1788, Washington, while on his way from New York to Mount Vernon, was received with a triumphant welcome on the bridge over the Delaware at this place.

TRENTON FALLS, a post village of Oneida co., N. Y., on West Canada creek, 15 m. N. E. from Utica. It is principally noted for its falls, 6 in number, occupying at intervals a ravine 2 m. long, with an aggregate descent of 312 feet. The cascades are exceedingly beautiful. High walls of rock, sometimes reaching 150 feet, confine the stream, which is very rapid, through the greater portion of the falls. The village, a short distance below, contains a church, a large hotel, and about 20 houses. It is connected by railroad with Utica.

TRENTOWSKI, FERDINAND BRONISLAW, a Polish philosopher, born near Warsaw in 1808. He studied in Lukow and at the university of Warsaw, was for some time teacher of the Latin language and of Polish history and literature at the gymnasium of Szczecin, after the Polish revolution of 1830-'31 resorted to the German universities of Königsberg, Heidelberg, and Freiburg, and finally established himself as *Docent* at the last named place, making the German philosophy the subject of his critical examination. His principal writings, in German, Latin, and Polish, are: *Grundlage der universellen Philosophie* (1837); *De Vita Hominis Eterna* (1838); *Vorlesungen zur Wissenschaft der Natur* (1840); *Chowanna czyli system pedagogiki* (1842); *Stosunek filozofii do cybernetyki* (1843); *Myśli o życiu i o śmierci* (1844); and *Demonomania* (1844; 2d ed., 1854).

TREPAN, and TREPHINE (Gr. *τρύπανον*, to perforate), two surgical instruments used for removing portions of bone from the skull or other parts of the bony structure. The first was an instrument like a gimlet, to which was attached a crown or cylinder with saw teeth on its lower edge, and which was worked by a rotatory motion till it perforated the bone. Several different sizes of these cylinders were furnished by the instrument makers. The trephine is an instrument of later invention. Like the trepan it has a cylindrical saw, but no gimlet. A sharp steel point called a centre pin, which can be pressed into the bone until the saw has made a groove for itself, passes down the centre of the instrument, and is removable by the operator as soon as the groove is made. The cutting is accomplished, not as in the trepan by a rotatory movement, but by semi-rot-

tion, as in boring with an awl. The method of trephining is as follows: The point for the operation being determined, a crucial incision is made down to the bone, and the periosteum being dissected up, the trephine is applied, the centre pin being removed as soon as the track of the instrument is fixed, and the instrument itself raised every few strokes in order to see that it is not cutting through on either side, upon the tissues below. The greatest danger is when the circular piece is nearly separated; and some operators raise the cut portion by means of the elevator, rather than permit the instrument to divide it completely. The spicula of bone which may remain around the orifice are carefully removed by means of forceps. Trephining has been considered as indicated when there is a fracture of a portion of the skull, from a fall or blow with a blunt instrument, in order to elevate the depressed portion; in some cases of concussion, where there is reason to believe that the inner table of the skull is fractured at the opposite side of the head, and is producing irritation of the brain; in cases where extravasation of blood has taken place under the meninges of the brain from injuries or disease, or where purulent matter has accumulated under the meninges; in caries affecting the bones of the skull, the sternum or breast bone, or the tibia; and in some cases of a collection of purulent matter under the sternum. During the middle ages, in the "heroic" period of surgical practice, trephining was one of the most common operations of surgery, and thousands went to their graves with only a part of the bony covering of the brain which they originally possessed, and often died from inflammation of the membranes, the consequence of the empirical and careless use of the instrument. Of late years wiser views have prevailed, and the operation is now but seldom practised. Hey's saw, an instrument with a shaft and handle like a common steel fork, and having a plate of steel $1\frac{1}{4}$ inches in breadth and perhaps $1\frac{1}{4}$ in length attached to it, one edge of which is a straight and the other a convex saw, has almost entirely superseded it for most of those injuries of the skull which were formerly thought to require its use, greatly to the advantage of the patient. By this instrument the depressed portion is itself removed, instead of that which was not fractured, and the injuries to the skull can be remedied with far less loss of bony structure than under the old system.

TRESCHOW, NIELS, a Norwegian philosopher, born in Drammen, Sept. 5, 1751, died near Christiania, Sept. 23, 1833. He was the son of a merchant, and studied in the university of Copenhagen. After being a teacher in various schools, in 1803 he was appointed professor of philosophy in the university, and in 1818 in that newly founded at Christiania. In 1814 he was elected deputy to the storting, where he advocated the union of Sweden and Norway under one dynasty, and after the

union was appointed a state councillor and head of the department of public instruction and church affairs. He wrote "Morals for the People and the State," "Principles of Legislation," "Spirit of Christianity," and "Philosophical Testament, or Three Books of God, and of the World of Ideas and of Feelings, and of the Revelation of the former in the latter" 4 vols., Christiania, 1831-'3. He also translated the Gospel of St. John.

TRESPASS (Norman Fr. *trépasser*, from *trés*, beyond, and *passer*, to go), in law, as usually defined, a wrongful act, committed with some kind of violence, and injurious to the person, property, or rights of another. Its literal meaning is precisely the same as transgression; it is a step beyond the limits of law or right. In the old law Latin the word *transgressio* was used where trespass is used in English. Formerly the two words were employed in writing and conversation with the same meaning, but now trespass is commonly used only in the legal sense, and is an important law term. A familiar example of trespass may be found in an assault and battery, or a forcible entry into a house or upon lands, breaking open a door, or tearing down a fence. Such an act would be in law a trespass *vi et armis*, or, in the English phrase now used in indictments and declarations, a trespass with force and arms. Early in the history of the law a very slight degree of violence was sufficient to constitute this offence; and soon afterward the law held that it might be committed in some cases without any actual force whatever, implying by construction the force necessary to make it a trespass *vi et armis*, if the act were unlawful. Thus, for example, a peaceable entry into a house or land, with intent to take possession and oust the true owner, was regarded as a trespass *vi et armis*. Soon after there grew up a large and very important class of trespasses, where there was neither actual nor constructive force. The courts in fact invented a form of action, by means of which remedies might be given for a great number of injuries, to which the law of trespass with force and arms could not be made applicable by any construction. This new legal trespass was called, in the law Latin in use when the action was first employed, *transgressio super casum*, and is now called a trespass on the case. In the days of special pleading it had become a matter of great difficulty to determine whether the action by which redress was sought for in certain injuries should be trespass or trespass on the case; for if the plaintiff mistook his form of action, he wholly failed. In some of our states statutes were passed to meet the difficulty. At present, these statutes, with the rules of court and the amended practice, have taken away, if not the theoretical difficulty, at least its practical importance; for in most, if not in all of the states, at this time, if a mistake be made it may be corrected without delay and without cost.

Trespass with force and arms (or trespass alone, for the latter clause is often omitted) lies when the injury complained of is itself the wrong done by the defendant; while trespass on the case lies when the injury was consequential upon the wrong done, and flowed from it indirectly. For example, trespass on the case lies for an injury sustained by the plaintiff from the defendant's sale to him of unwholesome food, as meat or wine, especially where it was the business of the defendant to sell these things. So for an injury caused by the want of skill of any person in the exercise of his profession, as a physician or lawyer. There is yet another nice and very important distinction in the law of trespass. It is certain that a man may begin by doing a right thing in a right way, and then so change his course as to do a wrong thing, or a right thing in a wrong way. In many of these cases such a person thus subsequently trespassing is regarded by the law as a trespasser *ab initio*, or as having been a trespasser through the whole of his conduct. Thus, if, in the execution of a legal process, he does something which is distinctly illegal, the law considers that he began to act with intent to do an illegal thing, and that all of his conduct was tainted by this intention and was therefore illegal. Many cases have turned and much argument has been expended upon this distinction. We can only say that we consider that no man can be made a trespasser *ab initio* by a subsequent wrongful act, unless he did the wrong while in the exercise of a strictly legal right, which the injured party had no right to resist. Hence it seems to be confined by the best authorities to the cases of an officer of the law acting under a legal warrant, and a guest at an inn. It is extended to the latter, on the ground that a licensed innholder, being bound by law to receive a guest, and being subject to indictment if, without sufficient cause, he refuses to receive one, is then protected by the rule, that if the guest, thus exercising his positive right of entry peaceably and without offence, while in the house does a wrong to the innkeeper, the offender shall be held to have entered the house for that purpose, and therefore to be a trespasser from his entrance.

TREVES (Ger. *Trier*; anc. *Augusta Treverorum*), a town of Prussia, and the capital of an administrative district of the same name, in the province of Rhenish Prussia, situated on the right bank of the Moselle, 57 m. S. W. from Coblenz; pop. about 18,000, nearly all Roman Catholics. The river is crossed by a stone bridge of 8 arches, 690 feet long. The town stands in a fertile valley, surrounded by low vine-clad hills, and consists of the city proper and several suburbs. The former is about 1½ m. long, of oblong shape, surrounded by walls and entered by 8 gates. The cathedral is a very ancient building, and is supposed to have been originally erected by the empress Helena, who is said to have deposited there the seamless garment of the Saviour, now known as the

"holy coat of Treves." The exhibition of this garment in 1844 attracted 1,100,000 pilgrims, and brought large sums to the cathedral. The *Liebfrauenkirche*, or church of our dear Lady, built between 1227 and 1248, is a fine specimen of the pure pointed Gothic style. The church of St. Simeon, the most important Roman monument in Germany, was built as the gate of the city, between 814 and 882, and called *Porta Nigra*; and in the 11th century it was consecrated as a church. The ancient electoral palace, now occupied as a barrack, stands partly upon the site of a Roman edifice, a portion of which still remains with walls 90 feet high and 10 feet thick; it is supposed to have been the residence of Constantine the Great. The university, now called a gymnasium, was founded in 1454; it has a library containing 70,000 volumes and 2,000 manuscripts, among the latter of which is a *Codex Aureus* of the four Gospels. Treves is the seat of a Roman Catholic bishop. The manufactures consist of linen and woollen goods, leather, porcelain, &c. A considerable trade is carried on in all these articles, together with fruit and wine, which is greatly facilitated by the Moselle.—Treves is remarkably rich in Roman antiquities; among which, beside those above mentioned, are the bridge which crosses the river, the remains of the baths, and the amphitheatre. It was the favorite residence of several of the Roman emperors, and is described by the poet Ansonius as the second metropolis of the empire. It was almost totally destroyed during the invasions of the Goths, Vandals, and Huns, but afterward recovered; and in the times of the German empire, being the seat of archbishop-electors, who maintained large armies and possessed extensive territories and political power, it rose to great wealth and splendor. It was captured by the duke of Marlborough in 1704. During the wars consequent on the French revolution it suffered severely, and had its churches and convents plundered and converted into barracks, stables, and warehouses. Together with its electoral territories it was in 1799 annexed to France, the secularization of the archiepiscopal domains being soon after confirmed by the treaty of Lunéville. After the fall of Napoleon almost the whole former electorate, with its capital, was given to Prussia by the congress of Vienna.

TREVIRANUS, GOTTFRIED REINHOLD, a German naturalist, born in Bremen, Feb. 4, 1776, died there, Feb. 16, 1887. He was educated at the gymnasium of his native place, and at the university of Göttingen, took his medical degree in 1796, settled as physician in Bremen, and in 1797 became professor of mathematics in the lyceum of that city. His best works are: *Physiologische Fragmente* (2 vols., Hanover, 1797-'9); *Biologie oder Philosophie der lebenden Natur* (6 vols., Göttingen, 1802-'22); and *Erscheinungen und Gesetze des organischen Lebens* (2 vols., Bremen, 1831-'2).—LUDOLF CHRISTIAN, a German botanist, brother of the preceding, born in Bremen, Sept. 10, 1779.

He early began the study of the natural sciences, became in 1807 professor of medicine in the lyceum at Berlin, in 1812 ordinary professor of botany and natural history at Rostock, in 1816 professor of botany and director of the botanic garden at Breslau, and subsequently was transferred to Bonn, where he now holds the last named position. His principal work is his *Physiologie der Gewächse* (2 vols., Bonn, 1835-'9). He has also written *Vom inwendigen Bau der Gewächse* (Göttingen, 1806), and in 1855 published a treatise at Leipzig on the application of wood engraving to the delineation of plants. He also assisted his brother in his *Vermischte Schriften anatomischen und physiologischen Inhalts* (4 vols., Göttingen and Bremen, 1816-'21), and from 1824 to 1835 edited, with his brother and Tiedemann, the *Zeitschrift für Physiologie*.

TREVISO (anc. *Tureisium*), a fortified city of Austrian Italy, and the capital of a delegation of the same name in the government of Venice, situated on the river Sile, 20 m. N. N. W. from Venice; pop. about 20,000. The Sile is navigable for boats, and communicates by means of canals with the lagoons of Venice. Silk and cotton goods and cutlery are manufactured. A considerable trade is carried on in grain, fruit, and cattle; and an annual fair is held in October, which lasts 15 days. Treviso is the see of a bishop, and has several societies for advancing knowledge. It was a town of importance under the Romans, was made by the Lombards the capital of their two margraviates, became independent during the feuds between the Guelphs and Ghibellines, and in 1844 placed itself under the government of Venice, and has since that time shared her fate. In 1797 it was taken by the French under Mortier, who in 1808 received the title of duke of Treviso. In the summer of 1848 it was for a short time defended against the Austrians.

TRIANGULATION. See *SURVEYING*.

TRIBE (Lat. *tribus*), the term applied to the principal divisions of the Roman people. The Romans are said to have been divided by Romulus into 3 tribes, the Ramnenses, the Titienses, and the Luceres, respectively, it is believed, representing the Latin, the Sabine, and the Etruscan elements of the population, or rather of the patricians, who in the earliest period of Roman history constituted the state. Each tribe was subdivided into 10 *curia*, and was bound to furnish 1,000 men to serve on foot, and 100 horsemen, or *celeræ*, out of whom subsequently the order of *equites* or knights was formed. This arrangement was altered by the constitution ascribed to Servius Tullius, which admitted the plebeians to a share in political power, and divided the city into 4 and the surrounding country into 26 circles. About the middle of the 8d century B. C. the number of tribes had been augmented to 35 by successive additions, but no others were made

afterward. Though the number of tribes thus varied, that of the *curiæ* always remained the same, the relation of the latter to the former being modified.—In the Grecian states of antiquity, also, the people are frequently mentioned as divided into tribes (*phala* or *phalai*), which at an early period had the character of clans, and later mostly that of territorial or political divisions. There, where the people were of different races, not sufficiently blended together, the tribes frequently constituted classes distinguished by a difference of rights. They were subdivided into *phoroi* (fraternities), *genai* (*gentes*), &c. The Dorians were originally divided into 8 clans called Hyleis, Pamphyli, and Dymanats, and traces of this division can be discovered in the history of almost all the countries settled by them. The Ionians in Attica and elsewhere were divided into Teleontes or Geleontes, Hopletes, Argadenseæ, and Agicorenses. Theseus introduced a political division of the people into Eupatridæ (nobles), Geomori (agriculturists), and Demiurgi (laborers). The constitution of Solon preserved the original division into 4 clans, though considerably lessening its importance; that of Cleisthenes abolished it, creating 10 new tribes of a territorial character, subdivided into 100 *demi*. (See *DEMOS*).—For the tribes of Israel, see *HEBREWS*, vol. ix. p. 30.

TRIBONIANUS, a Roman jurist and publicist, who flourished during the reign of Justinian, died A. D. 545. Under Justinian he occupied the offices of *questor sacri palatii*, of *magister officiorum*, of prætorian prefect, and of consul. According to doubtful statements of Suidas, he is described as a man of great natural abilities and of wonderful learning, but avaricious, corrupt, and with great skill in flattery. In 528 he was one of the 10 commissioners selected by the emperor to form his first Codex, and in 529 was placed at the head of the committee of the most celebrated jurists of that time who were to compile the Digest or Pandects, which was finished and promulgated in 529. He at the same time, with two others, compiled the 4 books of the Institutes of Justinian, published in 529; and the second Codex of that emperor, published in 529, was also his work.

TRIBUNE (Lat. *tribunus*), literally, a Roman officer who presided over a tribe for certain purposes connected with its internal administration, or represented it in some other capacity. It is proper to remark, however, that some of the various officers to whom the name was applied exercised functions not included in this signification. Six kinds of tribunes are mentioned in Roman history, viz.: tribunes of the three ancient tribes, *tribuni celerum*, tribunes of the Servian tribes, tribunes of the people, military tribunes with consular power, and tribunes of the soldiers, whose offices were created nearly in the order here given.—The existence of a tribune or head of each of the three patrician tribes, the

Ramnenses, the Titienenses, and the Luceres, which originally comprehended the whole body of Roman citizens, is better established than the nature of the functions exercised by such officers, which, it may be said in general terms, included the direction of all civil, religious, and military affairs. They do not occur after the three tribes ceased to exist as political bodies.—The *tribunus celerum*, under the kings, was the commander of the 300 *celeres* or royal body guard, of whom 100 were taken from each tribe; and in the absence of the king, to whom he was next in rank, he convoked the senate and performed other royal functions. The office ceased with the overthrow of the kingly rule.—The tribunes of the Servian tribes were the administrative chiefs of the 30 local tribes into which Servius Tullius divided the Roman commonalty, and were originally charged with keeping a register of the inhabitants of their respective districts, and of their property, for the purpose of taxation. They are supposed by Niebuhr to be identical with the *tribuni avarii*, who in the later days of the republic acted as general inspectors and collectors of the *as militare* for the payment of the troops.—The tribunes of the people (*tribuni plebis*) were the most important of all the officers bearing the name; and to the influence which they exerted in checking the usurpations of the aristocratical element have been attributed the greatness of Rome and its long duration. They were first created after the secession of the commonalty to the Mons Sacer, in 494 B. C., as one of the conditions of its return to the city, and were empowered to afford protection to the plebeians against any abuse on the part of the patrician magistrates, for which purpose their persons were declared sacred and inviolable, and any attempt against their inviolability was made punishable by outlawry and forfeiture of property. They appear to have been originally two in number, and to have been elected for the term of one year by the comitia of the centuries; but as the latter were under the control of the patricians and their clients, the real advantage gained by the plebeians was at some time scarcely more than nominal, and it became evident that, in order to make the tribunes really the representatives and protectors of their order, they must be chosen by that order. It was not until several serious collisions had taken place between patricians and plebeians, owing to the systematic violation by the former of the prerogatives of the tribunitian office, that in 471 B. C. a law proposed by the tribune Volero Publilius, and since called the Publilian law, was passed, which the election of the tribunes was given to the comitia of the tribes. About the same time, or perhaps somewhat earlier, the number was increased to 5, and from the fall of the 2d decemvirate in 449 B. C. until the end of the empire 10 tribunes were annually elected. The tribunes being essentially the representatives and organs of the plebeian order, none

but members of that order were eligible for the office; so that if a patrician were desirous of filling it, he was obliged to qualify himself by becoming a plebeian. The early incumbents of the office exercised authority within the city limits and over one mile of adjacent territory; and in order that access might be had to them at all times, the doors of their houses were ordered to be open day and night, and all persons taking refuge there were assured of protection. For similar reasons they were forbidden to absent themselves from the city for a whole day. Although their lawful power was originally merely *auxilium*, or the right to afford protection, they assumed within a few years the right to convocate the senate, and in 454 succeeded, after a long struggle, in securing the appointment of the three commissioners whose labors led to codification of the laws of the 12 tables. During the 2d decemvirate the tribunate was suspended, but with the overthrow of that oligarchy it was restored with augmented powers; and as the tribes now included patricians and their clients as well as plebeians, the tribunes became the protectors of all classes of citizens. They now also acquired the right to be present at the deliberations of the senate, and to take part in its discussions, although not allowed to pass within the doors of the senate house; and hence they gradually assumed the privilege of intercession against any action taken by a magistrate, and by the interposition of their veto were enabled to annul any decree of the senate or stop any law, without cause or reason assigned. On the other hand, they sometimes interfered to compel the consuls to comply with decrees of the senate. In 180 B. C. they became senators by virtue of their office. They also added to their right of bringing patricians who had violated the rights of plebeians before the comitia of the tribes, that of commanding their *viatores* or attendants to seize a refractory magistrate, as a consul or a censor, and imprison him, or even to hurl him from the Tarpeian rock. Of equal importance was the power exclusively possessed by them, and frequently exercised without consulting the senate, of proposing *plebiscita* to the comitia of the tribes; and after these had obtained by the Hortensian law, 286 B. C., the binding force of laws, the tribunes became, as Niebuhr has observed, a magistracy for the whole Roman people in opposition to the senate and the oligarchical elements in general, although they had nothing to do with the administration of the government. One element of weakness, however, occasionally impaired the tribunitian power, which for upward of a century after the creation of the office had been exercised in accordance with the will of a majority of the college of tribunes. Subsequent to 394 B. C. the veto of a single tribune sufficed to render a resolution of his colleagues void; and it was not until Tiberius Gracchus introduced the practice of appealing to the people to remove

a tribune who obstinately adhered to his veto, that the harmonious working of the system was restored. During the latter period of the republic the tribunes wielded such enormous powers that Sylla in his reform of the constitution on an aristocratic basis gave them merely the *jus auxilii* which they originally possessed. Pompey restored them to their former power, but under the empire their privileges became much restricted, although until the 5th century of the Christian era they continued to have the right of intercession against decrees of the senate and on behalf of oppressed individuals. The emperors, though patricians, found it necessary to be tribunes, and the *tribunicia potestas*, conferred by the senate upon Augustus and his successors, was considered an essential part of the imperial dignity.—The office of military tribune with consular power originated in a compromise between the patricians and the plebeians, during the agitation of the project of C. Canuleius to open the consulship to both orders. The patricians consented that the consulship should be suspended, and that tribunes of the soldiers having consular powers should be elected in their stead indiscriminately from patricians or plebeians. In 444 B. C. three officers having this title were elected, and thenceforth until 366 the people were allowed to elect tribunes or consuls at their option. They varied from 3 to 6 in number, and had all the powers of consuls except that of censor, which was given to a new class of public officers.—Tribunes of soldiers were a class of military officers, of whom from 4 to 6 were attached to a legion. Originally they commanded the legion by turns, each holding office for two months, but subsequently they performed staff and administrative duties. Half of them were elected by the people, and half appointed by the consuls.

TRICHINOPOLY, a town of British India, capital of a district of the same name in the presidency of Madras, situated on the right bank of the river Cavery, in lat. $10^{\circ} 50' N.$, long. $78^{\circ} 44' E.$, 75 m. N. E. from Madura, and 190 m. S. S. W. from Madras; pop. 35,000. The fort of Trichinopoly is about a mile long and half a mile wide, built on the declivity of a granite peak about 600 feet high. On the top of the rock there are a citadel, a large pagoda, and some other Hindoo buildings. The walls of the fort are from 20 to 30 feet high and of great strength, and enclose a native town in which there are government stores, an arsenal, hospital, gaol, missionary chapel, &c. Outside the walls there are extensive barracks, hospitals, public rooms, a church and Roman Catholic chapel, and the tomb of Bishop Heber, who died here. The surrounding country is wonderfully fertile and populous; and the island of Seringham, which is here formed by the Cavery, is famous for the size and wealth of the Hindoo pagodas which it contains. Trichinopoly is the head-quarters of the southern division of the Madras army, and the garrison

generally consists of about 5,000 men, 1,300 of whom are British infantry and artillery. Cotton cloths, hardware, harness, cheroots, indigo, and jewelry are manufactured and exported to different parts of India and the Mauritius. Good roads connect Trichinopoly with Madras and all the surrounding districts.—Trichinopoly, after the death of its last rajah in 1732, fell into the power of the nabob of Arcot, and subsequently changed hands several times, figuring conspicuously in the contests of the French and English for supremacy in India. It finally came under English government with the rest of the Carnatic in 1801.

TRICOLOR, the name usually applied to the national banner of France, which consists of 3 colors, blue, white, and red, running in a direction parallel to the flag staff. It was adopted at the period of the first revolution, and owes its peculiar combination of colors, according to some authorities, to accident; although the liveries of Philippe Egalité, duke of Orleans, which were blue, white, and red, are also supposed to have suggested it. These colors, however, had been for many years previous used in combination as a national emblem, and were conferred upon the Dutch at their request by Henry IV., although in the flag of Holland they run in a direction at a right angle with the staff. They were successively employed in the French standards at different periods, viz.: the blue banner of St. Martin, the red or crimson of the oriflamme, and the white of the white cross, which was also the family color of the Bourbons. Since the French revolution tricolors, formed by the combination of any 3 colors, have been the favorite emblems of those engaged in liberal or revolutionary movements; and various European governments have arranged their national standards on a similar principle, as Belgium, Italy, &c. The national colors of Germany are those of the ancient empire, black, red, and gold.

TRIESTE (Ger. *Triest*; anc. *Tergeste*), the principal seaport of the Austrian empire, formerly capital of a governmental circle of the same name, and now of the crown land of Goritz, Gradisca, Istria, and Trieste, at the head of the gulf of Trieste in the N. E. of the Adriatic, 78 m. E. N. E. from Venice and 343 m. S. W. from Vienna (with both which cities it is connected by railway), in lat. $45^{\circ} 38' 50'' N.$ and long. $13^{\circ} 48' E.$; pop. in 1862, with its suburbs, 104,718. It is situated partly on level ground, and partly on the slopes of a hill whose summit is crowned by a citadel. It is divided into the old and new towns; the former occupies the southern and elevated portion, and has steep, zigzag, narrow, and dirty streets and blank walls. There are also numerous lofty, winding, labyrinthine flights of stone steps, with houses on both sides. Still it contains many broad streets and stately houses. The new town is separated from the old by a broad *corso* or avenue, and has wide straight streets, fine buildings, and numerous

public squares with fountains. The environs are very picturesque, the hillsides being built up in terraces and sprinkled with villas. The most notable hills behind the town contain numerous caverns hung with stalactites, which, before the railroad had made Adelsberg so accessible, were much visited. A wall surrounds the city. The Maria Theresa canal, large enough to admit vessels of ordinary size, penetrates into the heart of the new city. The most remarkable buildings are the cathedral of San Giusto, founded in the 5th century, in the Byzantine style, but injured by alterations made in the 14th century, the tower of which is said to stand on the foundation of a temple of Jupiter, which, with its crumbling Corinthian columns bound together by iron hoops, may be seen through arches cut in the tower; the church of St. Anthony, erected in 1830 at the head of the Maria Theresa canal; the Tergetseum, a splendid modern edifice comprising a bazaar, a fine concert and ball room, the exchange, the rooms of the Austrian Lloyd's, and the Casino Tedesco; the old exchange in the Piazza della Borsa, on which is a fountain and statue of the emperor Leopold I.; an opera house, and 8 theatres. Musical entertainments of a superior kind are given almost every evening; the annual musical festival in September is one of the finest in Europe. Beside the churches already mentioned, there are many others, including two Greek churches—one of the oriental, the other of the Serbo-Byzantine rite), an Anglican church dependent on the bishop of Malta, an Evangelical Lutheran church, and one of the Helvetic confession. This last occupies a small building which is said to stand on the foundation of the house of the martyrs Eugenia and Thecla, and to have been used as the first Christian church. The new lazaretto is one of the largest and best arranged in Europe. The railroad depot buildings are on a magnificent scale, the grounds covering 40 acres. This station, and those of Brignano and Nabrisina (where the road diverges, one branch to Venice and the other to Vienna), are supplied with water from the Aqueduct of the Romans, which, after a subterranean course, bursts from under the mountain into the gulf. The water is pumped up by steam to the height of 580 feet, and carried in iron pipes to its destination. There are also a custom house, post office, hospital, a large new poorhouse, barracks, governor's palace, and numerous schools. The public library of 80,000 volumes contains, among other things, a complete collection of all the printed editions of Petrarch, with all the books in all languages relating to him, and several fine manuscripts, one or two written by his own hand. In the same building, which contains also the imperial naval school, is a museum of natural history. There are also a botanic garden, a public garden, and a fine grove of oaks on the steep declivity of a hill laid out in gravel walks and open to the public. The archduke Maximilian's

beautiful villa of Mira Mare with its fine grounds is open to visitors, and a road 5 m. in length along the shore of the gulf has been constructed for that purpose. The grounds of several other villas not far from the city are also open to visitors. Several merchants and bankers have fine collections of paintings and statuary. Near the cathedral is an enclosure containing a large collection of Roman monuments, to which additions are constantly made. In this enclosure is the tomb of Winckelmann, who perished at Trieste by the hand of an assassin. There are 6 newspapers published, of which 4 are in Italian, one in German, and one in Greek.—The harbor is small, but very good, being protected on all sides except the N. W. It is deep enough for vessels of 800 tons to come up to the quays, and for those of any draught except the very largest to ride at anchor. It is in crescent form, and the S. W. horn is formed by the Theresa mole, which terminates in a fort and lighthouse, and encloses a large quarantine anchorage ground. There are extensive ship-building docks near the harbor. The trade has steadily increased since it was made a free port by the empress Maria Theresa, in the middle of the last century, and is now very large. Its principal exports are grain, rice, wine and liqueurs, oil, flax, hemp, tobacco, silk, wool, wax, marble, iron, lead, quicksilver, copper, alum, vitriol, silk stuffs, glass, leather, soap, printed cottons, and coarse and fine linens. The imports comprise cotton, silk, dye-stuffs, hides, raisins, Odessa wheat, rice, oil, and fruits and produce from the West Indies, Brazil, and the United States. The value of the imports in 1850 was \$17,485,728; in 1855 it had fallen to \$12,406,024, but in 1859 had increased to \$66,342,773, and in 1860 to \$72,102,440, of which amount \$2,693,298 was from the United States. The exports in 1859 amounted to \$56,491,949, and those of 1860 to \$60,562,547, including \$583,275 to the United States. The arrivals in 1860 were 10,243 vessels, tonnage 717,296, of which 963 were steamers, tonnage 252,212; the departures were 10,822, tonnage 736,078, of which 959 were steamers, tonnage 251,780. Of these more than $\frac{3}{4}$ were under the Austrian flag. The Austrian Lloyd's steam packet company, formed in 1833, has 40 or 50 steamers plying between Trieste and the principal ports of the Adriatic, the Levant, and the Black sea. Trieste, though notable mainly for its commerce, has considerable manufactures. Beside the ship building already noticed, there are manufactories of earthenware, leather, wines, spirits, soap, playing cards, and musical instruments, sugar refineries, tanneries, and dye houses. The people are of various races, Italians, Slavi, Greeks, Germans, Jews, &c. There are many foreign commercial houses in the city. The climate is variable, and subject to sudden changes owing to the alternate prevalence of the hot and oppressive sirocco and the cold and cutting *bora*; but in the winter and spring

it is oftenest calm.—Tergeste was a city prior to the Roman conquest, which took place in 179 B. C. Augustus fortified and surrounded it with walls. It escaped the invasion of Attila by which Aquileia was destroyed, and passed under the dominion of the Ostrogoths, and afterward of the Greek emperors, till the period of the Lombard invasion. Subsequently Trieste became independent under its bishop, who bore the title of count, and who gradually sold to the inhabitants the privileges of a free city. Long wars ensued with the patriarchs of Aquileia, who as margraves of Istria claimed the allegiance of the bishops of Trieste, and in these wars Venice and Genoa also took part. The peace of Turin in 1381 acknowledged Trieste as an independent city, and the next year the citizens voluntarily submitted to the house of Austria. Charles VI. declared it a free city in 1719, and Maria Theresa made it a free port in 1750. It was taken by the French in 1797 and again in 1805. From 1809 to 1814 it belonged to the French province of Illyria, and subsequently, till 1850, to the Austrian kingdom of that name.

TRIGG, a S. W. co. of Ky., bordering on Tenn., bounded W. by the Tennessee river and drained by the Cumberland and Little rivers; area, 530 sq. m.; pop. in 1860, 11,052, of whom 3,449 were slaves. The surface is hilly and the soil fertile in parts. The productions in 1850 were 604,515 bushels of Indian corn, 87,090 of oats, and 1,653,485 lbs. of tobacco. There were 18 churches, and 681 pupils attending public schools. Horses, cattle, mules, and swine are raised and exported in great numbers. Iron, bituminous coal, and limestone are found. Capital, Cadiz.

TRIGONOMETRY, that branch of mathematics which undertakes to compute the unknown elements of triangles when certain other elements are given. It is called plane when it considers triangles which lie wholly in a plane surface, and spherical when it considers triangles formed in the surface of a sphere by the intersection of 3 great circles, that is, circles whose plane passes through the centre of the sphere. Of the 6 elements (3 sides and 3 angles), 3 must always be given for the determination of the rest. The angles are not employed as in geometry, but in their stead certain functions of them called the sine, cosine, tangent, cotangent, &c. These functions have been calculated for all acute angles and arranged in logarithmic tables. To explain them briefly: consider a plane right-angled triangle, *abc*, in which *ac* represents the hypotenuse; $\frac{bc}{ac}$ will express the sine of the angle at *a*, and likewise the cosine of the angle at *c*; $\frac{bc}{ab}$ will express the tangent of the angle at *a*, and likewise the cotangent of the angle at *c*. If the hypotenuse be taken as unity, *bc* will express the sine and *ab* the cosine of the angle at *a*; from which it appears that the sine of an acute angle will in-

crease, and its cosine diminish, as the angle increases; at 90° the sine reaches its maximum or unity, and the cosine its minimum or zero. For acute-angled plane triangles the following propositions are of leading importance: 1, any two sides of a triangle have to each other the same ratio as the sines of their opposite angles; 2, the sum of the two sides of a triangle is to their difference, as the tangent of half the sum of the angles lying opposite them is to the tangent of half their difference.—For the application of trigonometry to surveying see COAST SURVEY, and SURVEYING.

TRILL, or SHAKE, in music, an embellishment consisting of the alternate reiteration of two adjoining notes, the lower of which, being the chief or essential tone, is marked with the character *tr*. It comprehends an interval not greater than a whole tone nor less than a semitone, and is generally commenced with the upper or assistant note, ending with the lower. Both notes should be distinctly heard, and the interval carefully preserved.

TRILLIUM (Lat. *trilis*, triple), a genus of North American herbaceous perennial plants of the natural order *smilacaceae*, and much admired either when wild or under cultivation. About 12 species are enumerated as occurring in the United States, all having a general resemblance. The stem is simple, arising singly from a short tuber-like rootstock, which is stout, from 3 to 8 inches high, bearing on its summit 3 broadly ovate leaves and a terminal flower consisting of 3 lanceolate, persistent, spreading sepals, 3 larger petals which wither as the flower advances, 6 stamens with linear anthers, the styles consisting of 3 awl-shaped processes spreading above and persistent, the inner surfaces being stigmatic, succeeded by an ovate, angular, 3-celled, purple or crimson berry, containing several seeds affixed horizontally in each cell. The finest for the flower border is the large white trillium (*T. grandiflorum*, Salisbury), having large dark green foliage and very conspicuous white petals, changing to rosy pink just before they wither. It is found in forests from Vermont to Wisconsin and northward, and increases rapidly under cultivation both from its seeds and multiplication of its roots. A smaller species, appearing in April with its pretty white flowers, is the dwarf trillium (*T. nivale*, Riddell), found in Ohio and Wisconsin. The painted trillium (*T. erythrocarpum*, Mx.) has oval, pointed, vary white petals, which are striped with purple lines at their base. It grows in cold damp woods from New England northward, and in portions of the Alleghanies of Virginia. The birthroot (*T. erectum*, Linn.) is a conspicuous plant with broad, rhomboidal, and abruptly pointed leaves, and ovate, spreading, dark purple petals, which sometimes are greenish white or yellowish when it becomes the variety *album* of Pursh. They grow together in rich woods of New England and New York, northward and westward. The root affords a violent emetic. *Ab-*

other species is the *T. sessile* (Linn.), with its leaves and flowers sessile, the petals dull purple varying to greenish, found from Pennsylvania to Wisconsin and southward. Its root has similar medicinal properties. Two or three species are particularly southern, and have rose-colored petals. The drooping trillium (*T. cernuum*, Linn.) has clustered stems, 2 or 3 together, broadly rhomboidal leaves, and small, acute, wavy, recurved, short, white-petalled flowers, concealed by the curved peduncle beneath the leaves. Its distribution is very wide from New England southwardly. —A blue coloring matter can be procured by treating the juice of the ripe berries of the trillium with alum, and the general medicinal properties of the species are emetic.

TRILOBITE (Gr. *τρεῖς*, three, and *λοβος*, lobe), the name of a group of fossil crustaceans, so called from the 3 lobes into which the body is divided; they form the *palæada* of Dalman and the *branchiopodaires* of Milne-Edwards. They were once supposed to be mollusks with 3-lobed shells and a fleshy gasteropodous foot, but are now known to be articulates; they do not correspond exactly to any living group, but, according to Burmeister ("Organization of Trilobites," Ray society's publications, 4to., London, 1846), were a peculiar family of crustaceans, nearly allied to the existing *phyllopoda* (like *apus* and *branchipus*), and forming a connecting link between these and the *pacilopoda* (like *argulus*, *caligus*, and other parasites called fish lice); they come nearest to *phyllopoda*, especially in the double large eyes, undeveloped antennæ, and soft membranous feet, and nearest of all to *branchipus*; a marked resemblance in the form of the *limulus* (king-crab, or common horseshoe of our coasts) is also observed to that of many species of trilobites. The general form of the animal is oval, divided into 3 well defined regions, the head or buckler, the thorax, and the abdomen or *pygidium*, the last 2 composed of semicircular plates or segments, varying in number, by whose movements the animal could roll itself into a ball like the common wood louse and pill bug (*oniscus* and *armadillo*). Each of these 3 divisions presents 3 lobes limited by 2 longitudinal depressions; the head is generally the largest and considerably the widest, varying from $\frac{1}{2}$ to $\frac{1}{3}$ the total length, semicircular, with a border often ornamented with granulations, depressions, and spines; the middle portion is the *glabella*, the grooves which mark its lateral limit corresponding, according to Barrande (*Système silurien de Bohême*, 4to., Paris, 1858), to the insertion of the jaws or first pair of feet; the different pieces are united by distinct sutures, which are important zoological characters. Eyes were denied to some genera, *conocephalites* being the only one in the primordial fauna in which these organs are certainly known to have been present; some had eyes when young, but lost them when old; others had 2 well formed, compound, faceted,

prominent eyes, which are often perfectly preserved in the fossil state; they are sometimes larger than half the length of the head, the greatest diameter being almost always the longitudinal; they had no simple eyes. Traces of a mouth have been distinguished in a few; no traces of antennæ have been found, and they were probably short and feebly developed. The number of the thoracic segments varies in different genera, and at different stages of growth, but is constant in adults of the same species; the terminal portions on the sides are the *pleurae*, and are curved backward and sometimes very long; no traces of feet have been discovered, but they were doubtless soft, membranous, and leaf-shaped, as in *phyllopoda*. The *pygidium* was made up of segments like those of the thorax, but consolidated to form a posterior buckler; it was usually semicircular, less long than wide, developed inversely to the thorax, and the largest in the more recent genera. The shell had a thinner horny membrane covering it, becoming more delicate toward the median line; between the two is found in the fossils a stony layer measuring their distance from each other; the lower surface was soft and membranous; the skin was undoubtedly cast as in other articulates, and Wahlenberg has suggested that some supposed new species may have been founded on their cast shells. They have been divided into 3 families, according to the nature of their covering: 1, *eurypterida*, without shell, including the single genus *eurypterus* (De Kay); 2, *cytherinida*, with bivalve, bean-shaped shell, including the single genus *cytherina* (Lam.); and 3, *trilobita*, with a shell having as many rings as there are joints to the body, containing many genera and species, and divided into 3 large groups, one with the power of rolling into a ball, like *ogygia* (Brongn.), and the other with no such power, as in *calymene* (Brongn.); the first are found chiefly in limestone strata, and are less ancient than the second, which occur principally in the lowest silurian rocks. According to Burmeister, the trilobites moved only by swimming, just below the surface of the water, with the back downward, rolling into a ball when danger threatened from above, and did not creep upon the bottom; they lived in shallow water, near the coast, associating in immense numbers, chiefly of the same species; while only 6 or 8 species occur in a given stratum, the number of individuals was very great; their food consisted of small aquatic animals and their spawn; they underwent progressive metamorphoses, and varied considerably according to age; their metamorphoses are given at length by Barrande, who makes 4 distinct types, according to the serial development of the different parts.—Trilobites are the oldest of the articulates, and among the first created animals on this planet; though none are now living, during the palæozoic period they were very abundant, and almost the only representatives of their class.

They have been most studied in Bohemia, and by M. Barrande. There are none found above the carboniferous rocks, and only one genus (*Phillipsia*), according to Pictet, in that; Barrande's primordial fauna, or the lower silurian, has one genus but no species passing to his second fauna or middle silurian, and this has many genera but no species common to it and the third fauna or upper silurian, which in turn has several genera passing to the devonian fauna—the whole series affording remarkable proofs of the limitations of faunae in time; their distribution in space was also very circumscribed, probably on account of their feeble locomotive powers. In America several trilobites, especially *paradoxides* and its allied genera, have been met with in slates formerly classed among the metamorphic rocks, as the *P. Harlani* (Green), found in Braintree, Mass., in 1856, by Prof. W. B. Rogers, and this and other trilobites in Canada and Newfoundland.—The trilobites have long attracted much interest, as well on account of the great numbers in which they have been found in many localities, as from their singular conformation, and the perfect state in which their forms are preserved. They were noticed in the "Philosophical Transactions" for Aug. 1698, and Burmeister, in his work referred to above, cites 98 authors whose writings he has examined on this subject. The eye is a feature of great beauty in this animal, and its perfection in many of the stony fossils, especially some brought from the Hartz mountains, and from the upper silurian limestone of Dudley, England, is very remarkable; the facets or lenses, sometimes nearly 400 in number, are like those observed in the eye of the dragon fly and butterfly, and as in these insects are arranged around a conical-shaped tube through which the visual rays enter from almost every direction; in the *asaphus caudatus* each eye thus has a range of nearly $\frac{1}{4}$ of a circle, and both together command a panoramic view. Buckland in his "Geology and Mineralogy considered with reference to Natural Theology," vol. i. p. 870 (London, 1858), avails himself of this interesting feature, so perfectly developed in the most ancient periods of organic life, to draw an argument of the identity of mechanical arrangements existing through the long succession of animated beings down to the present time, and hence of the continuance of the same intelligent creative power. The structure of the eye also indicates the prevalence in those ancient periods of the same conditions of the waters and the atmosphere, as regards their adaptation to the organs of vision, as now obtain; and it affords a strong argument against the theory of a gradually advancing development in animal structures in the progress of geological periods.—The geographical range of trilobites is very extensive; these fossils are met with at most distant points, both of the southern and northern hemispheres; they are found all over northern Europe, and in numerous localities in North America, in the

Andes of Bolivia, and at the Cape of Good Hope. Trenton Falls, N. Y., has afforded, in the limestone known by its name, fine specimens of the species *calymene Blumenbachii* (Brongn.). Lebanon, Ohio, is another interesting locality. In Adams co., Ohio, Dr. Lock procured an *isoletus*, to which he gave the specific name *megistos*, that measured more than 20 inches in length and 12 in width. The *isoletus gigas* (De Kay) and *paradoxides Harlani* have been found 12 inches long.

TRIMBLE, a N. co. of Kentucky, bordering on the Ohio river; area, 150 sq. m.; pop. in 1860, 5,880, of whom 881 were slaves. The surface is generally hilly and the soil fertile. The productions in 1850 were 284,795 bushels of Indian corn, 19,516 of wheat, 80,754 of oats, and 454,722 lbs. of tobacco. There were 14 churches, and 820 pupils attending public schools. Capital, Bedford.

TRIMMER, SARAH, an English writer of juvenile and educational works, born in Ipswich, Jan. 6, 1741, died Dec. 15, 1810. She was the daughter of Joshua Kirby, author of "The Perspective of Architecture," and subsequently tutor in perspective to George III. then prince of Wales, and at the age of 21 was married to Mr. Trimmer. About 1750 she began her literary career with an "Easy Introduction to the Knowledge of Nature," and from 1782 to 1784 appeared 6 volumes under the title of "Sacred History, selected from the Scriptures, with Annotations and Reflections, adapted to the Comprehension of Young Persons." In 1786 she published the "Economy of Charity," of which a revised and enlarged edition appeared in 1801. She also edited the "Family Magazine," designed for the instruction of the lower classes, and subsequently carried on a periodical work called the "Guardian of Education." She wrote books for the use of charity schools, which received the sanction of the society for the promotion of Christian knowledge. In 1806 she published a "Comparative View of the New Plan of Education," which caused much controversy by the views it took of the education of the poor. An "Account of the Life and Writings of Mrs. Trimmer" was published in 1814 (2 vols. 8vo.).

TRINCOMALEE, a town of Ceylon, situated in the S. E. part of the island, in lat. 6° 33' N., long. 81° 14' E.; pop. about 20,000. It stands on the N. side of the entrance to a capacious and secure harbor at the foot of well wooded hills, and two heights crowned by forts, beside which the port is defended by numerous fortifications which extend for about a mile along the shore. The inner harbor is landlocked, and has water in many places sufficient to float the largest vessels close to the shore; but its peculiar superiority over all other harbors of India consists in its being accessible to all descriptions of ships during both monsoons. The inhabitants are mostly Tamulians and their descendants, from the S. E. coast of India. The trade is of little importance, but a consid-

erable quantity of precious stones are found in the neighborhood. The Portuguese were the first European nation that formed a settlement at Trincomalee. They were expelled by the Dutch, who held the place till 1782, when they were in turn driven out by the British; but an insufficient garrison having been left for its defence, it was captured by the French, who restored it to the Dutch. In 1795 the British again captured it after a siege of three weeks, and it has since then remained in their possession and been their chief naval station in the Indian ocean.

TRINIDAD, one of the British West India islands, situated at the mouth of the gulf of Paria, off the N. E. coast of Venezuela, opposite the N. mouth of the Orinoco, between lat. 10° and 11° N. and long. 61° and 62° W.; length N. and S. about 50 m., average breadth 30 m.; area, about 2,400 sq. m.; pop. in 1851, 68,645. Its S. W. and N. W. extremities approach to within 7 and 13 m. respectively of the continent of America. There is excellent anchorage in many places between Trinidad and the mainland, beside which there are several good harbors on the other sides of the island. It is crossed by three ranges of hills from W. to E.; the highest borders the N. coast, and attains an elevation in places of 3,000 feet; the second range is from 600 to 1,000 feet high, and occupies the centre of the island; while the third, of about the same elevation, stretches along the S. coast. There are in some places level and undulating tracts in the valleys between these ranges, but in others the surface is considerably broken. Both valleys are drained by rivers with numerous tributaries. Much of Trinidad is alluvial, and appears to have been formed by the mud deposited by the Orinoco. The mountains consist of clay and mica slate; and quartz, pyrites, arsenic, alum, sulphate of copper, graphite, and sulphur are all found. In a volcanic district on the W. coast there is an asphaltum lake, 150 acres in extent and of unknown depth. At the side next the interior of the island it is cold and firm, and rent into chasms from 8 to 30 feet wide; but toward the sea it is liquid and in a state of slow ebullition. Traces of volcanoes appear in several parts of Trinidad; bitumen is thrown by the sea upon the shore in the neighborhood of the lake, and there is an active mud volcano at the extremity of the S. promontory. At Port of Spain, the capital, the temperature ranges between 74° and 86° in summer, and 70° and 81° in the coldest months. The fall of rain is 65 inches during the year; the island is beyond the range of hurricanes; slight shocks of earthquake are sometimes felt. A great deal of the soil is fertile, and the elevated parts of the island are covered with dense forests. The chief productions are sugar cane, coffee, and cacao; and cotton, indigo, tobacco, nutmegs, cinnamon, cloves, &c., are raised in small quantities. The indigenous animals are two species of small deer, the opossum, armadillo, para, porcupine,

ant-bear, sloth, muskrat, tiger cat, two species of lizards, and numerous monkeys. Fish are abundant. The settlements are chiefly upon the N. W. coast and in the adjacent valley. A considerable trade is carried on with the United States in lumber and provisions. The public affairs of Trinidad are administered by a lieutenant-governor, assisted by executive and legislative councils. The island was discovered by Columbus in July, 1498, was taken possession of by the Spaniards in 1598, captured by the French in 1676, but soon restored to the Spaniards, and was finally taken by the British from the latter in 1797.

TRINITY (Lat. *trinitas*), the name which, in the theology of the Roman Catholic, the eastern, and most of the Protestant churches, denotes the nature of the Divine Being, attributing the one divine substance to three persons (Father, Son, and Holy Ghost), so that all the three are one God as to substance, but three persons as to individuality. Those who accept this doctrine are called Trinitarians, those who reject it Anti-Trinitarians or Unitarians. The word Trinity occurs neither in the Old nor New Testament. It is allowed by Trinitarians that no passage of the Old Testament can be adduced which would show that the doctrine of the Trinity was known to the Israelites, but many passages are claimed as proving the belief of the Israelites in a plurality in the Godhead. Each of these texts, however, has been interpreted in a different manner by Trinitarians themselves. From the New Testament two large classes of texts are quoted as arguments for establishing the doctrine of the Trinity: those in which Father, Son, and Holy Spirit are mentioned in connection, and those in which these three subjects are mentioned separately, and in which their nature and mutual relation are more particularly described. The term Trinity (Gr. *τριάς*) was introduced, after the example of Platonic philosophers, by Theophilus of Antioch, in the 2d century, and was afterward often used by Origen in the 3d century. Among the Latin ecclesiastical writers, Tertullian was the first to use the term *trinitas*. There was an almost uninterrupted controversy about this doctrine in the ancient church, and a number of views were proscribed by the church as heretical. Among them were those of the Ebionites, who regarded Jesus as a mere man; of the Sabellians, according to whom the Father, the Son, and the Holy Ghost were only the different forms in which the one God reveals himself to men; of the Arians, who taught that the Son was not coeternal with the Father, but created by him before the creation of the world, and therefore subordinate to the Father; of the Macedonians, who denied the personality of the Holy Ghost; and many others. The doctrine of the church was fixed by the councils of Nice (325) and Constantinople (381), which declared that the Son and Spirit were coequal with the Father in the divine unity, that the Son was eternally begotten by the

Father, and that the Spirit was proceeding from the Father. The western church, at the synod of Toledo (589), declared that the Holy Ghost proceeded also from the Son (*filiusque*); but the Greeks protested against this change of the creed as an innovation, and the phrase *filiusque* has remained up to the present day one of the chief hindrances of a reunion between the Greek and the Roman Catholic churches. The symbolic books of the Lutheran and Reformed churches retained the Roman Catholic doctrine of the Trinity unchanged; but it has been attacked ever since the 16th century, as contrary to both the Bible and sound reason, by a large number of theologians and by several new denominations, as the Socinians, the German theosophists (Weigel, Boehm, &c.), the Unitarians, and the Universalists. Swedenborg referred the Trinity to the person of Christ, teaching a trinity, not of persons, but of the person, by which he understood that that which is divine in the nature of Christ is the Father, that the divine which is united to the human is the Son, and the divine which proceeds from him is the Holy Spirit. The spread of rationalism in the Lutheran and Reformed churches undermined for some time the belief in the Trinity among a large portion of German theologians. Kant thought that Father, Son, and Spirit designated only three fundamental qualities in the Deity, power, wisdom, and love, or three agencies of God, creation, preservation, and government. Hegel and Schelling attempted to give to the doctrine of the Trinity a speculative basis; and after their example the modern dogmatic theology of Germany has in general undertaken an apology of the doctrine of the Trinity on speculative as well as theological grounds. A number of supranaturalist theologians, however, do not hold the strict doctrine of ecclesiastical orthodoxy, as defined by the councils of Nice and Constantinople, and the view of Sabellius especially has found in modern times many advocates.—Complete and exhaustive works on the history of the doctrine of the Trinity have been published by Baur (*Die christliche Lehre von der Dreieinigkeit*, Tübingen, 1841), and Meier (*Die Lehre von der Trinität in historischer Entwicklung*, Hamburg, 1844).

TRINITY. I. An E. co. of Texas, formed since 1860, bounded N. E. by the Neches and S. W. by the Trinity river, and drained by several creeks; area, about 700 sq. m.; pop. in 1860, 4,892, of whom 959 were slaves. The surface is nearly level, and the soil fertile. Corn and cotton are the staples. Capital, Sumter. II. A N. W. co. of California, bounded E. by the Coast range, and drained by tributaries of Trinity and Eel rivers; area, about 8,000 sq. m.; pop. in 1860, 5,125. The surface is generally hilly, and in the E. part mountainous, containing Mt. Linn, the highest peak of the range. The productions in 1858 were 19,060 bushels of wheat, 25,170 of barley, and 4,660 of oats; and in 1856 there were returned 1,228 tons of hay

and 169,150 bushels of potatoes. There were 4 grist mills and 18 saw mills. Gold mining is largely prosecuted, and other valuable minerals are found. Capital, Weaverville.

TRINITY. I. A river of Texas, formed by two streams, called the West fork and Elm fork, which rise near the N. boundary of the state, and after a length of about 150 m. each unite in Dallas co., whence the main stream flows in a tortuous but generally S. S. E. direction to the N. extremity of Galveston bay, about 40 m. from Galveston city. Its whole course lies through a valley of great fertility, occupied in part by extensive plantations of corn, cotton, rice, and sugar; but the greater part is still unoccupied and unexplored. The length of the main stream is about 550 m., and steamboats ascend from 350 to 500 m. in time of high water, the stream being principally fed by rains, which are abundant from February to May. II. A river of California, rising by two forks near the Coast range in Trinity co., about lat. 40° 30' N., and flowing S. W. and then N. W. into the Klamath river in lat. 41° 20' N. It is celebrated for its rich gold mines.

TRINITY COLLEGE, an institution of learning at Hartford, Conn., under the control of the Protestant Episcopal church. Its charter was obtained in 1823, under the name of Washington college, and an endowment of \$50,000 subscribed within a year; the college buildings were commenced in 1824, and the college regularly organized and recitations held in the autumn of the same year. Its first president was the Rt. Rev. Dr. Thomas C. Brownell, bishop of Connecticut, who resigned in 1831 and was succeeded by the Rev. N. S. Wheaton, D.D. In 1837, on his resignation, the Rev. Silas Totten, D.D., was elected president, and during his administration, in 1845, its name was changed to Trinity college. He was succeeded in 1848 by the Rev. John Williams, D.D., now assistant bishop of Connecticut, who in 1853 resigned, and the Rev. Daniel E. Goodwin, D.D., previously professor of modern languages in Bowdoin college, became his successor. In 1860 Dr. Goodwin was elected provost of the university of Pennsylvania, and the present incumbent, Samuel Eliot, then professor of history, was chosen president. At different periods of its history the college has received endowments amounting to about \$150,000, of which \$16,000 has been contributed by the state and the remainder by its friends. Among its professors have been Dr. S. F. Jarvis, in the chair of oriental literature; Bishop Horatio Potter, in that of mathematics and natural philosophy; Bishop Doane in that of rhetoric and oratory; Charles Davies, LL.D., in that of mathematics; Thomas W. Coit, D.D., in that of ecclesiastical history; George O. Shattuck in that of institutes of medicine; and the Hon. W. W. Ellsworth in that of law. In 1861 the number of professors and other instructors was 14, of alumni 500, and of students 70; and the libraries comprised 18,500 volumes.

TRIO, a musical composition for 3 voices or instruments, one of the parts of which must make a third with the base and the other a fifth or octave. In a minuet it signifies the passage, formerly called the *menuetto*, which alternates with the minuet proper.

TRIPANG. See *SEA CUCUMBER*, vol. xiv. p. 467.

TRIPOD (Gr. *tripes*, three, and *pous*, a foot), literally, any vessel, table, seat, or other utensil supported on 3 legs. The term is most commonly applied to the bronze chair or altar in the temple of Apollo at Delphi, on which the Pythian priestesses sat while giving responses to those consulting the Delphic oracle. Numerous imitations of the Delphic tripod were employed in the worship of other deities, particularly Bacchus, in games celebrated in honor of Apollo, at which it was often given as a prize, and on similar solemn occasions; and in domestic use it assumed many graceful variations of the original form. Tables, caldrons for boiling food, and *crateres*, or vessels in which wine was mixed with water at the banquets of the ancients, were frequently tripods richly ornamented. Fine specimens have been exhumed at Pompeii.

TRIPOLI (called by the natives *Tarabul*), a country of N. Africa, forming one of the Barbary states, nominally dependent on the Turkish empire, bounded N. by the Mediterranean, E. by the state of Barca, S. by Fezzan and the desert of Sahara, and W. by the Sahara and Tunis, between lat. 28° and 33° 30' N., and long. 10° and 20° E.; extreme length about 800 m., breadth from 100 to 200 m.; area estimated at 105,000 sq. m.; pop. 1,500,000. Though the sea coast extends 800 m., there is only one good harbor, that of Tripoli, in its entire length. In its E. part, between Cape Mesurata and the town of Bengazi, there is a remarkable indentation called by the ancients Syrtis Major, now the gulf of Sidra or Sert. (See *SYRTIS*.) The shore to the W. of Cape Sciarra is low and sandy; but to the E. it becomes higher, and has many rocky points that afford shelter to small craft, and there is good anchorage in the bay of Bushaifa in 6 fathoms water. The soil is exceedingly porous, and most of the streams only flow during the rainy season. The interior of the country is very imperfectly known. The N. E. part contains extensive tracts of barren sand, and partakes of the nature of the desert; but the S. E. is traversed by the Black mountains, an offset of the Atlas, which descend in terraces enclosing several fertile tracts. Toward the W. the surface becomes diversified, and is traversed by two ranges of mountains, which run nearly parallel with the sea, the N. range about 20 m. from the shore, and the S. 80 m. further inland. The former has a general height of about 4,000 feet, and is visible from the coast. These mountains are of volcanic origin, and many of the summits terminate in conical peaks. The space between the ranges contains many tracts of elevated

table land, with a fertile soil produced by the decomposition of lava and basalt. Salt and sulphur are the only minerals known to be worked. Some of this land is carefully cultivated, and irrigated with water collected for the purpose in large tanks. Abundant crops of grain are raised, and on the sides of the hills vines, olives, figs, almonds, and other fruits grow luxuriantly. There are extensive natural pastures upon which cattle are reared in great numbers. The most fertile part of Tripoli, however, is the country which surrounds the capital. This tract, called the Mesheea, extends about 15 m. along the shore, and is about 5 m. broad, and produces heavy crops of wheat, barley, millet, and Indian corn. Palm trees and olives are grown, together with all kinds of fruit that can be produced in a temperate climate. The country which lies S. of the table land contains very little productive land. In places it consists of a plain of loose sand, and in others of gravel from which the sand has been swept by the wind, while there are places covered with detached stones, and a few spots have stunted bushes. The water, which is only found by digging from 100 to 200 feet, is bitter and brackish. In the few spots where barley and durra can be raised there are villages, the inhabitants of which live in constant dread of the wandering tribes of the adjacent desert. Heavy rain falls in the N. part of the country from November to March, but during the rest of the year months often pass without a single shower, and the heat becomes very great, especially when the sirocco blows. In winter the weather is exceedingly variable, and frosts occur at night, while the temperature during the day often exceeds 70°. The horses of Tripoli are of a very superior breed, and cattle are numerous on the table land. Camels are extensively used as beasts of burden, and sheep and poultry are exported. Of wild animals the most common are wolves, foxes, hyænas, jackals, gazelles, antelopes, rabbits, hares, hedgehogs, jerboas, and a small animal not unlike a Guinea pig, called *gundy*. Ostriches frequent the borders of the deserts; and most of the birds common to the neighboring countries are found in Tripoli. Swarms of locusts frequently come from the Sahara, and are eaten with great relish by the poor; they are salted in large quantities, and appear to constitute an important article of inland trade. There are many bees in the hilly regions.—Tripoli contains numerous remains of antiquity; and there are ruins of temples, theatres, and aqueducts of Roman construction. Many of these ruins have been buried deeply in sand; but they can still be traced in the city of Tripoli, and in Tripoli Vecchia, where there is an amphitheatre 148 feet in diameter, still entire, with 5 rows of seats, and part of one of the great Roman ways, with the ruins of ancient buildings upon both sides. Coins, gems, and intaglios have been found in considerable numbers.—The population comprises Arabs, Jews, Moors, Turks,

Mamelukes, Christians, and negro slaves. The Arabs are of the same family as the Bedouins of Arabia, and their language does not differ materially from Arabic. They form the bulk of the population, and generally reside in the country districts. The towns are mostly peopled by Moors, Jews, and negro slaves, none of the other races being very numerous. Some of the Arabs have fixed homes and reside in villages, but many of them are nomadic.—There are some manufactures of woollen goods, and cloth for tents is made of goats' hair. The trade of Tripoli is very considerable. The exports by sea consist chiefly of wool, cattle, hides, gold dust, ostrich feathers, ivory, gum, dried fruits, saffron, senna, and different kinds of drugs, barilla, and sheep's fat; and the imports are clothes of every description, spices, sugar, coffee, spirits, arms, cutlery, hardware, &c. Caravans arrive from the interior of Africa twice a year, and bring slaves, gold dust, &c., which are exchanged for goods of European manufacture. The annual caravans from Morocco, on their way to and from Mecca, pass through the country, but their size has diminished greatly of late years.—Like the governments of the other Barbary states, that of Tripoli is a complete despotism. The bey is generally selected from among the Turkish officers resident at the capital, and confirmed by the sultan. In former times the revenue was chiefly derived from the prizes taken by corsairs, and the sale of the Europeans captured into slavery; but since these sources have been cut off, a system of monopolies exceedingly injurious to trade has been adopted. The bey of Fezzan and the sheiks of Barca and some neighboring tribes pay tribute, and a land tax is imposed, together with one on Jews and merchants, as well as on exports and imports. The religion is almost entirely Mohammedanism; but the temperance enjoined by the prophet is not practised in Tripoli. Wine shops are kept openly, and receive the sanction of the government by paying a heavy license fee. Education is not much attended to, and the people are exceedingly ignorant and bigoted.—After the destruction of Carthage, Tripoli, then called Africa Syrtica, became a Roman province, and the 8 cities of Sabrata or Abrotunum, Cea, and Leptis Magna, under the name of Tripolis, formed a kind of federal union. It was conquered by the Vandals in the 5th century, and by the Mohammedans under the caliph Omar and his successor. After the caliphate was dissolved Tripoli became an independent state. The capital was taken by the king of Sicily in 1146, and retaken by Yakoub and the fortifications destroyed in 1184. It was afterward subject to Tunis till about 1510, when it was conquered by the Spaniards; and it was ceded by the emperor Charles V. to the knights of St. John of Jerusalem after their expulsion from Rhodes in 1580. The only stronghold then consisted of a castle, against which Sultan Solymán sent an expedition in

1551, when the knights were expelled, and the tract of country which at present constitutes the pashalic was annexed to Tripoli. The famous corsair Dragut, who had assisted at its capture, was made the first governor, and he initiated a system of piracy which was continued for centuries. The Christian nations and their commerce were the objects of attack, and all prisoners taken were sold into slavery. The capital was bombarded by the French fleet in 1688, when the pasha professed submission to Louis XIV. Notwithstanding this, however, and a war with the United States growing out of the practice, the Tripolitans continued their depredations upon foreign shipping even down to the year 1816, when a British force visited Tripoli and compelled the bey to renounce piracy and agree to treat all future prisoners according to the usages common among civilized nations. Though Tripoli is nominally a dependency of the Ottoman empire, the allegiance is principally due to the fact of the sultan being the chief of the Mohammedan religion; and the bey enters into treaties with foreign powers without consulting any superior. At first the governors or beys were appointed from Constantinople, and supported by a Turkish garrison; but a Moorish chief who was second in command rebelled successfully in 1718 and was proclaimed bey by the people. The government became hereditary in his family, and continued so till 1882, when, in consequence of more than ordinary oppression and tyranny, the last bey of the line was obliged to abdicate, and the Porte has since resumed its nominal authority. The chiefs of the interior acknowledge but slight allegiance, and keep on friendly terms with the bey merely because the commerce carried on through the capital is advantageous to them. The Arabs sometimes resort to open hostilities, and so late as 1855 they defeated the bey troops, and advanced to the immediate vicinity of the capital.—TRIPOLI (anc. *Cea*), the capital, is situated on the Mediterranean, 600 m. S. E. from Algiers, and 300 m. S. from the coast of Sicily, in lat. 32° 54' N., long. 13° 11' E.; pop. about 20,000. It stands upon a rocky promontory with the sea on the N. and E. sides, and is joined to the mainland on the S. and W. by a sandy plain. Toward the land it is defended by a wall flanked by bastions, and to seaward there are strong batteries and a castle at the S. E. point, which is the residence of the bey. The streets are exceedingly narrow and uneven, and the houses are generally mean and huddled together without regularity. They are nearly all one story high, without windows toward the streets, built of stones and mud, and whitewashed. Tripoli contains many mosques, 6 of which are handsome buildings, ornamented with numerous minarets. The roof of the great mosque is formed by a number of small cupolas, supported by 16 marble columns, supposed to have been taken from a Christian church. It is richly ornamented in

the interior, and said to have a very imposing effect. There are 2 or 3 Christian churches, a Franciscan convent, and several synagogues; and all religions are tolerated within the limits of the city. The pasha's residence is an immense building of very irregular appearance, having been constructed at different times. There are numerous caravansaries for the accommodation of travellers and merchants; and many of the public baths are built of marble and ornamented with cupolas. There are two bazaars, one of which is occupied by small shops, and the other by slave dealers, who bring the slaves from the interior. Woollen goods (particularly carpets), leather, and potash are manufactured. A great part of the trade of the state, as well as that of the interior of Africa, is centred in Tripoli. The traders are principally Jews, who have monopolies farmed out to them by the government. The foreign trade by sea is carried on chiefly with Malta, Marseilles, Leghorn, Trieste, and several towns of the Levant; and by land by means of caravans with all the surrounding countries as far as Morocco, Timbuctoo, and Mecca. Tripoli contains several remains of antiquity, the most remarkable of which is a triumphal arch constructed of large blocks of marble, erected in A. D. 164 to the Roman emperors M. Aurelius Antoninus and Lucius Verus; the inscription is perfect, although the sculptures are greatly defaced. It is now used as a storehouse for goods.

TRIPOLI, or TARABLOOS (anc. *Tripolis*), a seaport town of Syria, on the shore of the Mediterranean, in lat. 34° 26' N., long. 35° 49' E., 48 m. N. by E. from Beyrout, and 94 m. N. W. from Damascus; pop. about 15,000, one half Greek Catholics. It stands at the foot of an off-set of Mt. Lebanon, on a small triangular plain, with the sea at a little distance on the N. and S. sides. A hill on the E. is crowned by an old castle; and the town is divided into two parts by the Nahr Kadesha, that to the N. being the port. The harbor is sheltered by a projecting point of land, but is small and shallow, and is not considered safe. There are several mosques, most of which were formerly Christian churches, and are generally fine buildings. Tripoli is one of the neatest towns in Syria, and is surrounded by many fine gardens and groves of orange and other fruit trees; but the ground in the neighborhood is marshy, and the climate is in consequence unhealthy at certain seasons. It is a place of considerable trade, the exports consisting chiefly of silk, wool, cotton, tobacco, wax, oil, cochineal, galls, soap, and especially sponges, the fishery of which occupies a large number of the inhabitants. The commerce is chiefly in the hands of Greeks. French steamers touch here 4 times a month. It is the see of a Greek bishop, and the residence of several consuls.—Tripolis was an important maritime town of Phœnicia, and derived its name from being the colony of the three cities of Tyre, Sidon, and Aradus, each holding a separate quarter of it. It was taken by the crusaders in 1109,

who burned a valuable library, and erected it into a county for Raymond of Toulouse.

TRIPOLI, an earthy substance, originally procured from Tripoli in Africa, used as a polishing material, of fine sharp grain, yellowish gray or whitish, burning white. It consists almost entirely of silica, and when examined by the microscope is found to be composed of the exuvise or skeletons of infusoria, the families of which are readily recognized. Specimens of it from Billen in Bohemia, Santaflora in Tuscany, the Isle of France, and Francisbad near Eger, have been examined by Ehrenberg. The substance has sometimes been confounded with the English rotten stone.

TRIPOLITZA, or TRIPOLIS, a town of Greece, in the Morea, capital of the nome of Arcadia, 22 m. S. W. from Argos; pop. 8,800. It is situated in a plain 3,000 feet above the sea, and owes its name, signifying triple city, to its being the modern representative of the cities of Mantinea, Tegea, and Pallantium, which occupied the same plain. Before the revolution it was the residence of a Turkish pasha and capital of the Morea, and had 20,000 inhabitants. The Greeks took it in 1821 and put the inhabitants to the sword, 8,000 male Turks having perished, beside women and children. In revenge for this outrage, Ibrahim Pasha, having occupied it in 1825, destroyed literally every house in the place. It has since been partially rebuilt. The ruins of Mantinea may be seen at Paleopoli, about 8 m. to the N., and of Tegea at Fiali, nearly the same distance S. (See MANTINEA, and TEGEA.) Pallantium probably occupied the site of Tripolitza itself.

TRIPTOLEMUS, in Greek mythology, a son of Oceanus and Terra, or, according to another tradition, of Celeus, king of Attica, and Neera, also called Metanira or Polymnia. He was born at Eleusis, and while still young he was cured of a dangerous illness by Ceres, who had been hospitably entertained by his father while engaged in the search for her daughter. To repay the kindness of Celeus, the goddess took especial care of Triptolemus, and put him on the fire in order to burn out whatever particles of mortality he had derived from his parents. But his mother, discovering her, prevented the accomplishment of her design. Ceres, unable to make him immortal, taught him agriculture, how to sow corn and to make bread, and also presented him with her dragon chariot, with which he rode over all the earth, distributing corn to all its inhabitants. Afterward he reigned at Eleusis. Triptolemus was the great hero of the Eleusinian mysteries.

TRISMEGISTUS. See HERMES TRISMEGISTUS.

TRISSINO, GIOVANNI GIORGIO, an Italian author, born in Vicenza in 1478, died in Rome in 1550. He studied the Greek language under Chalcondylas, and became also an elegant Latin and Italian writer. At a mature age he was employed by Popes Leo X. and Clement VII. upon several diplomatic missions. He wrote *Sofonisba*, the first Italian regular tragedy;

L'Italia liberata dai Goti, an epic in blank verse; and *La poetica*, a treatise on poetical art. To his suggestion is attributed the present method of writing the *v* and *j* of the Roman alphabet differently from the *u* and *i* with which they were before confounded. He also endeavored to introduce distinct signs for the different sounds of *o* and *e*.

TRISTAN DA CUNHA, the largest of a cluster of three islands in the S. Atlantic ocean, claimed by Great Britain, lying S. S. E. from St. Helena, in lat. 37° 6' S., long. 12° 2' W. The others are called Nightingale and Inaccessible islands, and can only be approached in a calm. Tristan da Cunha is about 20 m. in circumference, and rises abruptly from the water on 8 sides to a height of 8,326 feet. On the N. side an extensive plain stretches along the base of the mountain, which is an extinct volcano. Vessels touching can procure supplies. It was named after a Portuguese navigator who discovered it in 1506.

TRITON, in Greek and Roman mythology, a marine deity, the son of Neptune. He was represented as having the form of a man above and that of a fish below, and as bearing a conch-shell trumpet, the sound of which soothed the turbulence of the waters. Tritons are mentioned in the plural as identical with the fabulous mermen of the northern nations.

TRITON, the proper name of the tailed batrachians of the old genus *triton* (Laur.), generally called newts or water salamanders; they all belong to the northern hemisphere, and their species are most numerous in North America. The tail is depressed and adapted for swimming in most, though many are not strictly aquatic, but pass much of their life on the land, some visiting the water only during the breeding season; indeed, by reference to the article SALAMANDER it will be seen that the distinction into terrestrial and aquatic species is very indefinite, species with either of these habits being found in one genus. In the breeding season, in the spring, the males acquire a fin-like fringe along the back and tail and membranous appendages to the toes; the species are difficult to distinguish on account of the varieties of sex, age, and season. Reproduction takes place by means of eggs, which are fecundated before they are deposited, and the young resemble tadpoles in form and gills. The most carefully studied species is the great triton or water newt of Great Britain (*T. cristatus*, Flem.), about 6 inches long, of which the tail is about $\frac{2}{3}$; this species will suffice for the generic description. The body is naked, but covered with warty tubercles, and with glandular pores behind and over eyes and along sides; toes without nails, 4 anterior and 5 posterior; the dorsal and caudal crests separate; tongue slightly free on sides, and more free and pointed behind; palate with a double longitudinal series of teeth; no parotids nor glands along the back. The smooth-skinned species, without lateral pores and with a continuous

dorsal and caudal crest, have been noticed under ERR. The head is flattened, nose rounded, gape large, teeth numerous and small, and the neck hardly distinct from the head and body. It is common in ponds and ditches, and one of the most aquatic of the family, swimming by means of the tail, the legs being turned back against the body; the legs are used as balancers in the water, and for a slow and feeble creeping on land; the skin comes off in shreds in the water, and is swallowed. It is said not to be able to breed until the 8d year, and to pass the entire period between the end of the tadpole state and the breeding season on the land, the young in winter hiding in solitary holes in the ground, and the adults hibernating in company rolled together in a ball a few inches in diameter. The eggs are deposited on the leaves of aquatic plants which are folded around them, one egg to each leaf; the anterior lobes of the branchiae are modified into prehensile organs by which the tadpole fixes itself to bodies under water, being absorbed when the anterior feet are sufficiently developed; the young, which are born in June or July, remain, according to Bell, without much change till the following spring, when they acquire legs and leave the water, their parents in a few weeks resuming a terrestrial existence. In the water they are voracious, feeding on aquatic animals, insects and larvæ, the tadpoles of the frog, and even those of their own species. They are noted for their tenacity of life under mutilation and exposure to severe cold, and for their power of reproducing lost parts; yet with all this tenacity of life, it is remarkable, says Prince Musignano, that they should die in violent convulsions on having a little salt sprinkled upon the body. It is blackish or light brown above with darker round spots and bright reddish orange below with round black spots, and the sides dotted with white.—The common many-spotted triton of the Atlantic states (*T. dorsalis*, Harlan; genus *notophthalmus*, Raf.) is about 4 inches long, of which the tail is one half; it is olive or greenish brown above, with a row of circular vermilion spots on each side, and below orange studded with small black dots; eyes prominent, with flame-colored iris; posterior limbs twice as large as anterior; it is eminently aquatic, and dies soon out of water from the drying of the skin; it is torpid only in the severest weather; it is found from Maine to Georgia, forming a very lively and interesting animal for the fresh water aquarium, and easily obtained. The tiger triton (*T. tigrinus*, Holbr.; genus *ambystoma*, Tschudi) is $6\frac{1}{2}$ inches long, bluish black above and on limbs, with irregular markings of lemon color, and below ashy with dusky yellow blotches; it is found in the New England and middle states. The black triton (*T. niger*, Holbr.; genus *desmognathus*, Baird) is $4\frac{1}{2}$ inches long, black above, with a tinge of blue, and purplish below; it is found from Massachusetts to Florida and Louisiana, and is said

to be entirely aquatic. The great triton (*T. ingens*, Holbr.; genus *ambystoma*, Tsch.) is 10 to 13 inches long, bluish slate above, with irregular pale ash blotches, throat dark brown, and abdomen slate-colored; this is the largest species, eminently aquatic, and found in the western states.—The name of TRITON is also given to a genus of gasteropod mollusks of the murex family, having a conical and elongated shell, spirally convoluted. The *T. variegatum* (Lam.), 12 to 16 inches long, from the Indian seas, is the well known sea conch or trumpet of the god Triton; this species, as well as the *T. australe* (Lam.), is used by the Polynesians as a horn; by blowing in the shell through a hole in the apex, a loud and mellow sound is produced.

TRIUMPH (Lat. *triumphus*), generally, a solemn procession for the purpose of celebrating a victory. Although honors of this kind have been bestowed from time immemorial by warlike races upon victorious generals, they became nowhere else so closely identified with national habits and institutions as among the ancient Romans, who encouraged the observance of them as a stimulus to martial exploits. Hence a triumph may be defined as the highest military honor that could be obtained by a Roman general, who entered the city in a chariot drawn by 4 horses, preceded by his captives and spoils and followed by his army, with which escort he passed along the Via Sacra, and ascending to the capitol sacrificed a bull to Jupiter. A triumph was granted by the senate to a general who had gained important successes by land or sea, if he had already held one of the great offices of state; if the victory had been gained under his auspices and with his troops; if the advantage had been positive and the number of enemies slain in a single battle at least 5,000, and if it had been gained over a foreign enemy and not in a civil war; if the national dominion had been extended, and not merely recovered or relieved from the presence of the enemy; and if the war had been actually concluded so as to permit of the army's being withdrawn from the conquered country. Occasional deviations from these conditions are recorded, but they were in the main strictly observed. The general claiming the triumph having sent to the senate an account of his exploits, that body, if the intelligence proved satisfactory, generally decreed a public thanksgiving, called a *supplicatio*; and at the conclusion of the war he met them without the city walls to urge his pretensions in person. The right of the senate to bestow triumphs, however, was not an exclusive prerogative, instances being on record in which the comitia of the tribes assumed it, and even where generals triumphed in defiance of the senate and the people. But a disappointed general commonly contented himself with going through the forms of a triumph on the Alban mount. The consent of the senate having been obtained, and a sum of money voted to defray the necessary expenses, the

successful general was invested with the *imperium* within the city for the day of triumph, until which occasion he remained outside of the walls. The procession, at first simple and impressive, was in later times transformed into a pageant of extraordinary splendor, and minute regulations prescribed the arrangement of its various parts. The populace in holiday attire were present along the whole route, altars and temples were adorned with garlands, and a general festival prevailed. The general himself, attired in a gold-embroidered robe and flowered tunic, and bearing in one hand a laurel bough and in the other a sceptre, stood upright in a circular chariot drawn by 4 horses, in which was also stationed a slave, who, according to some authorities, reminded him amid the acclamations of the multitude that he was but mortal. The inhuman practice also prevailed of putting to death several of the captive leaders while the procession was ascending the Capitoline hill. After the sacrifice was performed at the temple of Jupiter Capitolinus, the general deposited his laurel wreath in the lap of the god, and the ceremonies of the day ended with a public banquet. Naval triumphs were similar in character, but fewer in number, and generally on a smaller scale. After the overthrow of the republic, the emperors, in virtue of their authority as commanders-in-chief of the armies of the state, claimed the exclusive right of celebrating triumphs; and until A. D. 584, when Belisarius entered Constantinople in triumph after the overthrow of the Vandal kingdom in Africa, no subject had for more than 5 centuries enjoyed that distinction. This was the 850th triumph in Roman history, and the last ever celebrated. A lesser kind of triumph, called an ovation (*ovatio*) from the practice of sacrificing a sheep (*ovis*) instead of a bull, was granted to a general whose success had been considerable, though not of a character to entitle him to a triumph. In such cases the victor entered the city on foot, attended by a less imposing retinue, a conspicuous feature of which was a numerous band of flute players.

TRIUMPHAL AROH. See AROH.

TRIUMPHAL COLUMN. See COLUMN.

TRIUMVIRATE, an office filled coördinately by 3 persons. Several magistracies of this description were recognized in the Roman government, of which the most important was that for the regulation of public affairs—*triumviri reipublica constituenda*. Though magistrates with this title are thought to have been appointed as early as 360 B. C., there is no certain mention of them till toward the close of the republic, when the supreme power was shared between Octavius, Antony, and Lepidus, as triumvirs. They received the office for 5 years in 48 B. C., and upon the expiration of that term for 5 years more. The coalition between Julius Cæsar, Pompey, and Crassus, in 60 B. C., is often called a triumvirate, but improperly, as they were never invested with any office under that title. Administration by tri-

umvirs was apparently much favored by Roman legislators. A triumvirate was instituted in 292 B. C. of officers to inquire into all capital crimes (*triumviri capitales*); another superintended the formation of every colony (*triumviri colonia deducenda*); another was charged with the prevention of fires, and went the rounds of the city every night for that purpose (*triumviri nocturni*); and there were many other triumvirates of minor importance, either permanent or temporary.

TROCHEE (Gr. *τρεχων*, to run), in poetry, a foot consisting of a long and a short syllable. It is also called choreus, and is especially used in verse requiring rapid movement, from which circumstance it derives its name. Trochaic verse is generally employed in lines of 2, 4, and 6 feet, and the trochee (- -) interchanges easily with the dactyl (- - -), tribrach (- - -), anapaest (- - -), and spondee (- -). In addition to the trochaic verse of 2, 4, and 6 feet, known to the ancients and the moderns, the latter have also employed the trochaic verse of 5 and of 7 feet, although the tetrameter is the one principally in use.

TROEZEN, an ancient city of Greece, situated in a fertile plain in a territory of the same name, forming the S. E. corner of Argolis. It was founded probably by the Ionians, and according to Homer was subject at the time of the Trojan war to Argos, from which it afterward received a Doric colony. Subsequently it became a prominent maritime city, founded Halicarnassus and Myndus in Caria, and probably Pæstum in Magna Græcia, and was conspicuous in the wars with Persia, its harbor being the rendezvous of the Grecian fleet after the sea fight at Artemisium. During the Peloponnesian, Corinthian, and other wars, it adhered to the side of Sparta. After the establishment of the Macedonian rule over Greece it was in the hands of various contending parties, and continued a place of some importance until the time of Pausanias, who describes its public buildings in detail; but after this period we have no account of its history. The ruins of the ancient city lie near the village of Damala, and consist principally of Hellenic foundations with Frankish or Byzantine superstructures. In 1827 the Greek national assembly was held here, at which Capo d'Istria was chosen president for 7 years. Trœzen is celebrated as the birthplace of the Attic hero Theseus.

TROGLODYTES (Gr. *τρογλοδυτης*, from *τρογλη*, a cave, and *δυω*, to enter), the name given by the ancients to tribes of men who resided in caves. Several such are mentioned by ancient writers as inhabiting parts of Ethiopia, upper Egypt, the borders of the Red sea, Moesia, Mauritania, and the northern part of the Caucasus. At the present time, in part of Arabia, the mountainous region encompassing the wadys are filled with caves, which have been converted into permanent habitations by half savage tribes of Bedouins, and it is probable that these belong to the same race as the troglodytic

population of Ptolemy and other Greek geographers. In the early history of the Christian church the name was also applied to certain heretics, who, rejected by all parties, held their meetings in caves.—In natural history, Linnæus placed the African orang-outang under the genus *homo* with the specific name of *troglodytes*, next to *homo sapiens*; and this is the *troglodytes niger* of Geoffroy and the *simia troglodytes* of Blumenbach. The term is now applied to a genus which includes the chimpanzee and the gorilla, and also to a genus of the *troglodytina* or wren family of birds.

TROGON, and *Corcorac*, names given to the fissirostral birds of the family *trogonide*, the second name being derived from their peculiar melancholy cry. The bill is short, strong, curved, broader than high, triangular seen from above, with the margins and tip usually serrated, the base provided with tufts of bristles, and the gape wide; wings moderate and rounded; tarsi short and weak, more or less feathered; toes of unequal length, and arranged in 2 pairs, the inner being turned backward. There are about 40 species in the tropical regions of both hemispheres, but especially numerous in South America; they frequent thick and damp forests, feeding on insects, which they seize on the wing or pick from the bark of trees, and on fruits and berries; they are most active in morning and evening. A few live in the islands of the Indian archipelago, belonging to the genus *harporhynchus* (Swains.), having the edges of the bill smooth; and one genus (*apaloderma*, Swains.) in Africa, with only the lower mandible serrated; the American may be distinguished from the old world species by their barred tail. Though the neck and feet seem too short for the bulky body, the plumage is usually beautiful, often with metallic brilliancy, the splendor of their appearance being increased by the elegant and long tail. The eggs, 2 to 4, are laid in the holes of rotten trees, and several broods are raised in a year. The species vary in size from a thrush to a magpie; it is rare to obtain good specimens, as they frequent the highest trees of the thickest forests, and when shot lose many of the soft and delicate feathers by the fall to the ground; the skin is very tender, and renders the operation of skinning so difficult that the natives dry the body with the feathers on.—In the genus *trogon* (Möhr.) the 1st quill is short and the 4th the longest. The red-bellied trogon (*T. curvirostris*, Linn.) is about a foot long, green above, red below, with the throat black, and the coverts and tail striped with the same; it is a native of Mexico. The peacock or splendid trogon (*calisirus resplendens*, Swains.) has the edges of the bill smooth, the wing coverts long and curved, and the upper tail coverts greatly prolonged, entirely concealing the tail; it is larger than the last named, and the middle tail coverts are 3 to 3½ feet in length; it is of a beautiful bronzed and golden green above and on the throat, and scarlet below; it is found in Mexico and Cen-

tral America, and was celebrated in the mythology of the ancient Mexicans; the gorgeous feathers of this and the preceding species are much prized by the natives for ornaments, and for use in their festivals, wars, and religious ceremonies; a crest of silky green feathers adds to the graceful appearance of the bird; it is the *T. pavoninus* (Temm.). There are many other species in Mexico and South America, generally green above and red or yellow below; the females are brownish where the males are green. The Asiatic species resemble the American ones in colors and habits.—For descriptions and figures of this brilliant family, see the "Monograph of the Trogonidae," by John Gould (fol., London, 1838).

TROLLOPE, FRANCES (MILTON), an English novelist, born in Heckfield, Hampshire, about 1780. She was the daughter of the Rev. William Milton, was well educated, and in 1809 was married to Anthony Trollope, barrister at law and a member of a distinguished family of Lincolnshire, who died at Bruges in 1835. A large portion of her married life was spent at Farrow, but in 1829 she visited the United States, where she remained 8 years. On her return she gave an account of her impressions in a work entitled "Domestic Manners of the Americans" (2 vols. 8vo. London, 1832), in which the indelicate and ridiculous phases of American character and habits were depicted in a manner which showed the writer's intimate acquaintance with the coarseness she described. The work was very successful in England, and created much bitter feeling at the time in the United States. She afterward produced in rapid succession so large a number of novels and accounts of travels, as to render her the most voluminous English authoress of the times. Her first work on America was followed by a novel entitled "The Refugee in America" (1832), and in 1836 by "The Adventures of Jonathan Jefferson Whitlaw." About 1844 she went to Florence, where she has since resided. Among her books of travels are: "Belgium and Western Germany in 1833" (2 vols., 1834); "Paris and the Parisians in 1835" (3 vols., 1836); "Vienna and the Austrians" (2 vols., 1838); "A Visit to Italy" (2 vols., 1842); and "Travels and Travellers" (2 vols., 1846). In the province of romance some of her best works are: "The Vicar of Wrexhill" (3 vols., 1837); "The Romance of Vienna" (1838); "The Widow Barnaby" (3 vols., 1839); "Life and Adventures of Michael Armstrong, a Factory Boy" (3 vols., 1840); "The Widow Marston," a sequel to "The Widow Barnaby" (3 vols., 1840); "One Fault" (3 vols., 1840); and "Charles Ochesterfield, or the Adventures of a Youth of Genius" (3 vols., 1841). Her later writings are much inferior to her earlier ones, and her works throughout are distinguished by an observation, coarse satire, and amusing details. Her literary activity continued unabated until 1856.—**THOMAS ADOLPHUS**, an English author, son of the preceding (born in 1810), has

published "The Girlhood of Catharine de' Medici," a biographical work under the title of "A Decade of Italian Women," "Paul the Pope and Paul the Friar" (1861), and other works, including several volumes of travels. His brother **ANTHONY** is a successful novelist. Occupying in Ireland the situation of a surveyor of the general post office, he began his literary career by two novels on Irish subjects, "The Macdermots of Ballycloran" (1847), and "The Kellys and the O'Kellys" (1848). These were followed by "La Vendée" (1850), a historical romance, "The Warden" (1858), "The Three Clerks," "Barchester Towers," "Doctor Thorne" (1858), "The Bertrams" (1859), "Castle Richmond" (1860), "Framley Parsonage" (1861), and "Orley Farm," a serial novel begun in 1861. He writes largely both for English and American periodicals. He has also published "The West Indies and the Spanish Main." He has repeatedly visited the United States, his last journey in that country having taken place in 1861-2.

TROMBONE, a brass wind instrument, supposed to be identical with the sackbut, and which constitutes one form of the trumpet. By means of sliding tubes great depth and power of tone are produced, and the instrument when judiciously employed, as in the last act of Mozart's *Don Giovanni*, is capable of splendid effects. It is however too frequently a noisy and unwelcome element in the orchestra, and is used to better purpose in military bands. Trombones are of 3 kinds, alto, tenor, and base; the first having a compass from C, the 2d space in the base, to G, an octave above the treble clef; the 2d from B, the 2d line in the base, to A, the 2d space in the treble; and the 3d from C, an octave below the 2d space in the base, to G, the 2d line in the treble.

TROMP, MARTEN HARPERZDOON VAN, a Dutch admiral, born at Briel in 1597, killed July 29, 1653. He was the son of a naval officer, and when 8 years old was taken to sea by his father, who was killed in an engagement off the coast of Guinea with an English vessel. Young Van Tromp was taken prisoner, and from this time the events of his life are very uncertain until 1622, when he was a lieutenant on board a ship of the line. Two years afterward he commanded a frigate under Prince Maurice, and later served under Peit Hein, who fell dead by his side in an engagement with the Spaniards in August, 1629. About this time Van Tromp resigned his position, but in 1637 he was created by the stadtholder lieutenant-admiral, and placed in command of 11 vessels, with which he did so much damage to the Spanish shipping that he was presented with a gold chain by the states, and decorated with the insignia of the order of St. Michael by the French king. Created admiral of Holland in 1639, he attacked the Spanish fleet near Gravelines, and destroyed 5 ships of the line and 4 frigates; and in October of the same year he gained such a victory over the Spanish fleet

under Oquendo, between Dunkirk and Nieuwport, that his name became famous throughout Europe. War breaking out between Holland and England in 1652, Van Tromp fought several great battles in that and the succeeding year (see BLAKE, ROBERT); and in July, 1658, he engaged the English fleet under Monk, near the coast of Holland, and during the conflict was shot through the head by a musket ball. "Courage, my boys," he exclaimed as he fell; "my course is ended with glory." Van Tromp was the most celebrated of the Dutch naval officers, and is said to have been successful in 38 engagements. He was buried with great splendor in the church at Delft.—CORNELIS VAN, a Dutch admiral, second son of the preceding, born in Rotterdam, Sept. 9, 1629, died in Amsterdam, May 29, 1691. Educated for his hereditary profession, he was appointed in his 19th year to the command of a ship destined to act against the African pirates, and two years later was created vice-admiral. From this time he was constantly engaged in naval enterprises until 1656, when he retired to private life, but resumed active employment in 1662. When war broke out between England and Holland in 1665, he was attached to the squadron commanded by Admiral Opdam, and was present at the battle of Solebay. Here, although the Dutch fleet was defeated, Van Tromp gained great reputation by the skilful manner in which he conducted the retreat. When a new squadron was fitted out, he was appointed to the chief command, although belonging to the party of the prince of Orange; but on the return of De Ruyter, he was superseded by that commander, under whom he refused to serve. In 1666 he was present at the naval battle in the Downs between De Ruyter and Monk, which lasted 4 days and ended in a victory for the former. In August of the same year he participated in another battle, and was successful in defeating the portion of the English fleet opposed to him, but, following his victory too far, was unable to render any assistance to De Ruyter, who was worsted. The latter commander complained of his conduct, and the states, on the advice of De Witt, deprived him of his command, and forbade his holding any communication with the fleet. In 1673, while war was again raging between Holland and the united powers of France and England, his commission was restored him by the prince of Orange, and a reconciliation took place between him and De Ruyter. In this war he distinguished himself highly. In 1675 he visited England, where he was received with great honor, and created a baronet by Charles II. In 1676 he was sent at the head of a fleet to assist Denmark, then carrying on a war with Sweden, and for his services was invested by the king of the former country with the order of the elephant, and raised to the dignity of count. On his return to Holland he succeeded De Ruyter as admiral lieutenant-general of the United Provinces. In

1691 he was appointed commander of the fleet destined to act against the French, but died before it was fully equipped and ready for sea.

TRONDHJEM. See DRONTHIM.

TROOPIAL (Fr. *troupiale*), a name given to several species of the *icterina* and *agelaius*, sub-families of American conirostral birds, in some respects resembling the starlings of the old world, and in others coming near the finches; they have the 9 primaries of the finches, but the bill is larger, straight, the base without bristles and the tip without a notch. The name is derived from their habit of associating in large troops. In the *icterina* the bill is generally longer than the head, straight and sharp-pointed; wings long and pointed, and tail usually wedge-shaped; toes moderate and formed for perching. The prevailing colors are yellow or orange and black; they are generally called orioles in North America, and a well known species has been described under BALTIMORE BIRD; hang-nest is another appropriate name, derived from their habit of suspending the nest from the extremity of slender branches.—The common troopial (*icterus vulgaris*, Daud.) is about 10 inches long, with a straight bill; back and abdomen yellow; head, neck all round, breast, and tail black; a white band on the wings; feathers of throat elongated and pointed; it is a native of northern South America and the West Indies, sometimes coming to the southern United States. They move in flocks, sometimes mingled with other species, and show a great partiality to the neighborhood of man, in whose cultivated fields they find a rich supply of insect food; they are excellent fliers, and equally at home on the ground or in trees; they are loquacious at all seasons of the year; their flesh is excellent. There are several other species in Mexico, Texas, and Central America. The orchard troopial (*I. spurius*, Bonap.) very much resembles the Baltimore oriole in the pattern of its colors, the orange red of the latter being replaced by dark chestnut, the tail entirely black and more graduated, and the bill slenderer and more curved. It frequents orchards, where it does good service in destroying insects in the blossoms; it is found throughout the United States from the Atlantic to the high central plains; the nest is hemispherical, 3 or 4 inches deep, made of long grasses very neatly interwoven, and suspended to drooping twigs frequently of the weeping willow. It is often kept in a cage for its lively movements and pleasing song.—The only other genus of the *icterina* which can be mentioned here is *camisus* (Cuv.), so called from *casius* (a helmet), the bill rising on the forehead in a crescent shape: nostrils basal, naked, pierced in the substance of the bill; 3d and 4th quills longest, and tail long and graduated; tarsi and toes strongly scaled. There are about 20 species, peculiar to tropical America, living in the forests and also near human habitations, in vast troops; they eat fruits, berries, insects, and larvæ.

The nest is most ingeniously woven by both sexes, made of fibres and dried grasses, of a cylindrical or gourd-like form, and sometimes 8 feet in length; the lower part is hemispherical, the opening near the top, and the fabric suspended from the ends of slender twigs of high trees, out of the reach of monkeys and snakes; many nests are made on one tree, and sometimes those of different species together. They are docile in captivity, and learn to whistle and to articulate words; they are generally black, contrasted with bright yellow, especially toward the tail. The *C. cristatus* (Daud.), of Surinam, is about as large as a magpie; the *C. hemorrhous* (Daud.) has a deep red rump and back.—In the sub-family *agelaius* the bill is stout, short, conical, nearly straight, and sharp-pointed; tarsi as long as the middle toe; toes long and slender, and claws long and curved. Some of the birds of this sub-family have been described under BLACKBIRD, and BOBOLINK, specimens respectively of the genera *agelaius* (Vieill.) and *dolichonyx* (Swains.). *Leistes* (Vigors) resembles *agelaius*, but has a shorter tail; the species live generally in flocks in marshy places and on the borders of the great rivers of South America, on the ground or in low trees; the nest is suspended among the reeds near the ground, and is made of stalks of grass; the eggs are 8 or 4. In the genus *molothrus* (Swains.) the bill is short and stout, elevated at the base, and advancing on the forehead; wings long and pointed, 1st and 2d quills the longest; tail moderate and nearly even. Of the few species, only one is found in the United States, the cow blackbird, or cow-pen bird (*M. pecorarius*, Swains.); it is about 8 inches long and 19 in alar extent; in the male the prevailing color is shining black, with a purplish and steel-blue gloss; the head, neck, and anterior part of breast, light chocolate brown; the female is light olivaceous brown; bill and feet black. It is found throughout the United States from the Atlantic to California, though probably not on the Pacific coast; it frequents fields and farmyards, following cattle, sometimes picking ticks from their backs, and at others feeding on the seeds, worms, and insects contained in their dung; large flocks migrate to the north to breed in spring, returning in autumn. The females have the habit of dropping their eggs, singly, into the nests of other smaller birds, as sparrows, warblers, and flycatchers; in New England the summer yellow bird's nest is most frequently selected; the eggs thus stealthily dropped are of about the same size as the true ones, and are more quickly hatched by the foster parents; of course, with this habit the cow birds do not pair, nor display the lasting attachment of ordinary birds. The European cuckoo has the same habit of abandoning her progeny to the care of strangers; but this is the more remarkable in the present bird, belonging to a family proverbial for the ingenuity with which their nests are constructed. If the cow bird's egg be deposited in a newly finished

but empty nest, the makers generally abandon it; if in a nest already containing eggs, it is usually allowed to remain, though the makers are probably aware of the intrusion; the yellow bird has a way of disposing of the strange egg, which will be noticed under that title. The egg is pale grayish blue, with umber-brown dots and streaks, and the young is hatched in about a fortnight, the other eggs remaining unhatched; the intruder is fed by the foster parents, to the neglect of their own eggs, which, when the contained embryo has perished, are cast from the nest, and it is cared for long after it has left the nest. This species has no song, but a low muttering chuckle; the flesh is esteemed as food, and many are shot in the southern states; they roost among the reeds in swampy places, and come to feed in immense flocks, often in company with the red-winged blackbird and other troopials.

TROOST, GERAED, an American chemist and geologist, born in Bois-le-Duc, Holland, March 15, 1776, died in Nashville, Tenn., Aug. 14, 1850. He was educated at the university of Leyden, and, evincing a great proficiency in several branches of natural science, was in 1809 sent by Louis Bonaparte, king of Holland, on a tour of scientific observation in Java. The capture of the vessel in which he sailed by a privateer having interrupted this undertaking, he repaired in 1810 to the United States, where he passed the remainder of his life. Establishing himself in Philadelphia, he became a member of the academy of natural history, of which he was elected the first president, holding office until 1817. In 1814 he established the first alum works in the United States; and in 1825, having previously held for a short time the professorship of chemistry in the college of pharmacy in Philadelphia, he joined Robert Owen's community at New Harmony, from which he retired at the end of two years. Removing to Nashville in 1828, he was appointed professor of chemistry, mineralogy, and geology in the university of that city, and in 1831 geologist to the state of Tennessee, both of which positions he held until the close of his life. His reports on the geology of Tennessee, and numerous memoirs on geology and mineralogy published in the "Transactions" of scientific bodies in Europe and America, are his chief literary productions. His collections illustrating these subjects are said to have been the finest ever possessed by a single individual in the United States.

TROPE (Gr. τροπή, to turn), in rhetoric, an expression used in a different sense, or, literally speaking, turned from its primary signification, for the purpose of presenting an idea in a lively or forcible manner. The term is generally considered to comprise the figures called metaphor, allegory, metonymy, synecdoche, and perhaps a few others. Many words or phrases originally employed as tropes have by constant use acquired a derivative signification which has superseded the original one.

TROPHONTIUS, a Greek of the fabulous period, a son of Erginus, king of Orchomenus, or according to one legend, of Apollo. He built, with his brother Agamedes, the temple of Delphi, and the treasury of King Hyrieus in Boeotia. After his death he was worshipped as a hero, and had a celebrated oracle near Lebadea in Boeotia.

TROPHY (Gr. *τροφαιον*, from *τρεπω*, to turn, to defeat), literally, a memorial of victory erected on a field of battle. It consisted generally of the arms of slain enemies placed upon the trunk of a tree, and in later times upon a stone or metal pillar, with an explanatory inscription, and was consecrated to Jupiter or some other deity, whence it was regarded as inviolable. To the end also that hostile feelings might not be perpetuated, trophies were allowed to perish by natural causes, and any attempt to repair them when decayed was deemed sacrilegious. The practice of erecting them was common among the Greeks, and subsequent to 121 B. C. was adopted by the Romans, some of whose generals expended large sums in memorial works of this kind. These, however, were more frequently raised in Rome than on the field of battle, and in later times took the form of magnificent triumphal arches or columns.

TROPIC BIRD (*phaeton*, Linn.), a genus of web-footed oceanic birds, constituting the family *phaetonidae*. They are characterized by a long, strong, pointed bill, broad at the base, slightly curved, without nail and the edges finely serrated; nostrils at base of bill, lateral, and pervious; face covered with feathers; wings long and pointed, the first primary the longest; tarsi short and strong, feet small, and toes fully webbed; hind toe small; tail with 2 long, straw-like feathers, whence the French name *paille en queue* or straw-tail; sailors call them boatswain bird and marline-spike. In habits and appearance they come near the gulls and terns; they are chiefly confined to the tropics, so that the mariner knows, when they hover around his vessel, that he is in or near the tropical zone. Their powers of flight are great, and they are usually seen at considerable distances from land; they live almost entirely on the wing, and, when they do not return to the distant shore to roost, rest upon the surface of the ocean; they are excellent swimmers. The food consists of fish and other marine animals, which they dart upon from a great height; they are fond of following the shoals of flying fish, seizing them as they emerge from the sea to avoid the porpoises, tunnies, and other carnivorous enemies. They are not larger in the body than a pigeon, though longer; they congregate in considerable numbers at their breeding places, on rocky shores and desert islands, placing the nest on the ground or in holes in trees; the eggs are 2; their flesh is fishy and tough. The common tropic bird (*P. candidus*, Gray) is about 80 inches long and 88 in alar extent; it is a satiny white, the wings banded with black, and the head, back; and wings

tinged with cream color or light pink; first 5 primaries black on the outer webs, and the shafts of the long tail feathers black to near the end, where they are white; a black mark over eyes to occiput; bill orange red and iris brown; tarsus and toes yellow at base, webs and claws black. It sometimes comes near the Florida coast, but is usually seen in the tropical Atlantic far from land. The long tail feathers of the *P. phaniscus* (Gmel.), inhabiting the tropical Pacific, are of a bright red color, and are used as ornaments by the South sea islanders.

TROPICS (Gr. *τροπη*, a turn), in astronomy, two circles parallel to the equator, at such distance from it as is equal to the greatest recession of the sun from it toward the poles, or to the sun's greatest declination. That in the northern hemisphere is called the tropic of Cancer, and that in the southern the tropic of Capricorn, from their touching the ecliptic in the first points of those signs. (See *CANCER*, and *CAPRICORN*.) It is between the tropics that the sun's path is circumscribed, its annual movement being from one to the other and back again in the ecliptic.—In geography, the tropics, also known as that of Cancer and that of Capricorn, are the two parallels of latitude over which the sun is vertical at the solstices. (See *SOLSTICE*.)

TROPLONG, RAYMOND THEODORE, a French jurist and magistrate, born at St. Gaudens, department of Haute-Garonne, Oct. 8, 1795. He entered the legal profession in 1815, and, after distinguishing himself as king's attorney at various places, was in 1833 appointed president in the royal court at Nancy. He now commenced publishing the work that entitles him to the highest rank among the French jurists, *Le droit civil expliqué* (28 vols. 8vo., 1833-'58). In 1840 he was elected a member of the academy of moral and political sciences, and in 1846 was made a peer by Louis Philippe. On the revolution of February he joined the Bonapartists, and, on Dec. 22, 1848, was appointed first president of the court of Paris. In the same year he published a tract, *De la propriété*, which was extensively circulated. An original member of the new senate, Jan. 26, 1852, he was appointed one of its vice-presidents, and in 1854 its president, becoming meanwhile president of the court of cassation and grand cross of the legion of honor; and in 1858 he was named a member of the privy council of the emperor. Beside the works above mentioned, he has written *De l'influence du christianisme sur le droit civil des Romains* (1843; 2d ed., 1855), and *Du pouvoir de l'état sur l'enseignement* (8vo., 1844). He is also a contributor to the *Gazette des tribunaux*, the *Revue de législation*, and the *Moniteur*.

TROPPAU, a fortified town and the capital of Austrian Silesia, and of the circle and principality of Troppau, on the Oppa, a tributary of the Oder, 36 m. N. E. from Olmütz; pop. in 1857, 13,861. The city is well built, and has a

castle of the princes of Lichtenstein, a gymnasium, a school for the sons of soldiers, a library, a cabinet of natural history, and a museum of national antiquities. Woollen, linen, soap, paper, and leather are manufactured. The diplomatic congress, afterward removed to Laybach, was held here in the autumn of 1820.

TROUBADOURS. See **PROVENÇAL POETRY.**

TROUGHTON, EDWARD, an English astronomical instrument maker, born in Oct. 1758, died in London, June 12, 1835. He entered the firm of his uncle and brother, who carried on business as mathematical instrument makers, and became highly distinguished for his success in the construction of astronomical instruments; and it was said of him that "he improved and extended every instrument that he touched, and that every astronomical instrument was in turn the subject of his attention." He wrote articles in the "Philosophical Transactions," and in the "Edinburgh Encyclopedia."

TROUP, a W. co. of Georgia, bordering on Alabama, and intersected by the Chattahoochee river; area, about 370 sq. m.; pop. in 1860, 16,879, of whom 10,002 were slaves. The surface is hilly and the soil generally fertile. The productions in 1850 were 14,481 bales of cotton, 687,205 bushels of Indian corn, 120,802 of oats, and 142,884 of sweet potatoes. There were 3 tanneries, a woollen factory, 82 churches, and 1,440 pupils attending public schools. It is intersected by the Atlanta and West Point railroad. Capital, La Grange.

TROUP, GEORGE M., an American statesman, born on the Tombigbee river, then in the territory of Georgia, in 1780, died in Laurens co., Ga., May 3, 1856. He was graduated at Princeton college in 1797, was admitted soon after to the bar, and upon reaching the age of 31 was elected a member of the state legislature. Between 1807 and 1815 he was a representative in congress from Georgia, and in 1816 was elected a U. S. senator. From 1823 to 1827 he was governor of the state, and in 1829 was a second time elected to the U. S. senate, from which he retired before the expiration of his term on account of ill health. He was a man of great integrity, an impassioned speaker, and one of the most earnest and able of the advocates of state rights and state sovereignty.

TROUT, a name popularly restricted to the species of the salmon family inhabiting exclusively or principally fresh water, and embracing members of the three sub-genera of the old genus *salmo* made by Valenciennes, viz., *salmo*, *trio*, and *salar*; the family characters have been given under **SALMON.** The salmon trouts long to the genus *fario* (Val.), having one row of teeth on the vomer, the true salmon giving the palate smooth; the species are so called from the redness of the flesh, but all the trouts have this color at some epoch of their lives, depending probably on their food. The salmon trout of Europe (*F. argentatus*, L.; *salmo trutta*, Linn.), called also white

or sea trout, is found in the great lakes and rivers of that continent, many of which communicate with the sea; it varies considerably in color, like all of the family, according to the character of the water and the quality of the food; it is greenish gray or bluish black above, lighter on the sides, and silvery white below, with a few black spots above the lateral line; it attains a length of 2 to 2½ feet, and, being abundant in the markets of London and Paris, is next in value to the salmon, which it resembles in habits. Another very large and excellent species is the *F. Lemanus* (Val.), attaining a weight of over 80 lbs.; they are kept in private running waters, but require a large supply of small fishes for food; they ascend the streams from the lake of Geneva as the salmon does from the sea; they are easily and successfully transported to stock other lakes. The so called sea trout of the gulf of St. Lawrence (*salmo immaculatus*, H. R. Storer) has the flesh of a fine pink color and superior flavor; the color is sea-green above, lower parts and the fins white; it rarely exceeds a weight of 7 lbs.; it probably belongs to the genus *fario*. This species, often called salmon trout, affords in spring and summer excellent sport with a brilliant scarlet and gold fly, either from a stationary point, or from a boat under easy sail, with about 80 yards of line out and at least 70 more on the reel. There are several other species called salmon trout in lakes shut off from the sea and near the mouths of the rivers of Maine. The red-bellied trout (*F. erythrogaster*, Val.), of the lakes of New York and Pennsylvania, attains a length of 2 to 2½ feet; it is deep greenish on the back, lighter on the sides and below, the sides with red spots, and the abdomen orange red. The spots of trout resist the action of heat and even of alcohol for a long time.—The common brook or speckled trout of North America (*salmo fontinalis*, Mitch.) is from 8 to 20 inches long, pale brownish above with darker reticulated markings; sides lighter, with numerous circular yellow spots, many with a bright red spot in the centre; white or yellowish white below; the first ray of pectorals, ventrals, and anal edged with white and black, with the rest of these fins reddish. It is found abundantly in the streams of the British provinces, the New England, middle, and western states, and is everywhere highly esteemed as food; it is rarely taken weighing more than 1½ lbs.; the markings vary considerably according to locality and season; in New Brunswick and Nova Scotia it descends to the sea when it can; it is the same species from Labrador to Pennsylvania and Ohio. It is a great favorite with anglers, and its capture leads the lover of nature amid the most romantic scenery and at the finest season of the year; it is taken by the hook and line baited with a minnow, shrimp, worm, or artificial fly; in narrow streams, just before the spawning season, when it is little inclined to bite, it may be caught by titillation, by passing the hand carefully under

the tail, and, as the tickling is gently performed, slowly moving it toward the head, until by a sudden grasp it is seized and landed; it is also sometimes meanly taken in the spawning season by a large hook fastened to the end of a long stick.—In the genus *salmo* belongs also the char of the British and Swiss lakes (*S. umbla*, Linn.), usually 9 to 12 inches long, but sometimes 18 or 20; it is umber-brown above, the sides lighter with numerous red spots, the lower parts and fins reddish orange; it varies like all other trouts, and occasionally attains a larger size than the above; it frequents the deep part of the lakes, feeds chiefly at night, and affords but little sport to the angler; its American representative is the *S. aquassa* (Girard) of the great lakes of Maine. The northern char (*S. salvelinus*, Linn.), from the lakes of Wales, is another smaller species.—In the genus *salar* (Val.) there are 2 rows of teeth on the vomer. The common European brook trout (*salar fario*, Val.) is usually 10 to 14 inches long, though sometimes considerably larger, even to a weight of 15 lbs.; it is shorter and stouter than the salmon, yellowish brown above, passing to yellow on the sides, and silvery below, the back spotted with reddish brown and the sides with bright red; the young are transversely banded; deformed specimens are frequently seen. The colors are brightest in rapid streams with rocky or gravelly bottom; the flavor of the flesh is finest from the end of May to the end of September, soon after which the spawning season begins. This species is highly prized by anglers, and especially fly-fishers; the caution with which it takes the bait, and its strength and activity when hooked, test the patience and skill of the angler in no small degree; being fond of swiftly running waters, and swimming almost always against the current, the bait must be thrown up stream; it darts with great impetuosity at real or artificial flies; the experienced fisherman knows where to cast his line in deep holes under banks, where it likes to remain quiet and concealed. The eggs are deposited in nests or holes in the sand, as in the salmon. Several allied species are found in the mountain streams and lakes of central and northern Europe. The great gray trout (*S. ferox*, Val.) is of much larger size, but of inferior flavor; it inhabits the deepest lakes; it is purplish brown above, fading to light gray on the sides, and orange yellow below, with a few spots above the lateral line; the flesh is coarse and indifferent, and of an orange yellow color; the females are dark gray above; it attains a length of 2 to 3 feet, and a weight of 20 lbs. and more. The gray trout of the North American great lakes, from the northern United States to the Arctic ocean, is the *S. namaycush* (Val.), and the *salmo amethystus* of Mitchill and De Kay; it is called togue by the Canadian lumbermen, and from its size and voracity the tyrant of the lakes; it is greenish ash above with yellowish gray spots, and below white with bluish re-

flections; the average weight is 12 to 20 lbs, though it attains sometimes more than twice this size. The siskiwit trout (*S. siscowet*, Ag.) belongs to the genus *salar* (Val.); it is of large size, stout and thick, of a rich flavor, but so fat as to be almost unfit for food; for description and figure see Agassiz's "Lake Superior," p. 334 (8vo., Boston, 1850).—The trout, both in Europe and America, is a favorite subject for pisciculture, from the ease with which artificial fecundation of the eggs can be effected; but it has as yet been practised here on a very small scale only; the labor and expense attending a large vivarium of trout are very small, while the remuneration may be made very large.—The reader is referred to Sir Humphry Davy's "Salmonia" for a sportsman's account of scientific fly-fishing for trout.

TROVER (Fr. *trouver*, to find), the name of an action at law in common use in England and in the United States, to determine the ownership of property. The plaintiff declares, in substance, that he was lawfully possessed of a certain article on a certain day, and lost the same; that it came into the possession of the defendant by finding; and that the defendant has refused to deliver it to the plaintiff, and has converted it to his own use. This action is one form of trespass on the case. (See TRESPASS.) In the distant age when it was first used, the declaration may have narrated accurately the facts of the case; but for a long time the losing and finding have been regarded as mere legal fictions, which the defendant is not at liberty to deny. The action is maintainable: 1, where the property in question is a personal chattel; 2, where the plaintiff had a general or special property in the thing with a right of possession; 3, where the defendant has wrongfully converted the thing to his own use, which conversion may be proved by his wrongful taking of it, or his wrongful detention of it, or his wrongful use or misuse of it. The action demands not the thing itself, but damages for the wrongful conversion; and if the plaintiff recovers, the damages should be measured by the value of the thing at the time of the conversion, with interest, and the judgment is for these damages and costs. If the defendant prevails, the judgment is for his costs.

TROWBRIDGE, EDMUND, an American judge, born in Newton, Mass., in 1709, died in Cambridge, Mass., in 1798. He was graduated at Harvard college in 1728, studied law, and rose to great distinction in his profession. In 1749 he was appointed attorney-general, and in 1767 a justice of the supreme court, in which capacity he presided at the trial of Capt. Preston, who commanded the British troops engaged in the "Boston massacre," March 5, 1770. Two years later he left the bench, and until the close of his life lived in retirement. He had the reputation of being the most profound lawyer of his time in New England, and after his retirement occupied himself chiefly in writing essays upon difficult questions of law.

TROY, a city of New York, capital of Rensselaer co., on the E. bank of the Hudson river, at the head of sloop navigation, and also at the head of tide water, in lat. 42° 44' N., long. 73° 40' W., 151 m. N. from New York city, and 6 m. N. from Albany; pop. in 1840, 19,834; in 1850, 28,785; in 1860, 39,235. The surface of the city comprises the alluvial flats $\frac{1}{2}$ of a mile wide on the river, and the hills on the E. known as Mt. Ida. Wynant's Kill on the S., and Poesten Kill at the middle of the city, break through these hills in narrow ravines, and in a series of cascades, the former furnishing 12 mill sites with 2,000 horse power, the latter 10 sites with 1,000 horse power; while the state dam across the Hudson, at the N. part of the city, furnishes 4,000 horse power. Beside these, there is an immense amount of steam power in use. Meadow creek now forms the Hoosic street sewer; and the pure water with which the city is supplied by the Troy water works, is drawn from Piscawin creek into reservoirs which are sufficiently high to carry the water to the top of most of the houses. Protection against fire is afforded by a number of hand fire engines, hose carts, and hook and ladder apparatus, and by 8 first class steam fire engines of great power and capacity. Troy is situated at the principal outlet of the Erie and Champlain canals; and it is connected with Lake Champlain and the north by the Saratoga and Whitehall, Rensselaer and Saratoga, and Troy and Boston railroads, the last named connecting it with the east also; with the west by the New York central railroad; with the south by the Hudson river railroad; and with the east by the western railroad. In the centre of the city is the union railroad depot, built in 1853-'4, one of the largest structures of the kind in the United States, it being 404 by 240 feet, with walls at the sides 27 feet high supporting the roof in a single arch, and a tower 115 feet high. All the railroad lines centre at this depot, and 60 trains arrive at or depart from it daily. The river is spanned by a bridge 1,600 feet long, which is provided with two carriage ways, a railway, and a walk for foot passengers.—The iron manufactures of Troy are of great and increasing importance, and by means of these alone the city has become a controlling point in the iron interest on his side of the Alleghany mountains, and already bears a relation to the country east of these mountains similar to that which Pittsburgh bears to the country west of them. Here are easily, speedily, and cheaply brought the rich magnetic ores of Lake Champlain, and the hematitic ores of the eastern counties of New York and the western counties of Massachusetts, which latter ores possess properties for producing the most superior quality of iron made in the country. The anthracite coal of Pennsylvania is deliverable here by the way of the Delaware and Hudson canal and the Hudson river from Rondout, while the bituminous coals are brought from the Cumberland region by large class sailing vessels, and from Bloss-

burg by rail to Corning, and thence by the Erie canal. Among the largest manufacturing establishments of the country are the Rensselaer iron company, producing rails and merchant iron; the Troy iron and nail factory, producing merchant iron, railway spikes, horse shoes, &c.; and the Albany iron works, situated here, producing merchant iron, nails, railway spikes and chairs, locomotive tires, axles, plates, &c. These establishments consume annually about 75,000 tons of coal and 50,000 tons of iron, employ 1,700 hands, and turn out annually \$3,000,000 worth of goods. The value of the other iron manufactures of the city, carried on by more than 30 firms, and consisting of stoves, hollow ware, hot air furnaces, machinery, steam engines, scythes, shovels, malleable iron, safes, butts, hinges, steel springs, agricultural implements, &c., is of about the same amount. The Troy coach and car factory employs from 200 to 300 workmen, who make from \$300,000 to \$400,000 worth of railroad cars, omnibuses, coaches, &c., annually, which are sent to nearly all parts of the United States, as well as to Cuba and South America. The annual product of the shirt and collar business is \$1,000,000, requiring the labor of 4,500 persons; of flour and grist mills, \$2,000,000; of cotton and woollen mills, \$500,000; of breweries and distilleries, \$700,000; of the lumber trade, \$4,000,000; of miscellaneous manufactures, including clothing, paper and paper hangings, tanneries, boots and shoes, pattern making, carving, &c., \$3,000,000. The state census of 1855 placed the annual product, exclusive of the lumber trade, at \$3,111,847, and the hands employed at 7,469. A careful examination in 1856 showed the annual product, exclusive of the lumber trade, to be \$10,103,000, and the hands 10,032. At the present time the annual product, including the lumber trade, amounts to about \$17,200,000, consummated by the labor of about 12,000 hands. The most extensive mathematical instrument establishment in the United States is in this city, as is also one of the largest of the few American globe manufacturing factories. The amount of the banking capital of Troy is \$3,008,500. The Troy savings bank, established April 23, 1823, is the third savings bank incorporated in the state. The amount of property which reached tide water at Troy by the Erie and Champlain canals in 1860 was 695,780 tons, valued at \$17,043,330; of which 382,466 tons, valued at \$3,811,522, were products of the forest; 446 tons, at \$126,223, of animals; 189,477 tons, at \$7,323,502, of agriculture; 20,289 tons, at \$323,644, of manufactures; 4,515 tons, at \$1,793,587, of merchandise; 148,537 tons, at \$3,664,845, of other articles.—The churches of the city are 33, viz.: 3 Baptist, 1 Congregational, 1 Disciples', 4 Episcopal, 1 Friends', 1 German mission, 1 Jewish, 7 Methodist, 2 Wesleyan Methodist, 5 Presbyterian, 2 Associate Presbyterian, 3 Roman Catholic, 1 Unitarian, and 1 Universalist. The city is divided into 10 wards, each of which elects 2

aldermen, who, with the mayor and recorder, form the common council. The common schools are under the charge of 2 commissioners from each ward. The number of schools is 28, of teachers 104, and of pupils 7,946; the cost of instruction per annum is \$89,071.75. The Troy young men's association for mutual improvement (the second institution of the kind established in the state) has a valuable library of 14,000 volumes, and a reading room provided with 70 newspapers and periodicals, and maintains a course of lectures in the winter. It occupies a part of the beautiful freestone building on First street, known as the Athenæum, in which building the post office, city offices, and 2 banks are also accommodated. The Troy female seminary, situated on Second street, fronting Park place, was founded at Middlebury, Vt., and was removed to Troy in 1821. It has gained a national reputation under the charge of its founder, Mrs. Emma Willard. The Rensselaer polytechnic institute, endowed by Stephen Van Rensselaer, was organized in 1824, for the purpose of teaching the application of mathematics to civil engineering and the natural sciences, and has in its special departments a reputation second only to that of West Point. It has 100 students and 14 teachers. The Troy university, opened in 1858, occupies a commanding position on Mt. Ida, is 259 by 58 feet, and 4 stories high, is built in the Byzantine style, and can accommodate 150 pupils. Other institutions of note are the Marshall infirmary, incorporated in 1851, founded by Benjamin Marshall; the Troy orphan asylum, incorporated April 10, 1835, supported by donations and state appropriations; St. Joseph's academy, which is a free school; St. Mary's orphan asylum, the Troy hospital, and St. Peter's college, all under the charge of the Roman Catholics; and the Warren free institute, a school for indigent female children. The total valuation of property in Troy in 1861 was \$18,079,680, of which \$8,162,500 was real estate, and \$4,917,180 personal property.—The first house of any note on the site of Troy was built by Matthias Vanderheyden in 1752, and is still standing on the S. E. corner of River and Division streets. The dwelling of Jacob I. Vanderheyden, built in 1767, is also standing in the northern part of the city. Between 1786 and 1790 the tract was surveyed and laid out, with streets running at right angles excepting where such plan was interfered with by the course of the river. Hitherto the place had been variously known as Vanderheyden's ferry, Ferry hook, and Ashley's ferry; but on Jan. 5, 1789, the name Troy was adopted at a meeting of the freeholders. At this time the place contained 5 small stores and about a dozen dwellings. Troy was formed as a town, March 18, 1791, and the first village charter was adopted in the same year. This was superseded by another on Feb. 16, 1798, and the village was formally incorporated by state acts passed April 2, 1801, and

April 9, 1805. The city charter was granted April 12, 1816. On June 20, 1820, a fire took place which destroyed property valued at \$490,000, including 93 buildings situated in the thickly populated and business portion of the city. Another fire on Aug. 25, 1854, destroyed property valued at \$1,000,000, including 300 buildings. On May 10, 1862, a conflagration destroyed property valued at \$3,000,000, including 671 buildings, among which was the union railroad depot, the second Presbyterian, United Presbyterian, and North Baptist churches, the free chapel, the Troy orphan asylum, the Warren free institute, the church asylum, the Rensselaer polytechnic institute, the Troy academy, the Troy city bank, the Union house, Washington hall, and the Fulton house. The fire took on the bridge which crosses the Hudson, one half of which was burned, including the draw. Seven lives were lost.

TROY (Τροία), the name of a district in the N. W. part of Mysia in Asia Minor, and of a city situated in it. The latter was also called Ilium, and the former Troas, now the Troad. According to the account of Homer, the city was situated on ground rising above the plain formed by the rivers Scamander and Simois. On the S. E. was a hill, which was a spur of Mt. Ida, and on which were the acropolis of the Trojans called Pergamum, the palaces of the king, and the temples of the gods. No such city as Troy and no such people as the Trojans were known in historic times; but a region called Troas was spoken of by Herodotus and Thucydides, comprising the territory "westward of an imaginary line, drawn from the N. E. corner of the Adramyttian gulf to the Propontis at Parium." There have been various opinions respecting the site of the ancient city, and many efforts made to reconcile the present topography with the geographical statements made in the Homeric poems and other ancient writings, but thus far with but little success. The modern river Mendere, which rises near the summit of Mt. Ida, and runs 40 m. N. W. into the Hellespont, is generally thought to be the Scamander. In the plain its width is from 200 to 300 feet, and it is by far the most important stream in the Troad. The next in size is the Dombek, which is only 12 m. in length, and is considered to be the same as the Simois. These streams formed a junction in the time of Homer, but now enter the Hellespont by different channels. The Ilium of history was founded, according to Strabo, about the beginning of the 7th century B. C., and was inhabited by Æolic Greeks, but, in spite of the reputation of occupying the site of the ancient city, did not become a place of importance until the arrival of the Romans in Asia. They largely augmented its dignity and power, on the supposition that it was the parent of their own city. Demetrius of Scepsis and Hestias took the ground that the Homeric Ilium did not occupy the ground of the more modern city,

but was situated about 4 m. further from it in the direction of Mt. Ida, and at a greater distance from the sea. Although no vestige of the "village of the Ilians" existed, this supposition was adopted by Strabo, and has been admitted without any proof by most modern writers. With the exception of the 8 authors above mentioned, all antiquity seemed to recognize in the site of Ilium the place on which "holy Troy" had once stood, and probably it was the place which Homer had in view. The legend connected with the city was the most wide-spread, the most celebrated, and the most interesting of the Grecian legends, and the only one which represented all Greece as bound together in the unity of a common interest.—Dardanus was the mythical ancestor of the Trojan kings. His son was Erichthonius, who was succeeded by Tros, and he by Ilus, who founded in the plain of Troy the city of Ilium. Ilus was succeeded by Laomedon, and to him Neptune and Apollo became temporarily subject by command of Jupiter. The former built the walls of the city, and the latter took care of the herds; but when their time of service had expired, Laomedon treacherously refused to pay what was due them. In revenge Neptune sent a sea monster to kill the Trojans and ravage their fields, and the treacherous king in consequence made a public offer of the immortal horses given by Jupiter to Tros to any one who could rid the land of the monster. But the oracle declared that a virgin of noble blood must be given up, and the lot fell on Hesione, Laomedon's own daughter. She was rescued however by Hercules, who came at this time and killed the monster. Laomedon gave the hero mortal horses, and the latter, indignant at this perfidy, collected 6 ships, attacked and captured Troy, killed Laomedon, and placed on the throne Priam, who alone of Laomedon's sons had remonstrated against the perfidy of his father. To him were born by his wife Hecuba numerous children, one of whom, Paris, brought on by his abduction of Helen, the wife of Menelaus, the memorable siege of Troy. (See PARIS.) To revenge this outrage, the Greeks spent 10 years in the collection of a vast armament, and at the end of that time a fleet of 1,186 ships, containing more than 100,000 men, was assembled at Aulis in Boeotia, and placed under the command of Agamemnon. The Trojans and their allies were driven within the walls of their city, and 9 years were spent by the Grecian host in the reduction of the neighboring towns. But the gods now brought on the quarrel between Agamemnon and Achilles, which proved so disastrous to the Greeks, and which forms the subject of the Iliad. The Trojans under Hector forced the besiegers to their ships, and killed Patroclus, the intimate friend of Achilles. His death roused Achilles from inactivity, and he once more entered the fight, drove the Trojans within their walls, and killed their bravest leader, Hector. Later legends recount that after his death the

inhabitants of the city were encouraged by the arrival of Penthesileia, the beautiful queen of the Amazons, under whom they were for a time successful, but she was also slain by Achilles. Memnon next came to the aid of the Trojans, with a band of Ethiopians, and under his lead the Greeks were again driven back. A long and doubtful combat ensued between him and Achilles, but at last the Greek champion triumphed. His own time, however, was near at hand; he was slain, according to non-Homeric tradition, at the Scæan gate by an arrow from the quiver of Paris. Philoctetes and Neoptolemus, the sons of Achilles, were summoned to the aid of the besieging army; and at length, by the stratagem of a wooden horse filled with men, which the Trojans incautiously drew into the city, Ilium was taken. Troy was utterly destroyed, Æneas and Antenor alone being suffered to escape with their families.—The legend of Troy was universally believed by the ancients; and the credibility to be attached to it or to any part of it has been the subject of fierce disputes among modern writers. Toward the end of the last century Le Chevalier published an account of the plain of Troy, in which he professed to have found the site of the ancient city, and a controversy sprang up in consequence between Bryant and Morritt, Gilbert Wakefield, and others. Bryant contended that there was no such city as Troy, and no such war as the Trojan; while his opponents held that a basis of truth is not to be rejected because a superstructure of fiction has been erected upon it, and that the universal belief of antiquity was a proof that there was such a war.

TROY WEIGHT, a scale of weights used in England and the United States for weighing gold, silver, and jewels, and in trying the strength of spirituous liquors, and legally established in both for determining the weight of coins. By some, the name of troy weight is supposed to be derived from Troyes in France, the weight being brought thither from Cairo during the crusades, and thence taken to England by the goldsmiths. Others derive the name from Troy Novant, an ancient designation of London; and others from *trois*, three, with reference to the three principal divisions of penny, shilling, and pound, or penny, ounce, and pound, used in money weight. In 1828 a standard troy pound in brass brought from England was declared by act of congress the legal standard of the U. S. mint. According to Hassler, it is equal in weight to 22,794,877 cubic inches of distilled water. It contains 5,760 grains, of which 24 make 1 pennyweight, 20 pennyweights an ounce, and 12 ounces a pound. The weight of this compared with the avoirdupois pound is as 5,760 to 7,000, or as 144 to 175. (See AVOIRDUPOIS.) It is identical with the pound of apothecary's weight, and the ounce and grain of these two weights are also correspondingly the same. The pennyweight subdivision of troy weight, determining the

weight of the silver penny, was established in 1256, as equal to the weight of 32 grains of wheat taken from the middle of the ear. As the kings of later times found it expedient to reduce the value of the penny, this reduction was accompanied by a proportional diminution in the number of grains of which it was composed. A troy weight was established in 1618 by James VI. of Scotland, the pound of which weighed 1.328 pounds troy. This is now abolished by law.

TROYES (anc. *Civitas Tricassium*), a town of France, capital of the department of Aube, situated on the left bank of the Seine, 90 m. E. S. E. from Paris; pop. in 1856, 30,966. The houses have a very antiquated appearance, many of them being made of timber and plaster; but in some quarters these have been replaced by modern buildings. The cathedral, commenced in the 13th century and finished in the 16th, is a fine specimen of the florid Gothic style, with stained glass windows of great beauty. There are several other churches, some of which are very richly decorated. There is a public library containing 55,000 volumes and 5,000 MSS., and numerous schools and scientific and literary societies. Woollen and cotton goods, leather, paper, oil, and wax are manufactured, and there are extensive breweries. Troyes is connected with Paris by railroad.—The town was founded during the occupation of Gaul by the Romans, and in 889 it was burned by the Normans. In 1415 the duke of Burgundy captured it; and 5 years afterward Henry V. of England was married at Troyes to Catharine of France. In 1429 the French, headed by Joan of Arc, expelled the English. In the middle ages great fairs were held here, and the weight called troy, according to some, takes its name from this town. During the last struggles of Napoleon in 1814 his head-quarters were fixed at Troyes, and the town was twice captured by the allies, being once recaptured by the French.

TRUCE OF GOD (Lat. *Tregua Dei* or *Treuga Dei*, from Ger. *Treue*, faith), an institution of the middle ages, designed to mitigate the violence of private war by prohibiting engagement in hostilities, at least on the holy days, from Thursday evening to Sunday evening of each week, also during the entire season of Advent and Lent, and on certain festival days. The days of the week were selected because they were supposed to be rendered holy by the death and resurrection of our Lord. It was an effort made by the church to render less injurious the effects of an evil which it could not wholly root out. This salutary regulation was introduced in the first part of the 11th century, after the great famine of 1028-'30, by the bishops of Aquitaine, who proclaimed a universal peace. But as, on account of the martial spirit of the people, it was found impossible to enforce this, they were obliged to limit it to certain days, and thus arose the truce of God in its peculiar sense. The regulation soon spread over all France; and according to its terms, all unarmed per-

sons, such as priests, monks, nuns, merchants, women, pilgrims, and cultivators of the soil, enjoyed an undisturbed peace. In 1041 the Aquitanian bishops ordered that no private feuds should be prosecuted from sunset on Wednesday to sunrise on Monday of the following week. This was extended by the council of Clermont to the time from Advent to Epiphany, from Lent to 8 days after Pentecost (Whitsuntide), and not long afterward to the days on which were celebrated the feasts of the Blessed Virgin, of John the Baptist, of the Apostles Peter and Paul, and of All Saints, and the eves of those days. Calixtus II. at the council of Rheims in 1136, renewed in the strongest language the truce of God, commanding war to cease on the above mentioned times throughout Christendom, and all violators were to be excommunicated every Sunday in every parish church, and, unless satisfaction were given either by themselves or by their children, were to be deemed unworthy of Christian burial. Yet in spite of these stern penalties, there is no doubt that the regulation was often violated, and the records of the councils and the chronicles of convents record many such cases. It was however extended over all the dioceses and provinces in England, France, Italy, and Germany. Wednesday was not usually included. When the states of Europe began to assume a more consolidated form, and violations of peace and order came under the control of the civil authority, the truce of God disappeared.

TRUFFLE, a subterranean fungus, of which there are many kinds, some of which are in great request for seasoning food. The ancients seem to have been familiar with truffles, and they are described under the name of *idæum* by Theophrastus. The common truffle (*tuber cibarium*, Sibthorp) is of an irregular globular form, having a hard black or dark brown cracked rind, roughened into protuberances; within, its texture is netted or veiny with white and dark lines so as to present a marbled appearance, or else a mottled one like the nutmeg. Neither root, stem, nor other appendage is to be seen in the mature truffle, but it lies in the cavity which it forms in the earth by the increasing lateral pressure of its growth, varying in size from that of a bean to that of a walnut or Madeira nut, and found 10 to 12 inches below the surface. The veiny lines of the interior constitute the hymenium, and by combination furnish irregularly distributed hollows (*asci*), in which the seed-like bodies (*spores*), covered by a cellular envelope (*epispore*), are lodged. This structure is however only a modification of one belonging to a large family of fungi, conspicuous for the evolution of its organs of fructification and its hymenium which accompanies them being plainly exposed to view, and therefore by contrast rendering the hypogæous or underground truffles (*tuberæcæ*) strikingly peculiar. The flesh of the truffle is solid, somewhat juicy, and when ripe of a sharp fragrant odor, different species however pos-

possessing different flavors of taste and smell. A moist, light, vegetable mould, in young woods or under the shade of large solitary trees, especially of beech and oak, is favorable to their growth, but the subsoil should be calcareous. The species have been found in various parts of the world, and in certain districts of Europe they especially abound; but in the United States they occur but rarely. Such is the esteem in which they are held, that dogs are trained to hunt for them and dig them out of the ground, and many persons employ themselves in the pursuit as a regular occupation. When the air is moist, and just before a thunder shower, they are said to emit a peculiar odor which facilitates the search. The species mostly sold in the English market is the *tuber aestivum*; but in France higher and more delicious-flavored species, such as the *T. magnatum* and *melanosporum*, are commonly consumed. Several species of insects greedily feed upon them. The white truffle (*rhizopogon albus*, Bulliard) is round, rather rough, at first white, then reddish brown, and slightly fibrillose at base, from which circumstance it is called root-beard by some writers. It grows in woods in sandy soils, raising itself partially above the surface, in which it differs from the truffle, which is wholly concealed. Schweinitz gives 3 species observed in Pennsylvania and North Carolina, and mentions the frequent occurrence of the common truffle in the former state.—The artificial culture of truffles is not so easy as that of mushrooms; and great care is requisite to fit the soil for even successful transplanting. In countries where they are indigenous, as in the calcareous districts of France, the simple enclosure of a piece of ground and planting it with young oaks will encourage their appearance after a few years.—The *tuberacea*, of which the truffle is the type, as subjects for investigation, present unusual attractions to the student in structural botany, and in the employment of the microscope.

TRUMBULL, a N. E. co. of Ohio, bordering on Pennsylvania, intersected by Grand and Mahoning rivers; area, 625 sq. m.; pop. in 1860, 30,656. The surface is undulating and well timbered, and the soil fertile and adapted to dairy farming. The productions in 1850 were 121,068 bushels of wheat, 302,906 of Indian corn, 235,048 of oats, 64,116 tons of hay, 4,852,942 lbs. of cheese, 710,118 of butter, and 208,055 of wool. There were 16 grist mills, 44 saw mills, 4 foundries, 5 woollen factories, 10 tanneries, 78 churches, 3 newspaper offices, and 14,904 pupils attending public schools. It is intersected by the Cleveland and Mahoning railroad and the Pennsylvania and Ohio canal, and Pymatuning swamp occupies part of the county. Capital, Warren.

TRUMBULL, BENJAMIN, D.D., an American clergyman and historian, born in Hebron, Conn., Dec. 19, 1735, died in North Haven, Conn., Feb. 2, 1820. He was graduated at Yale college in 1759, was employed for some time

as a teacher in Dr. Wheelock's Indian charity school in Lebanon, and in 1760 became pastor of the Congregational church at North Haven, Conn. He took an active part in the war of the revolution, not only serving as a chaplain, but volunteering as a soldier. After the war, a large tract of land, known as the "Susquehanna purchase," was claimed by both Connecticut and Pennsylvania; and the conflicting claims occasioned no small disquietude. Mr. Trumbull published a pamphlet on the subject which is said to have been chiefly instrumental in leading congress to acknowledge the claim of Connecticut. He possessed great physical as well as mental vigor, and until he had reached his 85th year his power of endurance had scarcely begun to wane. Beside about a dozen occasional sermons and several controversial pamphlets, he published 12 "Discourses on the Divine Origin of the Scriptures," a "History of Connecticut" (2 vols. 8vo., 1797 and 1818), and a "History of the United States" (8vo., 1810). He bequeathed his MSS. to the library of Yale college.

TRUMBULL, JOHN, LL.D., an American poet, born in Watertown, Conn., April 24, 1750, died in Detroit, May 12, 1831. He passed satisfactorily an examination for admission into Yale college at the age of 7 years, though he did not actually enter it until 6 years later, studying in the mean time the English classics. He was graduated in 1767, and became a tutor in 1771, together with Timothy Dwight, his fellow student, with whom he was associated in writing for the newspapers. In 1773 he was admitted to the bar in Connecticut, but continued the study of law in the office of John Adams at Boston. At the end of 1774 he returned to New Haven, where he remained until 1781, when he took up his residence at Hartford, and there became distinguished in his profession. He was a member of the state legislature, and from 1801 to 1819 a judge of the superior court of the state. In 1825 he removed to Detroit, where the rest of his life was spent. Of his "Poetical Works" (2 vols., Hartford, 1820), the revolutionary satire "McFingal" only is now quoted. This humorous epic, professedly on the model of Hudibras, was so popular upon its original publication that over 30 unauthorized editions of it were sold. It gives a general account of the revolutionary contest in burlesque, with particular descriptions of characters and manners, and satirical sketches of the follies and extravagances on both sides. His principal other poem is "The Progress of Dullness," in 3 parts, the first of which was published in 1772, and the 2d and 3d in 1778.

TRUMBULL, I. JONATHAN, an American colonial governor, born in Lebanon, Conn., in 1710, died Aug. 17, 1785. He was graduated at Harvard college in 1727, subsequently devoted himself to mercantile pursuits, and in 1766, having previously been for many years a member of the Connecticut assembly, was elected lieutenant-governor. He early espoused the

popular cause, and, having refused in 1768 to take the oath of office enjoined by parliament, was in 1769 chosen governor, to which office he was reelected for 14 consecutive years. He was a man of great integrity, and cooperated with vigor in securing the independence of the colonies. Washington relied on him, says Sparks, "as one of his main pillars of support," and was accustomed to consult him in emergencies. The generic name humorously applied to the United States is said to have had its origin in a phrase sometimes used by Washington: "Let us hear what brother Jonathan says." A memoir of him has been published by Isaac Stuart.

II. JONATHAN, son of the preceding, born in Lebanon, Conn., March 26, 1740, died Aug. 7, 1809. He was graduated at Harvard college in 1759, and at the outbreak of the revolution received from congress the appointment of paymaster to the northern department of the army, which he held until the close of the campaign of 1778, when he entered the military family of Washington as secretary and first aide-de-camp. He enjoyed in this capacity the confidence and esteem of the commander-in-chief, with whom he remained until the close of the war. He was elected a member of congress in 1789, and presided as speaker over the 2d congress, 1791-'3. In 1795 he was transferred to the U. S. senate, and in 1796 elected lieutenant-governor of Connecticut. Two years later he was made governor of the state, which position he filled until his death.

III. JOHN, an American painter, brother of the preceding, born in Lebanon, Conn., June 6, 1756, died in New York, Nov. 10, 1848. He was graduated at Harvard college in 1773, and soon after devoted himself to the study of painting, his natural taste for which was stimulated by the contemplation of the works of Smibert and Copley in Boston. He had finished two original pictures, the "Battle of Cannæ" and the "Judgment of Brutus," when the breaking out of the revolutionary war called him to active duties in the field; and in the spring of 1775 he joined the army of the colonies before Boston in the capacity of adjutant of the 1st Connecticut regiment, being then only 19 years of age. His skill in drawing soon procured him from Washington a commission to prepare a plan of the enemy's works; and in return for the able manner in which he executed this task he was, in Aug. 1775, appointed aide-de-camp to the commander-in-chief, and shortly after brigade major. He accompanied the army to New York, and in June, 1776, departed northward with Gen. Gates, with the rank of colonel and adjutant-general. He held this office under Gates, and subsequently under Arnold, until the spring of 1777, when, taking umbrage at the action of congress with reference to the date of his commission, he left the service, and resumed the study of painting. In May, 1780, he embarked for France, and, proceeding thence to London, was kindly received by Benjamin

West, under whose instructions he was making rapid progress in his art, when the excitement occasioned by the execution of Major André led to his arrest and imprisonment. West, who was at that time painter in ordinary to George III. and in friendly relations with the king, interceded in behalf of his pupil, and received the royal assurance "that in the worst possible event of the law his life would be safe." Trumbull, however, suffered a confinement of 8 months, which he employed to advantage in study, and was finally admitted to bail by a special order of the king in council on condition of quitting the kingdom within 30 days, West and Copley becoming his sureties. He returned home in Jan. 1783, but revisited England after the conclusion of peace, and resumed his studies under West. One of his first original works, "Priam receiving the Body of Hector," is now in the possession of the Boston Athenæum. In 1786 he produced his first modern historical work, the "Battle of Bunker Hill," followed soon after by the "Death of Montgomery before Quebec," both of which attracted considerable attention. The first, valuable, as are all Trumbull's historical pictures, for its portraits, is one of the most spirited battle pieces ever painted, and was admirably engraved by J. G. Müller of Stuttgart. The second picture was engraved by the Danish engraver F. Clemens in London, and for both prints Trumbull had numerous subscribers in Europe and America. Finding that these works were not altogether of a character to please the British public, he chose for his next subject the "Sortie of the Garrison from Gibraltar" during the memorable siege by the French and Spanish armies, one of the repetitions of which is now the property of the Boston Athenæum. The finished picture, 6 feet by 9 in dimensions, was exhibited with great success in Spring Garden, London, in 1789, and is widely known through the engraving by Sharp. In the autumn of 1789 he returned to America to procure likenesses of distinguished patriots for a contemplated series of national pictures commemorating the principal events of the revolutionary struggle; and while thus engaged he painted several portraits of Washington, one of which, a full-length figure in uniform, is in the collection of the corporation of New York city. Having accomplished his object, he went in 1794 to England as secretary to Mr. Jay, the American minister; and in Aug. 1796, he was appointed 5th commissioner for the execution of the 7th article of Mr. Jay's treaty of 1794, the duties of which office occupied him until 1804, when he returned to the United States. In 1806 he was again in England, and during an uninterrupted residence there of 7 years executed a number of pictures, which met with indifferent success. After his return to the United States in 1815 he never again quitted the country. In 1817 he was authorized by congress to fill 4 compartments of the rotunda in the new capitol with pictures, each 18 feet

by 12, illustrating the history of the nation; and during the next 7 years he was chiefly employed in this undertaking, for which he received the sum of \$32,000. These works, representing the "Declaration of Independence," the "Surrender of Burgoyne," the "Surrender of Cornwallis," and the "Resignation of General Washington at Annapolis, Dec. 23, 1783," are executed in the style of West, and, apart from their value as collections of authentic portraits, are considered to have little merit. Subsequently for many years he was employed in finishing his former sketches, and in painting copies of his national pictures on a uniform scale of 6 feet by 9; and finding that neither government nor any individual was likely to purchase the series, he concluded an arrangement with Yale college, by which, in consideration of an annuity of \$1,000 for the remainder of his life, the whole collection was transferred to that institution, and deposited in a fire-proof building erected especially for their reception. The "Trumbull gallery," as it is called, beside copies of most of the historical pictures above mentioned, contains the "Battle of Princeton," partly finished, the "Surrender of the Hessians at Trenton," the "Death of Mercer at Princeton," a portrait of Washington painted in 1792 for the city of Charleston, "The Woman taken in Adultery," "Suffer Little Children to Come unto Me," painted during his last residence in England, copies of several works of the old masters, &c.—in all, 57 pictures. It is the largest and most interesting collection extant of the productions of any American painter. With the exception of the interval between 1837 and 1841, he passed the last 27 years of his life in the city of New York, and was the president of the American academy of fine arts from its foundation in 1816 until the formation of the national academy of design in 1825. In this capacity he afforded instructions in painting to numerous pupils.

TRUMPET, a musical wind instrument of brass or other metal, which under one form or another has been known in all ages and among all races having any claim to civilization. The term is so vaguely used that it is sometimes regarded as generic merely, and comprehending the whole family of metallic instruments; but the trumpet, so called in modern use, is generally understood as a tube 8 feet in length, expanding at the end whence the sound issues into a bell-like shape, and doubled up in a parabolic form. It is played through a mouth-piece, and has a natural compass from G below the staff to E above.

TRUMPET, HEARING. See **EAR TRUMPET**.

TRUMPET, SPEAKING. See **SPEAKING TRUMPET**.

TRUMPET FISH. See **PIPE FISH**.

TRUMPET FLOWER, a familiar name of several species of the bignoniads of the natural order of *bignoniaceae*. They are usually twining or climbing shrubs, with opposite compound leaves, without stipules; flowers with

2-lipped, 5-lobed calyx; tubular or bell-shaped corolla, and 5 unequal stamens, 2 to 4 of which are fertile; 2-celled, many-ovuled ovary, 2-lipped filiform style, and 2 to 4-celled, many-seeded capsule. The tendrilled trumpet flower (*bignonia capreolata*, Linn.) has a high climbing stem, evergreen leaves, the short petiole terminating at the apex of the leaf in a branched tendril, the leaflets ovate, cordate, acuminate, the flowers monopetalous and bell-shaped, with a tube 2 inches long and an outspread divided rim, of a red color without and yellow within. It climbs over trees and shrubs, and is found in the woods from Virginia to Florida, blossoming in April. The name of crosswood is given to this species, on account of the woody portion of its stem being subdivided into 4 cruciform lobes. The hardiest of the trumpet flowers is the *tecoma radicans* (Jussieu), a luxuriant ornamental vine attaching itself firmly to trees, houses, and other structures by means of rootlets which issue from the stems, and climbing to great heights in a single season. Its leaves are pinnate, the leaflets somewhat ribbed, smooth above, pubescent beneath, the flowers in a sort of raceme, large, 2 to 3 inches long, of a scarlet color, but yellowish within, succeeded by very long, terete, silique-like capsules filled with winged seeds. There are some varieties of this species, of which the *T. r.* var. *atropurpurea* is considered the finest, having elegantly winged leaves and conspicuous flowers of an orange-red color tinged with violet purple. The erect trumpet flower (*T. stans*, Juss.) has smooth, pinnate, long-petioled leaves of 7 leaflets, many-flowered racemes, the flowers with tubular calyx, long, yellow corolla, and 5 stamens, the 5th one abortive; it occurs in southern Florida, blooming there from March to May. There are several other species which require artificial heat to perfect them, such as the *bignonia venusta* (Bot. Reg.), a native of South America, and one of the most splendid of hot-house creepers. Its stems are long, slender, dark gray, and pliant; its leaves ternate, but in pairs on the terminal branches, each leaflet being thin, smooth, acuminate-ovate, of a rich green; the flowers in numerous corymba, of a rich vermilion-orange and trumpet-shaped. It requires continuous gentle heat at its roots, and pruning after the wood has ripened. By allowing it to rest from April to September, its blossoms appear from November to the following spring. The jasmine-scented trumpet flower is the *tecoma jasmínoides*, a handsome evergreen climber, well suited to the greenhouse or conservatory, its leaves being bright green with ovate leaflets, its flowers produced on long terminal racemes, funnel-shaped, each 2 inches long, pure white, with a rosy throat; a variety known as the *rosea* is a better bloomer and its throat more deeply tinted. The large-flowered trumpet flower (*T. grandiflora*) is a highly ornamental species; its leaves are deciduous, elegantly winged or pinnate, 12

inches in length; the flower panicles terminal, wide-branching; each flower large, broad-limbed, trumpet-shaped, 8 to 4 inches wide, and of a bright red-orange. Where the climate permits, it becomes magnificent in outdoor culture trained upon a wall.—The bignoniads are readily raised from seeds, layers, and cuttings. Several are employed economically, as the *B. chica*, whose leaves boiled in water give a feculent red substance important to dyers, and imparting an orange-red color to cotton. The tough shoots of *B. chirere* are woven into wickerwork. Several species abound in tannin, and bitter and mucilaginous principles, or possess cathartic and diuretic properties; a Brazilian species is employed in treatment of syphilis; the roots of others are poisonous as well as bitter. Some are large trees, valuable for timber.

TRUMPETER, in ornithology. See AGAM.

TRUNK FISH, the very appropriate name of the plectognathous fishes of the genus *ostracion* (Linn.), derived from the bony case in which their soft parts are enclosed; they are also called coffer fishes. The head is prolonged into a snout, at the end of which is the mouth, with fleshy lips, and armed with a series of distinct teeth, 10 or 12 in each jaw, received into sockets, somewhat like the human incisors; body covered by bony plates, large, quadrangular or hexagonal, encasing the animal in an inflexible bony armor; tail enclosed in a bony tube, this and the pectoral fins being the only movable parts; even the vertebræ are usually immovable; eyes large and prominent; dorsal single, far back, small, and entirely soft; pelvic bones and ventrals absent; body 8 or 4 sided, with linear branchial openings, bordered by a fleshy edge within which are the gill covers; they have very little flesh, and some are believed to be poisonous; the stomach is membranous and very large; the liver is also large, often yielding a considerable quantity of oil; some are armed with spines on the head and body; they are generally of small size, and found in the tropics, whence they sometimes wander to temperate zones. There are a few species on the coast of the United States, arranged by De Kay in his genus *lactophrys*, having a triangular body, with strong spines, directed backward, in front of the anal fin, and the orbits usually spinotus. The 6-horned trunk fish (*O. [L.] sex-cornutus*, Mitch.), from the gulf of Mexico, is 7 inches long, with 2 spines on the head and 4 on the abdomen; it is clouded with brown above, and white below. Yale's trunk fish (*O. [L.] Yalei*, Storer), on the coast of Massachusetts and New York, is 14 inches long, with 2 abdominal spines. The *O. triquetrum* (Linn.), or triangular trunk fish, from the West Indies, is 12 inches long, without spines, reddish brown with a white spot in the centre of each hexagonal plate. There are other species in the East Indies.

TRURO, THOMAS WILDE, baron, an English statesman and jurist, born July 7, 1782, died at

Bowes Manor, Middlesex, Nov. 11, 1855. He was the son of a solicitor in London, and after a preliminary career as an attorney was in 1817 called to the bar, and rose to such eminence in his profession, that in 1820 he was employed as one of the junior counsel for the defence in the trial of Queen Caroline. In 1824 he was made sergeant at law, in 1827 king's sergeant, in 1839 solicitor-general, and in 1841 attorney-general. Upon the return of the whigs to power in 1846, he was appointed chief justice of the court of common pleas, and in 1850 lord chancellor, on which latter occasion he was raised to the peerage as Baron Truro. He retired from office in 1853 on a change of ministry. He was an able, impartial, and industrious judge, and accomplished several much needed reforms in the procedure of the courts of chancery and common law.

TRUSS, a contrivance for preventing the reappearance of a hernial tumor after its reduction. The general form of the truss is a flat steel spring covered with soft leather or oiled silk, and having its ends approximating to within a few inches of each other; attached to one end is a small round or oval pad, stuffed with cotton or wool, and having for its basis a small iron plate; the other end of the spring has either a larger and flat pad, or a strap connected with it. The smaller pad is placed over the ring or point where the hernial tumor has protruded (see HERNIA), and the spring passes over the hip, and either exerts its pressure by means of the large counter pad on the back, or is by means of a strap passing over the opposite hip connected with the pad by a buckle or eyelet and button on the back of the pad. Sometimes, where it is necessary to adjust it with great care, another strap passing over the inner surface of the thigh connects with the spring on the back. Where, as is sometimes the case, there is a double hernia, this spring is made sufficiently long to clasp over both hips, and has a pad at each end. In this case there should be a pad attached to the middle of the spring to exert gentle pressure on the spine, and thus keep the truss more perfectly in position. There are numerous patterns of trusses, varying considerably in form; they may all, however, be reduced to 3 classes: those with a flat pad, intended to press upon the whole surface of the ring or place through which the intestine protrudes; the oval or egg-shaped pad, which presses directly into the ring, and thus prevents the escape of the intestine; and the semicircular pad, which acts by supporting the intestine from above and pressing it away from the point of rupture. The truss, though preventing the recurrence of the hernial tumor when properly adjusted, seldom effects a radical cure. This has, however, been attempted, by purposely so adjusting it as to cause it to produce some inflammation and adhesion of the serous surface around the ring so as to produce complete occlusion of it; but it should never be done except under the direc-

on of a skilful physician, as it is attended with anger.

TRUSTS. It is quite certain that trusts, which have now such immense importance in the law and the disposition of property in England and in the United States, originated in fraud. The feudal law of tenures embarrassed owners of property in their disposal of it, and the statutes of mortmain obstructed the appropriation at the pleasure of the owner still more; and it was to evade these rules of law, that trusts (or the granting of property in trust) were invented. As the common law took no cognizance of trusts, they came before a court of equity. And if we remember that the chancellor was in early times usually a priest, and that the statutes of mortmain, which trusts were invented to evade, restricted or prohibited the granting of property to religious communities, we can understand why the court of equity took them under its protection. It did this by summoning the trustee before it, and compelling him "to do what justice and equity required." Hence Sir Robert Mordaunt, in the reign of Charles II., said: "A trust had for its parents fraud and fear, and for its nurse a court of conscience." The way in which these laws were successfully evaded by trusts was this. If property is given to A. B., with all the forms of law, and in the same manner as if it were to be absolutely his own, but in fact for the use and benefit of C. D., the common law knows no one but A. B.; all the title is in him, and the estate in him is protected against all forfeitures but those which attach to him. But C. D. has all the benefit and advantage of the property. Hence if C. D. were a traitor, who would have forfeited the state had it been his in law, or a religious body who could not take the estate by law, A. B. still might hold it for the benefit of C. D. In this way fraud and fear were the parents of trusts. But as the law knew no estate or title but that of A. B., if he chose to be dishonest, and to refuse all benefit of the trust to C. D., there was no remedy at law, and the trust would have been defeated. Then the court of equity came in, and, by compelling A. B. to perform the trust he had undertaken, became the nurse of this child of fraud. Now, however, trusts are employed in a vast number of cases, most honestly and beneficially, wherever it is desired to give any person the benefit and use of property, but to keep from him or her all power of forfeiting or alienating it. The greatest number of modern trusts are created either by will or by transfer *inter vivos* to protect the estates of women from the control or the creditors of their husbands, or to carry down property to a series of holders, in some other way than that which would be provided by the laws of inheritance or distribution. To all trusts there are therefore two parties. One of these holds the legal title to the estate, and he is called trustee; the other is the party who has the actual benefit of the

trust, and who is called, by a Norman French phrase, the *cestuy que trust*. As the trustee has all the title which a court of law can recognize, he is said to have the legal estate; and as the *cestuy que trust* has an interest which only a court of equity can recognize and protect, he is said to have an equitable estate. At present, however, when the courts of law and the rules of law are coming nearer to the courts and the rules of equity, the antagonism between these has passed away, and the distinction becomes much less important. There may be any number of trustees and any number of *cestuy que trusts* in any trust. If the trustee holds the property for the benefit of the *cestuy que trust* without any particular restrictions, directions, or provisions, it is called a simple trust; and then the nature and operation of the trust are determined by legal or equitable construction. But if the purposes of the trust, and the manner in which and the means by which these purposes shall be accomplished, are specifically pointed out and defined, it is then a special trust, and these special directions must be accurately complied with. Hence a trust may be merely ministerial; and it is so called when the trustee has no other duty than to collect and pay over the proceeds of property. Or it may be a discretionary trust, and is so when the general purpose only is declared, and the manner in which this purpose shall be accomplished is left to the discretion of the trustee. So a trust may have a power annexed; as when a trustee of lands has the power of leasing, or even of selling and converting them into personal property. And indeed any lawful powers may be given to a trustee. There are also private trustees and public trustees. The former hold property for one or more individuals, who are distinctly pointed out, personally or by description. Public trustees are those who hold property for the benefit of the whole public, or for a certain large part of it, as a county, town, or parish. They are regarded by the law as in many respects official persons, with official rights and responsibilities.—The subject matter of a trust may be any property of a valuable nature, and many things also which the common law does not recognize as disposable or assignable property; as choses in action and probabilities of every description, or mere authorities which may be or become valuable. Even if the property be in another state or country, so that the process of the court could not reach it, yet it is now settled that a court of equity in any of the United States will interfere in any case of trust, however distant or inaccessible the property may be, provided the principal defendants are actually served with process, and adequate relief may be given by a decree *in personam*.—As to the capacity of creating a trust, it may be said that any person who has the power of making a valid disposition of any property, by will or grant, has also the power of attaching to his or her disposition of the property such limitations or

directions as shall create a trust, and make the person who takes the legal estate in the property a trustee for the persons to whom the beneficial interest is given. Even if the property is transferred and the trust created by one who does not hold it with a complete power of final disposition, as a married woman or an infant, yet the trust will be valid and protected so far as the subject matter of it is within their power of conveyance.—It may be said, as a general rule, that any person may be a trustee, even if he be incapacitated by law from transacting business on his own account. Thus infants, idiots, lunatics, married women, or other persons *non sui juris*, may become trustees. The reason is, that the trust is created for the benefit of the *cestui que trust*, and not of the trustee; and if the trustee cannot take the legal estate, there will be nothing to support the equitable estate, and the trust will fail. So, too, it is established doctrine that a trust once created shall never fail on account of the death of a trustee, or his refusal to accept the trust. All difficulties of this kind are avoided by the power of the proper court (usually the court of equity) to remove a trustee and supply his place, or fill the place of a trustee when vacant by his death or refusal. And, in general, it may be said that the appropriate court in England and in the United States has full power to do whatever may be necessary, by way of removal, substitution, or appointment, to sustain and effectuate a trust. It is a very common thing for a will or deed creating a trust to prescribe in what way and by what person or tribunal this power may be exercised; and provisions to this effect would doubtless be regarded when they did not contravene the general principles of the law, or the statutory provisions in behalf of trusts and trustees. It may be added that any person in possession of property, real or personal, by legal title and of his own right, may, by a proper declaration of trust, convert himself into a trustee, and then his legal title will remain undisturbed, but subjected to the equitable interest.—Any person may become a *cestui que trust* of property, to the extent of his legal capacity of holding the same. Nor is it necessary to the creation of a trust estate, that the *cestui que trust* should be named, or even that he should be in being when the trust is created. Thus money may be bequeathed or given to a trustee for any children that a certain person may have living at his death, and to accumulate until the death of that person. The assent of the *cestui que trust*, if he is capable of giving one, is, strictly speaking, necessary; but it will be presumed where the trust is beneficial to him. It is now a common practice to permit societies and institutions to take the benefit of a trust, which are not incorporated and therefore not recognized by the law; but they must be definitely described, and capable of certain identification.—Trusts and uses (see Uses) were originally created and declared principal-

ly, if not exclusively, by parol; but this was because they were then intended to evade the law. Now, it is uncertain whether trusts, especially trusts of real estate, can be created except in writing, and for some purposes by deed. We should say that most of our courts of equity might recognize and protect trusts created by parol, if they were sufficiently definite and certain as to their terms, and the subject matter and the persons thereof, although created only by parol, and even in some cases where a statutory provision required writing or a deed. In most of the United States, the provisions of the English statute of frauds, requiring trusts to be in writing, have been reenacted. In England, however, courts of equity have given a very liberal construction to these provisions, and a similar construction might be expected here. Where a trust is created, if at all, by a writing, especially if that writing be a will, any direct fiduciary expressions, indicative of a purpose that the donee of the property is to take it, in whole or in part, for the benefit, use, advantage, or support of another, will be held sufficient to create a trust. Seldom are particular words required in equity, and even Lord Eldon has said that the absence of the word "trust" is a circumstance to be attended to, but nothing more. But such words or directions must be imperative on the donee; if they, by fair construction, only give him a power or permission, or even express a desire which is not obligatory on him, they do not create a trust. If however the trust is distinctly and positively created, although no *cestui que trust* is designated, the courts will enforce the trust for the benefit of those who may take by disposition of the law. If the donee may at his own discretion or pleasure execute the alleged trust or not, it is not a trust; but it is a valid trust if he must execute the trust, although the manner of doing it is entirely at his discretion. So, too, there may be what are called "resulting" or "presumptive trusts," which are expressed nowhere, but are implied or presumed from the assumed intention of the parties, or arise from the nature of the transaction; and the statute of frauds expressly excepts these trusts from the requirement of writing.—It is sometimes important to determine whether a trustee accepts the trust. He is always at liberty to decline it, but he cannot take the property without the trust. As every trust confers the legal title on the trustee, there is a presumption similar to that already mentioned in reference to the *cestui que trust*, namely, that it is for his benefit, and therefore his acceptance will be presumed. But the presumption is of much less weight than in the case of the *cestui que trust*, because if a trustee take the property at all, he takes it *cum onere*, and the burden may be very heavy. Properly, therefore, the best if not the only evidence of an acceptance of the trust is some action by the trustee under it. The same person may stand in different relations; thus he may be appointed executor and also

trustee; and he may give separate bonds with different sureties, as executor and as trustee. In such cases it is sometimes difficult to say where the duty and responsibility of executor end and those of trustee begin. The general rule is this: If the executor has specifically set apart a portion of the estate to the purpose of the trust, he will be considered as to that portion as having discharged his duty as executor and entered upon his duty as trustee.—An important doctrine of the law of trusts, familiar to English lawyers and frequently applied in English courts, is known by the name of the *quasi-trust* doctrine. This phrase means literally "near to it;" and this doctrine is applied when a trust is certainly created, and it is impossible to execute it precisely as the donor prescribed, and then a court of equity, from its desire to sustain the trust, will direct an exercise of it as near as possible to the original intention of the donor. By far the most frequent occasion for its application arises from the change of circumstances in ancient trusts; as, for example, where there is an endowment for a school limited to scholars of a certain description, and here are not now any scholars of that description. But that necessity cannot exist so frequently or with so much force in the United States as in England. As an undefined judicial power, it is open to abuse, and is, if not denied or disclaimed, exercised with great forbearance in the United States.—Trustees are held, both in England and in this country, to a somewhat strict accountability. A trustee is bound not only to guard against loss or damage to the trust property, but to see that it is made reasonably productive. If he suffers it to lie idle, when safe investments can be made, he will be charged with interest, and in some cases, as when he is guilty of gross delinquency, or if he misapplies the property with his own for his own benefit in trade or otherwise, he will be charged with compound interest. He will however be allowed a reasonable time without interest for making his investments, because he is bound to exercise due care in making them; and if he exercises this care, and especially if he follows the directions of a court or of statutes applicable to the case, he will not be liable for whatever loss may occur. He may not himself buy property which he sells as trustee, nor sell his own property and buy it as trustee; and this rule is applied not only to all trustees, but to agents generally.—An important difference between private and public trustees should be mentioned. Private trustees are responsible on the contracts they make as trustees, unless they guard against this by express reservation; and merely calling themselves trustees, or even saying they act as trustees, is not, generally speaking, sufficient. Thus an executor, signing a common promissory note as executor, is still liable on it personally, although the estate be insolvent. But public trustees, or persons acting in a known official capacity, are not personally liable on the contracts they make for the

state or government, unless they make themselves so expressly, or by a reasonable implication, or have in their hands funds for the purpose of the contracts. It is, of course, always in the power of one who deals with a public trustee or agent to ask of him his own personal liability; and it is always in the power of that trustee to give it or withhold it.

TRUXILLO, or **TRUJILLO** (anc. *Turris Julia*), a city of Spain, in Estremadura, province of Oaceres, situated on the Tozo, a tributary of the Tagus, 180 m. S. W. from Madrid; pop. 6,026. It consists of three parts, the citadel, old town, and city, which stand respectively on the summit, slope, and at the foot of a hill. The whole place has the appearance of decay, and the upper and more ancient part is now used as a burying ground, the inhabitants having abandoned it. The fortress dates from Roman times. In the lower town there is an extensive square, which contains among other large mansions one belonging to the family of Pizarro, the front being ornamented with numerous bas-reliefs representing the conquest of Peru. Francisco Pizarro was a native of this place, as were also many of the adventurers who assisted in the conquest of Peru. Roman antiquities have been discovered in the town and neighborhood.

TRUXILLO, or **TRUJILLO**, a town of Peru, capital of the department of Libertad, situated 1½ m. from the sea, in the valley of Chimu, lat. 8° 7' S., long. 79° 9' W.; pop. about 8,000. It is built upon the side of a mountain, and is surrounded by a mud wall flanked with bastions. There are some good brick houses, which are generally low. It is the see of a bishop, and has a cathedral and several large churches. There is a college, a hospital, and a theatre. Rice and spice are exported from Huanchao, which is the port of Truxillo, and lies about 8 m. N. W. from it. Truxillo was founded by Pizarro, who named it after his native town in Spain. In the neighborhood there are many ancient Peruvian remains.

TRUXTUN, **THOMAS**, an American naval officer, born on Long island, Feb. 15, 1755, died in Philadelphia, May 5, 1822. During the revolution he served in privateers and letters of marque as lieutenant and captain, was several times engaged, and made a number of valuable captures. In 1795 he received a commission as captain in the navy. His first service was in the frigate *Constellation*, of 38 guns. On Feb. 2, 1799, when off the island of Nevis, he fell in with, and captured after a close action of about one hour, the French frigate *L'Insurgente*, Capt. Barreault. The armament of *L'Insurgente* consisted of 40 guns with a complement of 409 men. She was much cut up, and lost 29 men killed and 40 wounded. The *Constellation* sustained but little injury, and had 8 men wounded. On Feb. 1, 1800, the *Constellation*, still commanded by Truxtun, fell in off Guadeloupe with the French frigate *La Vengeance* of 54 guns, Capt. Pitot. A long and severe encounter took place, in which both ships were

much crippled. La Vengeance escaped, and got into Curaçoa dismasted and in a sinking condition, with a loss of 50 killed and 110 wounded. The loss of the Constellation was 14 killed and 25 wounded. Her mainmast went by the board at the close of the action, which prevented her from pursuing her antagonist. For this action congress awarded Truxtun a gold medal. In 1801 he was transferred to the President, 44, in which ship he hoisted his broad pennant as commodore on the Guadeloupe station. At one time he had a squadron of 10 sail under his command. He resigned his commission in 1802, and afterward filled important civil offices.

TSCHIRNHAUSEN, EHRENFRIED WALTER von, count, a German mathematician and philosopher, born on his father's estate of Kislingswalde in Upper Lusatia, April 10, 1651, died there, Oct. 10, 1708. At 17 he entered the university of Leyden, and in 1672 volunteered in the Dutch army in the war against France. In 1673 he began a journey, in the course of which he visited England, France, and Italy. On returning he gave his attention to the construction of optical instruments, and established glass factories and a mill for the polishing of burning glasses, one of which, weighing 160 pounds and 33 inches in diameter, is now in the cabinet of the academy of sciences at Paris. He also constructed a burning mirror of highly polished copper 5 English feet in diameter, and the focal distance of which was 3.7 feet; it is now in Dresden. Several communications by him upon subjects of this character are to be found in the *Acta Eruditorum*. Tschirnhausen also discovered a method of making porcelain, from which the manufacture of porcelain in Saxony took its rise. In philosophy, he wrote *Medicina Mentis* (Amsterdam, 1687), a kind of companion work to *Medicina Corporis* published by him the year previous. In mathematics, he investigated the properties of the curved line which goes under his name.

TSCHUDI, an ancient and noble family of the canton of Glarus, Switzerland. The ancestor of the house was Johann, who was ennobled by the emperor Louis III. in 906; and from that time many of his descendants have been distinguished in the wars of the crusades, in the wars against Austria, and in the French service. The most celebrated members of the family are the following: I. ÆGIPIUS (GILLES), a Swiss historian, born in the canton of Glarus in 1505, died Feb. 28, 1572. One of his first instructors was the reformer Zwingli; afterward he studied at Basel, Paris, and Vienna. In 1528 he was made ambassador from the canton of Glarus to the assembly of the state which met at Einsiedeln to deliberate in regard to matters connected with the reformation; in 1529 became governor of Sargans; and in 1532 was chosen by the abbot of St. Gall as the manager of several estates belonging to the abbey. In 1538 he was made governor of Baden, and received the same position in 1549 after having been for 8 years in the French service. In 1556

he was stadtholder and in 1557 landammann in Glarus. In 1559 he was sent by the confederation to Augsburg to demand of the emperor Ferdinand I. the confirmation of their rights and privileges. Subsequently, when the strife between the Catholics and Protestants grew fiercer in the canton of Glarus, he strongly supported the side of the former, and in consequence drew upon himself to such an extent the aversion of his countrymen, that after 1563 he resided partly in Rapperschwil and partly in the convent of Einsiedeln; but in 1564 he returned to Glarus, where he spent the remainder of his life engaged in literary studies and political duties. He was one of the most learned and prolific writers of his time, though only a few of his works have been published. Beside a number of treatises known only by their titles, there are 166 of his works specified as existing either in print or in manuscript, the most celebrated being his chronicle of Swiss history to the year 1570, but which has been printed only as far as 1470 (3 vols., Basel, 1784). This work was written in German, and is regarded by the Swiss historian Johannes von Müller as an original authority. His life has been written by Fuchs, *Agid Tschudi's Leben und Schriften* (2 vols., St. Gall, 1805).

II. JOHANN JAKOB, a Swiss traveller, naturalist, and ethnologist, born in Glarus, July 25, 1818. He was educated at the gymnasium and the university of Zurich, and continued his studies in natural history in Neuchâtel, and afterward in Leyden, where he published his *System der Batrachier* (1838), and in Paris. From this last named city he set out, in Feb. 1838, on a voyage around the world; but as the vessel was sold to the Peruvian government on reaching that country, his investigations were limited to the study of the natural history and ethnology of Peru. In 1843 he returned to Europe, and, being prevented from taking part in the arctic expedition under command of Capt. Franklin, settled on his estate of Jacobihof near Wiener-Neustadt in Lower Austria. He has published *Peru: Reisen aus den Jahren 1838-42* (2 vols., St. Gall, 1846; translated into English in 1847 by T. Ross); *Untersuchungen über die Fauna Peruviana* (St. Gall, 1844-'7); and *Die Ketschwa-sprache* (2 vols., Vienna, 1853), which contains a grammar and dictionary of the Peruvian language. He has also edited, in conjunction with Don Mariano Eduardo de Rivera, the *Antigüedades Peruanas* (Vienna, 1851; translated by the Rev. F. L. Hawks, 8vo., New York, 1854).

III. FRIEDRICH, born in 1820, is the author of a celebrated work entitled *Das Thierleben der Alpenwelt* (Leipzig, 1852; 2d ed., 1854).—The history of the family has been written by Blumer under the title of *Das Geschlecht der Tschudi* (St. Gall, 1858).

TSETSE, the native name of a proboscidean dipterous insect of the genus *glossina* (Wiedemann), peculiar to Africa, and especially to the tropical portions. This genus comes near

tomoxys (Fabr.), and resembles in appearance and habits the gadfly called in Scotland *cleg* *hematopota pluvialis*, Meig.). The best known species, *G. morsitans* (Westw.), is 5 lines long and $8\frac{1}{2}$ in expanse of wings, a little larger than the house fly; the head is dirty buff, and the eyes large; thorax chestnut red, with 4 longitudinal black bars; abdomen dirty buff, with black bristles above, the first segment with a round black spot at each side, and the 4 following with a broad dark brown band interrupted in the middle; the wings are considerably longer than the body. The blood-sucking apparatus consists of a long horny proboscis, containing a compound bristle or 2 needle-like piercers, communicating with a poison bulb at the base, and supported on each side by 2 leathery palpi. It is very active and difficult to catch, except in the cool of the morning and evening, when it is sluggish; it has a loud and peculiar buzz, which does not terrify cattle like that of the gadflies. This scourge of the African wilderness has no sting in the tail, and deposits no eggs on or under the skin of animals, but introduces its poison into the blood by the proboscis during the act of sucking. The puncture of the tsetse is almost certain death to the ox, horse, sheep, and dog, but is harmless to man, the mule, ass, goat, pig, wild animals, and even calves while sucking; in man it causes a slight itching, like that after the bite of the mosquito or flea. It produces no immediate effect in the ox or horse, but in a few days there appears an exudation for half an inch around the punctures, the eyes and nose begin to run, the skin quivers as if from cold, and swellings occur under the jaw; the animal may continue to graze, but by degrees grows thin and weak; this state may continue for months, until purging comes on, and death ensues from exhaustion. The better the condition of the animal bitten, the more speedy often will the death be, accompanied by symptoms of staggering and blindness, as if the poison affected the brain; sudden changes of temperature hasten the progress of the disease, which, according to Dr. Livingstone, in spite of every care and medical treatment, goes on to certain death. They occasionally attack a horse like a swarm of bees, alighting on him by hundreds, sometimes causing death in a week. After death the subcutaneous areolar tissue is found injected with air, and the fat is oily and greenish yellow; the heart and muscles are very soft and flabby, the gall bladder distended with bile, the blood much reduced in quantity, with signs of disease in the lungs and liver. No remedy is known against the effects of their bite; the natives pretend to have roots which, pounded and sprinkled on the hair, prevent the bite, but their inability to keep cattle proves their inefficacy; the droppings of animals mixed with human milk and drugs, and smeared on the hide, often prove a temporary safeguard; an animal slightly bitten and escaping death will fall a victim to the next se-

vere bite. With the destruction of the game, this insect, deprived of its food, may become extinct; and until it does, whole districts are rendered unable to keep cattle, horses, sheep, or dogs. It is found chiefly in the bush or among reeds, and rarely in the open country; it is confined to limited regions, which it never leaves, so that cattle may graze in quiet on one side of a river while the opposite bank swarms with tsetse. If obliged to pass through a country infested by them, the natives select a moonlight winter night, when they are torpid from cold. The flesh of animals bitten by the tsetse is not unwholesome, if they are killed before emaciation and weakness supervene. According to Westwood ("Proceedings of the Zoological Society of London," No. 217, Dec. 1850), the tsetse is the same as the *zimb* of Bruce (a modern Arabic word), and the *zebub* in Hebrew; the marquis of Spineto ("London and Edinburgh Philosophical Magazine," 1884, vol. iv. p. 170) identifies the *zimb* with the *κυνόμυια* or dog-fly of the Greeks, with the *taal tsalya kelt* of the Alexandrian church, with the *af anhor* of the ancient Egyptians, with the *arob* of Exod. viii., the fly which caused the 4th of the plagues of Egypt, and with the *ostrus* of Aristotle (but not of the moderns). In the paper above cited Westwood describes two other new species, the *G. tachinoides*, smaller, and the *G. tabaniformis*, larger than the common species, both from western tropical Africa. Gordon Cumming alludes to, and O. J. Anderson and Dr. Livingstone give an extended account of the ravages of this insect.

TSUS-SIMA, an island of the Japanese empire, lying in the strait of Corea, S. W. of Nippon, in lat. 34° N., long. 129° E. It is 35 m. long and 10 or 12 broad, and is separated by a narrow strait from the island of Fatchin, lying S. W. of it. A chain of high and rugged hills, with deep but fertile valleys, extends through nearly the whole length of the island. It is now an important naval depot of the Russians, who took possession of it in June, 1861, after a bombardment in which a considerable loss was suffered on both sides.

TUAM, a town of Connaught, in the county of Galway, Ireland, on both sides of the Harrow, 19 m. N. N. E. from Galway; pop. in 1851, 7,819. It contains both Protestant and Roman Catholic cathedrals, the Roman Catholic college of St. Jarlath, several public schools, a monastery, and a nunnery. The workhouse and other public institutions in 1851 contained 2,881 inmates. The manufactures are trifling, but there is a considerable trade in grain. Tuam is a place of great antiquity, and had a cathedral founded by St. Jarlath in the 6th century. It is the see of a Roman Catholic archbishop, and was an archiepiscopal see of the established church from the 12th century to 1839, when it was reduced to a bishopric, with Killaloe and Achonry, suffragan to Armagh.

TUARIKS, or TOUTARENS, a people supposed to be of the Berber or Amazirgh race, occupy-

ing that portion of the great desert of Sahara lying between Morocco and Soodan, and extending westward from Fezzan to the Atlantic. They assert that they came originally from Canaan, and may be the descendants of some of the tribes driven out by the Israelites. They are Caucasian in their features, and, though of dark complexion, have straight hair, and bear no resemblance to any of the negro races. They are tall and handsome, bold, warlike, and predatory, and live chiefly on booty and tribute exacted from their neighbors. They are very zealous Mohammedans, and are governed by independent chiefs. (See *AZKAR TUARIK*.) The Tibboos, who occupy that portion of the desert lying between Fezzan and Egypt, are considered a branch of the same family with the Tuarika. Baron Aucapitaine (*Nouvelles annales des voyages*, Dec. 1861) estimates the total number of the Tuarika at 192,000.

TUBEROLE. See CONSUMPTION.

TUBEROULAR MENINGITIS. See HYDROCEPHALUS.

TUBEROSE, a fragrant flower of the liliaceous order, called by botanists *polyanthes tuberosa*, blossoming in the autumn. Its native country is unknown; it was first noticed in Europe by Clusius, a Dutch writer of the 16th century, who received it as an Indian plant. The old gardeners designated it as the Indian hyacinth and the *plante tubéreuse*. It is an endogenous perennial, with a thick, fleshy, tuberous root, from the crown of which issues a slender stem about 3 feet high, bearing numerous long, linear lanceolate leaves, and at the summit a spike of conspicuous white flowers, the corolla being monopetalous and funnel-shaped, the tube incurved, the rim outspread and divided into 6 segments, the seed vessel an obtuse, roundish, 8-cornered, 8-celled capsule, filled with half-round seeds arranged in a double row. There are several varieties; the one with double flowers is the most esteemed. The slender tuberose (*P. gracilis*), a native of Brazil, was brought into notice in 1822; its flowers are of a pale yellow, but it is otherwise like the common kind.—The tuberose is usually imported into the United States with flower bulbs from Holland, and the largest and firmest roots, deprived of their offsets, are selected for blooming. They should be potted early in the spring in light sandy soil, and brought forward in frames, planting them out in the flower border in May or June. When the flowers are ready to expand, they are carefully lifted with balls of earth adhering to the roots and repotted. If early shifted into large pots, these may be sunk in some warm border, the stems being tied to stakes, and the pots being lifted on the approach of cold weather.

TÜBINGEN, a walled town of Württemberg, circle of Schwarzwald, situated on the left bank of the Neckar at its junction with the Ammer, 18 m. S. by W. from Stuttgart, and 69 m. E. from Strasbourg; pop. about 10,000. It is noted for its university, founded in 1477, which

has a library of 200,000 volumes, and is attended by about 650 students.

TUCKER, ABRAHAM, an English metaphysician, born in London, Sept. 2, 1705, died in 1774. He was educated at Merton college, Oxford, and entered the Inner Temple, but was never called to the bar. In 1737 he purchased Batchworth castle, near Dorking, with a large estate belonging to it, and there devoted himself to the study of agriculture. In 1755 he published a pamphlet against strong political feeling, entitled "The Country Gentleman's Advice to his Son on the subject of Party Clubs." About this time he began his great work, "The Light of Nature Pursued, by Edward Search," 4 volumes of which were published in 1765; but a part of it had already appeared in 1763 under the title of "Free Will." A criticism on the work in the "Monthly Review" elicited from him a reply entitled "Man in Quest of Himself, by Cuthbert Comment." He became blind in 1771, but continued to work upon his "Light of Nature Pursued" until the close of his life, the remaining volumes of which were edited by his daughter, after his death. The best edition of his work is that of Sir Henry Mildmay (7 vols. 8vo.; reprinted in 1837 in 2 vols. 8vo.).

TUCKER, HENRY ST. GEORGE, an American jurist, born in Virginia in 1779, died in Winchester, Va., Aug. 28, 1848. He received a liberal education, devoted himself to the legal profession, and became president of the court of appeals and professor of law in the university of Virginia. From 1815 to 1819 he served as a member of the lower house of congress. Among his legal works, which gave him a high reputation, are: "Lectures on Constitutional Law," "Commentaries on the Laws of Virginia" (2 vols. 8vo., Winchester, 1836); and "Lectures on Natural Law and Government."

TUCKER, JOSIAH, a British divine and political writer, born in Langhorne, Caermarthenshire, in 1711, died in Gloucester, Nov. 4, 1799. He was educated at St. John's college, Oxford, took orders, and in 1749 was presented to the rectory of St. Stephen's, Bristol. In 1758 he was made dean of Gloucester. He published a number of treatises relating to political economy, the earliest of which was entitled "A Brief Essay upon the Advantages and Disadvantages which respectively attend France and Great Britain with regard to Trade" (1748). His pamphlet entitled "The Case of going to War for the sake of Trade, considered in a new Light" (1763), was translated into French by Turgot. His most remarkable publication was "Reflections on the Present Matters in Dispute between Great Britain and Ireland" (1785). He also began a work on the "Elements of Commerce and Theory of Taxes," which he did not finish. For his support of the bill allowing Jews to be naturalized he was burned in effigy by the people of Bristol. At the time of the American revolutionary war he strenuously resisted the claims of the colonies, but at the same time opposed coercion, as

is believed that the possession of colonies was detrimental to the interests of a country. In the controversies upon this war he came into collision with Burke, who in his speech on American taxation, in April, 1774, treated him with no great respect. In theology he wrote in "Apology for the present Church of England," "Letters to Dr. Kippis," and "Religious intolerance no part of the General Plan either of the Mosaic or Christian Dispensation." He likewise published "Seventeen Sermons on some of the most important Points of Natural and Revealed Religion." His works have never been collected.

TUCKER, ST. GEORGE, an American poet and jurist, born in the island of Bermuda, June 29, 1752, died in Nelson co., Va., in Nov. 1827. He was educated at the college of William and Mary, and studied law, but on the breaking out of the revolutionary war took up arms, and planned and aided personally in a dangerous but unsuccessful attempt to capture a large amount of stores in a fortification at Bermuda. In 1778 he was married to Mrs. Randolph, the mother of John Randolph of Roanoke. At the siege of Yorktown he was present in the capacity of a lieutenant-colonel. After the conclusion of the war he was elected a member of the general court, and while holding this position was also law professor in William and Mary college; and he was one of the commissioners to the convention which in 1788 met at Annapolis, Md., and recommended the convention by which the present constitution of the United States was formed. In 1803 he was appointed judge of the court of appeals, and subsequently in the district court of the United States. He was the author of a large number of minor poems, one of which, entitled "Days of my Youth," has retained its popularity; and he published an essay on the question "How far the Common Law of England is the Common Law of the United States;" a treatise on "Slavery" (1796); a letter on the "Alien and Sedition Laws" (1799); and an annotated edition of Blackstone's "Commentaries." His poetical works, which have never been collected, would fill several volumes.—BEVERLY, an American lawyer and novelist, son of the preceding, born in Macon, Va., Sept. 6, 1784, died in Winchester, Va., Aug. 26, 1851. He was educated at William and Mary college, studied law, and in 1809 settled in Charlotte co., and in 1815 in Missouri, where he became a judge. In 1834 he became professor of law in William and Mary college, and held that position until his death. He published a work on "Pleading," lectures on the constitution of the United States under the title of "The Science of Government," and novels entitled "George Balcombe" and "Gertrude;" but his most remarkable production was an unfinished novel called "The Partisan Leader," first printed in 1837, and reprinted in 1861. The scene is laid in Virginia in 1849, 12 years after its first publication, and Mr. Van Buren, the head of a republic in name, but of a

monarchy in reality, is represented in his third presidential term. At the time of its republication it attracted great attention, as showing how long the project of a secession of the southern states had been entertained, and for the accuracy with which it foretold much that had since happened. Beverly Tucker was also a contributor to the "Southern Review," and had begun shortly before his death a life of John Randolph, his half brother.

TUCKERMAN, HENRY THEODORE, an American author, born in Boston, April 20, 1818. He received his education in Boston and its vicinity, and in 1838, when about to enter college, was induced by the state of his health to visit Europe. Having passed a winter in Italy, he returned to America in the summer of 1834, and 3 years later revisited Europe, and passed nearly 2 years in Sicily and Florence. In 1845 he removed from Boston to New York, where he has since resided, except during the summer months, which he passes chiefly in Newport, R. I. In 1850 he received from Harvard university the honorary degree of A.M. In 1835 appeared his first publication, "The Italian Sketch Book," a collection of descriptive and historical sketches, essays, and tales; and since that time he has occupied himself exclusively with literary pursuits, having been a regular and frequent contributor to the "North American Review," the "Christian Examiner," the "Democratic Review," "Graham's Magazine," the "Southern Literary Messenger," "Putnam's Monthly," the "Atlantic Monthly," and other periodicals, in the pages of which the essays, æsthetic, biographical, and critical, which form the bulk of his works, were originally published. His next work in the order of publication was "Sicily, a Pilgrimage" (1839), in which the author's experience is described under the guise of fiction. It was followed by "Rambles and Reveries" (1841); "Thoughts on the Poets" (1846), devoted chiefly to masters of the English school (translated into German by Müller); "Artist Life, or Sketches of American Painters" (1847); "Characteristics of Literature" (1849), of which a 2d series appeared in 1851; "The Optimist" (1850), a collection of miscellaneous essays; a "Life of Commodore Silas Talbot" (1851); "A Month in England" (1853), the fruits of a brief visit to Europe in 1852; "Memorial of Horatio Greenough" (1853); "Leaves from the Diary of a Dreamer" (1853); "Biographical Essays" (1857). In 1851 a collection of his poems, embracing an elaborate metrical essay entitled "The Spirit of Poetry," was published in Boston. Among his incidental writings may be mentioned a comprehensive "Sketch of American Literature," appended to Shaw's "Outlines of English Literature."

TUCKERMAN, JOSEPH, D.D., an American clergyman, born in Boston, Jan. 18, 1778, died in Havana, Cuba, April 20, 1840. He was graduated at Harvard college in 1798, and in 1801 was settled as pastor of a Unitarian

society in Chelsea, near Boston, where he remained for 25 years. He became greatly interested in improving the condition of seamen, who composed a large portion of his parishioners, and in 1812 was instrumental in the formation of the first charitable society for their benefit in the United States; and he wrote and published several tracts for seamen in connection with this society, which eventually led to the formation of the American seamen's friend society and other institutions for sailors. In 1826 he resigned his pastorate and commenced laboring as a missionary among the poor in Boston, at first at his own expense; and at the end of 18 months he had brought 250 families under his supervision and instruction, providing for most of them food, raiment, and occupation, as well as religious instruction. Others were stimulated by his efforts to undertake the same work. In 1830 he wrote an essay "On the Wages paid to Females," which received a prize offered in Philadelphia. His labors and articles in the religious periodicals led to the organization of the "Benevolent Fraternity of Churches" for the support of a city mission, called the "Ministry at Large," and Dr. Tuckerman became one of its ministers; in 1831 his reports to it were published in a 12mo. volume (3d ed., 1832). While on a visit to Europe in consequence of his impaired health, he promoted the organization of similar institutions for the poor in several cities of Great Britain. On his return he resumed his labors, and published "Principles and Results of the Ministry at Large;" but his health again failing, he sailed for Cuba, where he died. His remains were interred at Mount Auburn, where a fine monument has been erected to his memory.

TUOUMAN, a province of the Argentine Confederation, bounded N. by Salta, E. by Gran Chaco, and S. and W. by Santiago and Oatamarca; area, 37,000 sq. m.; pop. about 50,000. In the W. the surface is traversed by several offsets from the Andes, but in other directions there are extensive plains. The most important rivers are the Salado, Tala, and Medinas. There are several shallow saline lakes, and in many places extensive tracts covered with fossil salt. The water of nearly all the streams is brackish. The climate of the plains is hot. The soil affords good crops of grain and fruits, and excellent pasturage. The exports consist chiefly of cattle and timber, the latter of which is sent to Buenos Ayres and also to Potosi. Capital, Tucuman, or San Miguel de Tucuman.

TUDOR. See HENRY VII.

TUDOR, WILLIAM, an American author, born in Boston, Jan. 28, 1779, died in Rio Janeiro, March 9, 1830. He was educated at Phillips academy, Andover, and at Harvard college, where he was graduated in 1796, and entered the counting room of John Codman, in whose employ he visited Paris. He afterward made a tour to Italy and the continent, and on his return engaged in founding the "Anthol-

ogy Club," and contributed various articles to its journal, the "Monthly Anthology." In 1815 the first number of the "North American Review" appeared under his editorship, and three fourths of the first 4 volumes were written by him. In 1819 he published a volume entitled "Letters on the Eastern States;" in 1821 a volume of "Miscellanies;" and in 1823 a "Life of James Otis." In 1823 he was appointed U. S. consul at Lima, and in 1828 was made chargé d'affaires at Rio Janeiro, where he wrote a work published anonymously under the title "Gebel Teir" (Boston, 1829). He was one of the founders of the Boston Athenaeum, and it is to him that the country is indebted for the first suggestion of Bunker Hill monument.

TUESDAY, the third day of the week. In the Roman calendar it was called *dies Martis*, from Mars, and its present name is derived from Tiw, the Anglo-Saxon god of war.

TUFA. See CALCAREOUS SPRINGS.

TUFTS COLLEGE. See MEDFORD.

TUL. See POZ BIRD.

TUILERIES (Fr. *tuile*, a tile), a royal palace with extensive gardens in Paris, lying between the Seine and the rue Rivoli, and E. of the Place de la Concorde, so named because it occupies the site of a former manufactory of tiles. The present building was commenced in 1564 by Catharine de' Medici, wife of Henry II., according to the plans of Philibert Delorme and Jean Bullant, who built the central pavilion, called the *pavillon de l'horloge*, the two adjoining wings, and the pavilions by which they are terminated. Henry IV. added a range of buildings ornamented with large composite pilasters and a lofty pavilion at each end of the original structure, the whole presenting a façade 336 yards in length by 36 in depth, running at right angles with the river, and in a direction nearly N. and S. The same monarch also commenced the gallery fronting the Seine which connects the S. extremity of the building with the Louvre, and which was finished by Louis XIII. and Louis XIV. The latter harmonized the architecture of the whole building, replacing the spherical dome of the *pavillon de l'horloge* by a quadrangular one; and in 1808 Napoleon I. commenced a northern gallery along the rue Rivoli, parallel to that already constructed. This was completed by Napoleon III., and the Tuileries and the Louvre now form one great connected pile, enclosing the Place du Carrousel, which is separated from the court of the original palace of the Tuileries by an iron railing. The front of the building, in spite of glaring architectural incongruities, is exceedingly imposing, and the interior unsurpassed in magnificence by any royal residence in Europe. The gardens of the Tuileries, lying west of the palace and extending to the Place de la Concorde, embrace a quadrangular area of nearly 50 acres, and are among the most attractive public resorts in Paris.—After the completion of the palace of Versailles no French king lived in the Tuileries

until 1789, when Louis XVI. found himself compelled to remove thither from Versailles. On Aug. 10, 1793, the Parisian populace stormed the building and massacred the Swiss body guard of the king. It subsequently became the residence of Napoleon during the consulate and the empire, and of the Bourbons after the restoration. During the revolution of July, 1830, it was again taken by the people; and at the expulsion of Louis Philippe in Feb. 1848, it was for the third time ransacked. It is now the imperial residence of Napoleon III., who is (1869) rebuilding the *pavillon de Flore* on the front corner next the river.

TUISCOO, THUISCOO, or TEUT (Anglo-Saxon, Tiw), the god whom the ancient Germans revered as the earth-born founder of their nation. He was represented as a gray-bearded man, with uncovered head clad in the skin of an animal, holding a sceptre in his right hand, and stretching out the left. His son Mannus (man), by Hertha (earth), was the first of the Teutones (*Teutsche, Deutsche, Germans*), and the father of the progenitors of their three principal tribes. Both Tuisco and his son gave laws to their nation, and the name of the day on which the early Germans held judicial meetings, Tuesday, is derived from that of the former.

TULA. See TOOLA.

TULARE, a S. E. co. of California, bounded S. W. by the Coast range, and N. E. by New Mexico, and drained by Owen's and Kern rivers and other streams; area over 12,000 sq. m.; pop. in 1860, 4,688. The Sierra Nevada mountains traverse the central part of the county. The agricultural productions are of small amount. Gold is abundant, and in 1858 there were 9 quartz mills; placer mining is also pursued. Tule lake, over 80 m. long and about 20 m. wide, is in this county. Capital, Visalia.

TULIP (Persian, *thoulyban*, turban), the name of a superb garden flower of the natural order of the *liliaceae*, known for its great number of sorts, all derived from a single species, the *tulipa Gemeriana*, a native of the Levant. The tulip has a bulbous root, from the apex of which issue a few broad, glaucous, herbaceous leaves, surrounding at base a simple stem (scape), which usually supports a single flower composed of a perianth of 6 colored petals, within which is a row of 6 subulate stamens, which are not so long as the petals, surrounding a 3-angled, 3-celled ovary, whose stigma is sessile, 8-lobed, triangular, persistent; the fruit is a capsule filled with many smooth flattened seeds. The garden tulip appears to have been cultivated for a long period among the Turks; it was introduced into western Europe in 1554, and first described by Conrad Gesner shortly afterward. Its ripe seeds were regularly imported into Holland from Constantinople, and that country soon became distinguished for its trade in bulbs. In Great Britain it is assiduously nurtured, and superb sorts have originated there among gardeners and amateur florists from continued culture and from the sowing

of its seeds, a process which is long and tedious, from 5 to 20 years being required to ascertain the possible qualities of the seedling plants. The finest varieties of the plant amount to several hundred, each bearing some distinctive trivial name; the specific differences between them consist in the manner in which the colors are distributed upon the petals. Thus, such tulips as have certain general and predominant colors are divided into 4 sections, each of which comprises very many sub-varieties. When the yellow ground of the flower is marked with purple or scarlet of different shades, it is called *bizarre*; when its white ground is marked, lined, striped, or variegated with violet or purple only, of various shades, the tulip is called *byblamen*; such as are variegated with scarlet, crimson, cherry color, or rose are called rose tulips; and those which have a white or yellow ground without any marks are termed selfs or plain-colored. When those colors occur in a broad central stripe in any of the flowers of the 8 first kinds, the tulip is said to be flamed; and when they are arranged on the petals in delicate pencillings, the tulip is feathered, this style being very beautiful. The selfs have but a single color, yet by changing the character of the soil or by other processes they may become variegated, and these tulips are called "breeders," because employed to breed or propagate the choicest kinds. The development of these variegated colors is termed the breaking of the tulip, and it is not unusual that several years are requisite to produce the desired effect. The precise *rationale* of this result does not seem to be well ascertained, but it is perhaps only the continuous effort of nature to produce the normal condition of striped flowers, the self color being only primitive and transitional. A good tulip flower must not only be well colored and pencilled, but its form must be perfect. Thus the properties of a good tulip consist in its being from one third to one half of a hollow globe, the edge smooth and even, the petals thick, and the marking of colors unbroken round the exposed edges of the petals when expanded, but this edging must not extend more than half way down the petal; all the 6 petals must be precisely alike, the colors well defined, the base of the petals free from the slightest stain, and the flower stem straight and stiff, from 18 to 36 inches high. The garden tulip loves a rich loam, and when its best effects are to be studied, the different sorts are selected with reference to this, and are planted in long narrow beds so that they can be readily inspected when in full bloom, or can be protected by awnings from the sun and rain. The beds should be in some open, airy situation, free from the shade of trees or of houses, and all surplus moisture should be carried off from their surface. The usual width of a bed is 4 feet, and one 21 feet long will contain 280 bulbs placed 6 inches from the edge and 6 inches apart each way. It is usual to plant duplicate roots, as some may

not blossom; and even if all should do so, still the effect will be better. A bed of 100 rows and 700 bulbs or roots, containing 400 varieties judiciously selected and well arranged, will produce a very brilliant display. Such beds in preparation should be furnished with 20 inches depth of compost soil, consisting of two parts of fresh, rich, rather sandy loam, and one part of well rotted cow dung. The time for setting the bulbs is about the middle of September, when they are to be planted 5 inches below the surface. In the United States a slight covering of boughs, leaves, or sea weed will be found to be sufficient protection in winter, removing it in the spring when the plants push themselves above the surface. During their growth all weeds are to be carefully pulled up and the beds kept clean and tidy. After blooming and on the fall of the petals the seed vessels should be broken off in order to prevent the bulb from becoming weak through the effort to ripen the seeds; and when the foliage has turned brown and dry, the bulbs are to be carefully lifted out, dried, and cleaned, and put away for replanting. The tulip will bloom very well for several years, however, without any such extra care; but when the blossoming is feeble, indicating a too crowded state of the roots, they should be transplanted at the proper season.—There are some early sorts of tulips much prized in gardens, known in the flower catalogues as the Van Thol and sub-varieties of the sweet-scented tulip (*T. suaveolens*, Willd.). These are all dwarf, the stem leaves ovate-lanceolate in outline, the scape low, bearing an erect flower, the petals of which are a rich scarlet edged with yellow. Their humble habit renders them fit to mingle with crocuses on the edges of hyacinth beds, or to force in pots or water glasses for flowering in January or February. The double flowers of this species, as well as the double-flowering varieties of the common garden tulip, are in less esteem than the single flowers, though curious objects; but even oddly formed flowers of certain single sorts are well known, such as those called parrot from their particolored tints of green, yellow, and red, and their large, coarse, twisted, and undulate petals.—There are several other distinct species of the genus *tulipa* known, but they are seldom seen unless in botanic gardens; such as the wild tulip (*T. sylvestris*, Willd.), with narrow leaves, a somewhat drooping stem bearing a solitary yellow flower, the petals ovate-acuminate, hairy at their extremities, and the stamens hairy at the base; the small yellow tulip (*T. Celsiana*, Persoon), with a solitary, erect, greenish yellow flower with lanceolate petals, growing wild on the banks of the Volga; the 2-flowered yellow tulip (*T. biflora*, Pallas), found on the salt deserts in company with the last and not half its size, its flowers fragrant; the Italian tulip (*T. Clusiana*, Redouté), with red and white flowers of lanceolate petals; the many-flowered tulip (*T. Breyneiana*), with small reddish yellow blossoms, indigenous

to the Cape of Good Hope; and even in Siberia occurs a species (*T. Biebersteiniana*), with yellow and purple flowers appearing in June and July.—The commercial value of tulips at the present time is regulated like that of other commodities; and collections of very superior sorts may be procured for reasonable sums of money. The extraordinary traffic in them two centuries since in Holland, known as the tulipomania, was rather a gambling speculation than any actual transfer of the variety bargained for; and sometimes no individual root of the particular kind was in existence.

TULIP TREE (*Liriodendron tulipifera*, Linn.), the name of a genus of North American trees containing a single species, and belonging to the natural order of *magnoliaceae*. They are exogens with distinct carpels, usually large involute stipules, and imbricated corollas. The tulip tree is tall and stately, its trunk large and columnar, its head open and spreading, its limbs stretching strongly upward, and its branches proceeding outward at all angles. The bark of the trunk is of a dark ashen color, and is somewhat smooth, that of the young shoot brown or chestnut color, smooth with a grayish bloom and with narrow dots. The leaf bud is formed by 2 stipules cohering at their edges to form a sort of sheath, within which a minute leaf is seen folded together and bent down. By this arrangement, as each leaf expands, it is protected by the stipule until fully grown. The leaves are 4-lobed, each lobe ending in round or else sharp points, and separated by shallow broad sinuses, the terminal lobe ending abruptly as if cut off. Their color is a light green above and whitish or glaucous beneath, and their surface is smooth. Some variety exists in the acuteness or bluntness of these lobes. The flowers are large, solitary, and speciosa, the flower bud enclosed in a 2-triangular-leaved sheath, which falls on the expansion of the flower. The sepals consist of 8 concave, subcoriaceous, greenish, striated, spreading divisions, which are at length bent backward; the corolla of 6 fleshy, greenish yellow and dotted petals, striped and marked at base by a crescent-shaped orange spot; the pistil is large and of a conical shape, surrounded by numerous stamens with long anthers. Some varieties are known in gardens, distinguished by the shape of the foliage or the color of the flowers.—The tulip tree extends from New England along the Atlantic coast to Florida. It is also found abundantly in Upper Canada, and in the western states, where it attains its largest size, 120 to 140 feet high. Its beauty even when young renders it valuable for artificial planting in pleasure grounds or on highways and on the sides of streets. It propagates readily from seeds and layers, and by budding and grafting. Its seeds should be sown in the autumn in a fine mould and in cool and shady spots. The timber of the tulip tree is much prized as a substitute for pine where that is not found, and for panel work in coach building. The bark of its roots and branches possesses a bitter

pungent, aromatic taste, and aromatic odor, and can be made to act as a stimulating tonic, diaphoretic, and sudorific. According to Bigelow, it can be successfully employed in the treatment of chronic rheumatism and intermittent fevers.

TULL, JETHRO, an English agriculturist, born about 1680, died in Jan. 1740. He owned an estate near Hungerford, on the borders of Oxfordshire and Berkshire, and observing the advantage of cultivation of plants in rows, and of stirring and pulverizing the soil between them, he introduced this system of cultivating the soil. Encouraged by his success, he was led to adopt the erroneous principle that manure was not needed, as finely pulverized earth and moisture were sufficient for the growth of plants. This in the end ruined him, and brought discredit upon his system for a long time. He published a treatise on his new mode of cultivation (1781), and detached essays, which in 1751 were collected in one volume. See *AGRICULTURE*, vol. i. p. 280.)

TULLIUS, SERVIVS. See *SERVIVS TULLIVS*.

TULLOCH, JOHN, a Scottish clergyman, born at Tibbenuir, Perthshire, in 1822. He was educated at the university of St. Andrew's, and in 1844 was ordained a minister of the church of Scotland, having previously been licensed as a preacher and presented with a charge in the town of Dundee. Afterward he visited Germany, and studied the speculative theology of that country. In 1849 he removed to the parish of Kettins in Forfarshire, and in 1854 was appointed principal of St. Mary's college in the university of St. Andrew's. He has been a contributor to the "British Quarterly" and "North British Review;" in 1855 received the second of the Burnett prizes on the "Being and Attributes of God," amounting to £600; in 1859 published "Leaders of the Reformation;" in 1861, "English Puritanism and its Leaders;" and in 1862, "Beginning Life—Chapters for Young Men."

TULLUS HOSTILIUS, the third king of Rome, reigned from 673 to 641 B. C. The most memorable event of his reign is the war with Alba, celebrated by the single combat between the Horatii and the Curiatii, and the consequent acknowledgment of Roman supremacy. In the war against Fidena, an Alban army was led to the assistance of Rome by Mettus Fuffetius, the Alban dictator, who intended to go over to the enemy at the critical moment. Tullus discovered the treachery, had the traitor torn in pieces from chariot wheels, razed Alba to the ground, and transferred the inhabitants to Rome, where the great mass of them became the Roman *plebs*. After these successes Rome was afflicted with a pestilence, preceded by awful prodigies, and the king himself was seized with the disease. To propitiate the gods, he consulted the *Commentarii* of Numa; and having found the formula with which Numa had sacrificed to Jupiter Elicius, he attempted to call down the god, but fell into an

error in the use of the formula, and the god in his anger destroyed the king and his household by lightning. The account of Tullus Hostilius cannot be regarded as historical. He was probably the founder of the third patrician tribe, the Luceres.

TULLY, WILLIAM, an American physician and botanist, born in Saybrook, Conn., Nov. 18, 1785, died in Springfield, Mass., Feb. 28, 1859. He was graduated at Yale college in 1806, studied medicine at Philadelphia, and in 1808 settled in practice at Milford, Conn. He removed about 1815 to Upper Middletown, now Cromwell, Conn., where he became the intimate friend of Dr. Thomas Miner, whose views in relation to the nature and treatment of spotted fever (see *MINER, THOMAS*, and *SPOTTED FEVER*) he adopted and practised; and in 1819 or 1820 he established himself at Middletown. In 1822 he published with Dr. Miner the essays known as "Miner and Tully on Fever." In 1824 he removed to East Hartford, Conn., and soon afterward was elected president and professor of materia medica in the medical institution at Castleton, Vt. In 1827 he removed first to Albany, and afterward to Castleton, for greater convenience in delivering his lectures. In 1829 the trustees of the medical college vacated all the professorships and suspended the school for 8 years. He was professor of materia medica in the medical institution of Yale college from 1830 to 1841, when he resigned on account of disagreements on medical subjects with the other professors, which gave rise to a violent controversy. In 1851 he removed to Springfield, Mass. He passed his latter years in poverty, occupied with the preparation of his work on materia medica (4 vols. 8vo., Springfield, 1857-'60).

TUMBREL. See *CUCKING STOOL*.

TUMOR (Lat. *tumor*, to swell), a morbid swelling on any part of the body, not caused by inflammation. The classification of tumors has long tasked the ingenuity of surgical pathologists; but lately microscopic investigation has furnished the basis of a new arrangement of them, which, if not scientifically correct, has the advantage of practical utility. They are divided into tumors whose histological elements are similar to those which exist in the normal textures, and tumors whose elements differ histologically from those found in the normal body. The first are termed homologous tumors, and are benign or non-malignant; of themselves they exercise no very deleterious influence, but they may be productive of serious inconvenience by their bulk, or of death by their pressure on important organs; while, as a result of mechanical injury or irritation, they are subject to inflammation and ulceration. The second class of tumors, whose elements form no part of the normal tissues, are termed heterologous or heteromorphous; they are malignant, having a tendency to convert the surrounding tissues into structures resembling their own, are attended with a constitutional

cachexia, and independent of extrinsic causes have a tendency to softening and ulceration. Homologous or non-malignant tumors again are variously subdivided. Under the head of sarcomatous tumors are classed: 1, tumors consisting of hypertrophies or excessive growths of certain glandular structures, as of the mammae, the thyroid gland, the testicle, &c.; and 2, tumors whose structure approximates to that of the ordinary areolar tissue. Fibrous tumors are formed exclusively of fibrous tissue; occasionally, when they are large and of long standing, calcareous salts are deposited within them, and sometimes cysts containing fluid are met with in their substance. They are commonly movable and enclosed in a cyst formed from condensed cellular tissue. Polypi of the uterus, the nose, and the ear are usually fibrous tumors. Neuroma is a form of fibrous tumor which occurs in connection with the spinal nerves. "It is remarkable," says Rokitsansky, "that neuroma is never deposited in the centre of a nerve, but at its side, so that only a small part of its fasciculi is displaced; the displaced fasciculi are spread abroad and stretched over the tumor, while the greater mass of the nerve remains on the other side uninjured, and with its fibres in connection with one another." Fatty tumors are characterized by their name; they are formed of fat cells more or less intermixed with areolar tissue. The term encysted tumor is confined to tumors in which no organized connection exists between the cyst and its contents. Sometimes there is a single cyst, and sometimes there are numerous cysts connected together. The contents of the cysts vary greatly in character and consistence; they may be watery or glairy, of the consistence of honey (meliceritious), of pap (atheromatous), or of lard (steatomatous). They vary greatly in color; occasionally they may contain hair, teeth, or bony matter. Cartilaginous tumors (*enchondroma*) may occur in glandular organs, the breast, parotid gland, &c., and in the interior of bones, or more commonly in their outer surface; they may become ossified, or may undergo soft or fatty degeneration. Finally, true osseous tumors are met with; they are almost invariably developed on and within bone, and may be soft or cancellar in their texture, or compact and of an ivory-like hardness, and sometimes attain an enormous size.—Heterologous or malignant tumors include all the varieties of cancer. Tubercle seems to form a connecting link between homologous and heterologous tumors.

TUMULUS. See BARROW.

TUNBRIDGE WELLS, a market town of Kent, England, situated in a beautiful country, 15 m. S. W. from Maidstone; pop. in 1851, 10,587. It is a fashionable watering place, and consists chiefly of clusters of houses standing on detached eminences, and of a parade lined with fine trees on one side, and on the other with assembly rooms, libraries, and shops. The surrounding country abounds in mineral

springs. The one to which the place owes its origin is a light pure chalybeate, and the water is considered remarkably efficacious in cases of weak digestion.

TUNGSTEN (Swed. *tung*, heavy, and *sten*, stone), a metal existing in the form of an acid combined with lime in the mineral scheelite or tungstate of lime, and also combined with iron and manganese in the mineral wolfram. Tungstic acid was discovered by Scheele in 1781, and metallic tungsten somewhat later by the brothers D'Elhuyart. Its German name *Wolframium* gives to it the symbol W, by which it is known in chemistry. It is obtained as a heavy iron-gray metal, very hard and difficult of fusion, and of the high specific gravity 17.4, by intensely heating tungstic acid made into a paste with oil, in a crucible lined with charcoal, for some hours. The tungstic acid is procured by decomposing the tungstate of lime with hydrochloric acid, which dissolves the lime and leaves the tungstic acid. The chemical equivalent of tungsten is 92.—Tungsten combines with several other metals, forming alloys of interest. Its combination with cast iron is remarkable for its extraordinary hardness; and it is said that cast steel containing 45 per cent. of tungsten is greatly improved in tenacity, hardness, and susceptibility of taking a fine temper. According to experiments made at the polytechnic institute at Vienna, steel of this kind exceeded all others in ability to resist compression. It is prepared by the use of the mineral wolfram, which is first purified by roasting, pulverizing, and washing, lastly with dilute hydrochloric acid; it is then mixed with coal dust and heated to redness in a crucible for 8 hours. The gray porous mass thus obtained, consisting of metallic tungsten and carburets of iron and manganese, is thrown into the crucibles in which cast steel is melted. Before casting the steel the heat of the fire is increased for 10 or 20 minutes. The objection to the use of tungsten for this purpose is the difficulty attending all new methods of manufacturing steel, viz., that of producing an article in large masses of uniform quality.—Of the two oxides of tungsten, W_2O_5 and WO_3 , the latter only, or tungstic acid, is of particular interest. This occurs native in bright yellow cubes, also as an earthy substance like ochre at a few localities, as at Lane's mine, Munroe, Conn. Cabarrus co., N. C., &c. But the usual form of the acid is in the combinations already named, and of these wolfram ($MnO, WO_3 + 3FeO, WO_3$) is the most common ore of the metal. This is a brownish black mineral, of metallic lustre, of hardness 5 to 5.5, and specific gravity 7.1 to 7.55. It is often found associated with tin ore in Cornwall, Saxony, Bohemia, and France. In the United States it has been found at Munroe, Conn., with native bismuth, galena, blende, &c., also at Trumbull in the same state, and near Mine La Motte, Mo., and Blue Hill bay, Me. Its detrimental effects to the ores of tin have already been noticed in treating that

metal. By the chemical method adopted of separating the tungsten ores from the tin ores, tungstate of soda is obtained, which is easily dissolved, and is found of value as a mordant in calico printing, and possesses the important property of rendering fabrics unflammable. See INCOMBUSTIBLE CLOTH.) Tungstic acid is also found in combination with lead, forming the mineral scheelite, and also with copper, and it occurs in small quantity in the mineral titanite. The artificial tungstate of lead produces a pigment resembling white lead. The following are some of the attempted applications of the compounds of tungsten to economical purposes: tungstic acid for coloring yellow; oxide of tungsten for coloring blue; tungstate of soda in dyeing and calico printing, and is a substitute for stannate of soda.

TUNICIA, a N. W. co. of Mississippi, bordering on the Mississippi river, which separates it from Arkansas, and intersected by the Tunica and Coldwater rivers; area, 750 sq. m.; pop. in 1860, 4,867 of whom 3,484 were slaves. The surface is flat, and in many places wampy, and the soil fertile. The productions in 1850 were 94,735 bushels of Indian corn, 3270 of sweet potatoes, and 717 bales of cotton. Capital, Austin.

TUNICATA. See MOLLUSCA, vol. xi. p. 631.

TUNIS, one of the Barbary states of N. Africa, bounded N. and E. by the Mediterranean, S. E. by Tripoli, S. by the desert of Sahara, and W. by Algeria, between lat. 31° and 7° N., and long. 8° and 11° E.; extreme length about 440 m., average breadth 160 m.; area, 70,000 sq. m.; pop. 2,500,000. Beside the capital, of the same name, the chief towns are Cairwan, Soosa, Hammamet, Bizerta, and Kaff. The coast line is irregular, and has 8 extensive indentations, forming the bays of Tunis, Hammamet, and Gabes. The only considerable river is the Mejerda (anc. Bagradas), which falls into the bay of Tunis after a N. E. course of about 100 m. Near its mouth, and for some distance W. of it, there are several large lagoons. The lake of Al-Sibbah, 70 m. long and 25 broad, near the border of the Sahara, becomes nearly dry in summer, when a layer of salt is found on its bed. The interior of Tunis is but little known. The N. W. portion is mountainous, the summits having a height in many places of 4,000 or 5,000 feet. The mountains are well timbered, and have many tracts of cultivated land and olive plantations on their lower slopes. In extensive plain or table land, 100 m. long by 30 broad and quite level, extends from this region to the gulf of Hammamet; it is nearly destitute of trees, and is used by the Arabs for pasturing their horses and camels. To the S. of this plain the country is believed to be nearly desert, though in ancient times it was celebrated for its fertility. Silver, lead, and copper are found in the mountains. The climate is very healthy; rain falls at intervals between November and April, but droughts prevail during the rest of the year. In winter the

average of the thermometer is 56° and in summer 84°, the mean of the whole year being 69°. Wheat, barley, maize, &c., are raised, but dates furnish the principal subsistence of the inhabitants. Olives, tobacco, cotton, indigo, and various drugs and dyes are grown; and all the fruits of Europe are abundant. The principal domestic animals are horned cattle, mules, and camels; the breed of horses, which was once so famous, has been allowed to degenerate. The tunny fishery on the coast is very extensive. The lion, panther, lynx, ounce, wolf, and wild horse are the principal wild animals.—The people of the interior are different tribes of Arabs and Kabyles, while those of the coast are an admixture of Turks, Moors, Jews, and renegade Christians. They are generally good-looking, but very ignorant. The language is a dialect of Arabic, but a bastard Italian is used by the traders. The Arabs resemble the Bedouins of Arabia in their mode of life, but are inhospitable to strangers. The Kabyles live on the mountains in villages of rudely constructed huts, and subsist chiefly on dates, bread, and milk. Arms are carried by all classes, and on the borders of Algeria the inhabitants do not acknowledge allegiance to either government. The religion is strict Mohammedanism. The principal manufactures are woollen fabrics, particularly the red caps so much worn along the shores of the Mediterranean; considerable numbers of skins are tanned and dyed; and some trade is carried on with Europe and the interior of Africa. The government of Tunis, though nominally dependent on Turkey, is in reality perfectly independent. The bey's power is absolute, and his will the only law known in the country. There are many ancient ruins in different parts of Tunis, more particularly on the banks of the Mejerda, where at Dukhah (anc. Thugga) there are temples, an arch, a number of cisterns, baths, barracks, gates, theatres, an aqueduct, and many inscriptions. The great aqueduct which conveyed the water 52 m. from the mountain of Zagwam to Carthage can yet be traced along the whole line, while there are portions still standing which rise to the height of 98 feet in some places. Under the Romans this country formed the province of Africa, and was divided into Zeugitana in the N. and Byzacena in the S.; and its most important cities were Carthage, Utica, Hippo Zantus (Bizerta), Leptis Minor, Thapsus, Hadrametum, and Zama.—**TUNIS**, the capital, is situated on the W. side of a lagoon at the mouth of the river Mejerda, 400 m. E. from Algiers, in lat. 36° 43' N., long. 10° 24' E.; pop. estimated at from 180,000 to 200,000. It is surrounded by a double wall 5 m. in circuit, and defended by a strong castle, which commands the approach from the sea, and by several forts. It has a very imposing appearance when viewed from a distance; but the streets are narrow and dirty, and the houses generally exceedingly mean, consisting of a single story without windows toward the streets.

The town is well supplied with water. There are many handsome mosques, and several large barracks, one of which has room for 4,000 men. There are a Moorish college and several schools, a Roman Catholic church and convent, a Greek church, a theatre, and numerous public baths and bazaars. The manufactures are principally woollen cloths and caps, embroidery, leather, and essences of musk, rose, and jasmine. An extensive trade is carried on, the principal exports being oil, caps, soap, grain, wool, hides, cattle, sponges, wax, gold dust, and ivory, and the imports cotton, linen, and woollen goods, tin, lead, iron, coffee, sugar, spices, &c. The depth of water at Tunis is only 6 or 7 feet, and vessels lie in the bay and discharge by lighters.—Tunis derives a great deal of the interest attached to it from being situated a short distance from the site of ancient Carthage; but it is itself a place of great antiquity. During the Punic wars it often changed masters. In A. D. 429 it fell into the hands of the Vandals, and about a century afterward became subject to the Greek empire, under which it remained till N. Africa was overrun by the Mohammedans about the end of the 7th century. Early in the 18th century it became independent. In 1535 Charles V. made it tributary to Spain, but in 1574 it was conquered by the Turks. The Moors ultimately enforced their right of electing their own bey, only agreeing to pay a certain tribute to the sultan of Constantinople. The pirates afterward became very daring, but in Cromwell's time received severe chastisement from the British under Admiral Blake, and afterward from France and Holland. In 1816 the Tunisians agreed, under threat of being treated as the Algerines had been by Lord Exmouth, to renounce piracy and Christian slavery. Under Achmet Bey (1837) and his successors, Mohammed Bey (1855) and Mohammed Sadyk Bey (1859), various reforms have been effected or initiated, including the suppression of the slave trade, declaring the children of slave parents free, the suppression of many monopolies and oppressive taxes, the equality of all subjects, the establishment of military conscription and of mixed tribunals, and the creation of a municipal government for the administration of affairs in the capital. French influence has long been predominant in the country and is exerted in favor of reform.

TUNKERS. See **DUNKERS**.

TUNNEL, in civil engineering, an underground passage, usually constructed for conducting a canal or road through elevated grounds. In mining the term is also sometimes applied to horizontal excavations, especially to such as have been described under the head of **ADIT**. In Europe tunnels are a more common feature upon railroads and canals than in this country, and some of the most important upon the former have been noticed in the article **RAILROAD**, vol. xiii. p. 737. On the canals of England there are 5 tunnels exceeding 3,000

yards each in length, the longest being the Marsden (Huddersfield), which is 5,500 yards long. In France there are 4 long tunnels, one of which, the Noirieu (St. Quentin canal), is 13,128 yards long, and cost only \$13.53 per yard. The Mauvages (Marne and Rhine canal), 5,320 yards long, cost \$314.60 per yard. Tunnels are no new feature in engineering either in the eastern or western hemisphere. Mention is made in the article **ARDES** of the tunnels carried through elevated points encountered by the roads constructed by the Incas of Peru; and in the article **AGRODCT** it is mentioned that they opened similar ways for the conveyance of water from the reservoirs in the mountains several hundred miles distant. The tunnels of the ancient Romans made for a similar purpose are also there noticed. Others were made by them for the drainage of lakes, one of the most remarkable of which was constructed by the emperor Claudius between Lake Fucinus (now the lake of Celano) and the river Liris (now Garigliano). This was cleared out some years since by order of the Neapolitan government, and a minute account of it, as it then appeared, is published in "Blackwood's Edinburgh Magazine," vol. xxxviii. p. 657, in a paper entitled "Eight Days in the Abruzzi." This tunnel proved to be about 3 m. long, 30 feet high, and 28 feet wide at the entrance, and nowhere less than 20 feet high, constructed in part through solid rock, and in other places lined with masonry. The excavation appears to have been conducted after the plan practised at the present time, by means of a number of vertical shafts first sunk on the line of the tunnel, from the bottom of which the work was carried on simultaneously in opposite directions. Another tunnel, made at an early period of the Roman republic for the partial drainage of the Alban lake, is more than a mile long. In Boeotia is a tunnel of very ancient date constructed for the drainage of Lake Copais. The most remarkable tunnel is that under the Thames river at London, of which further mention will be made in the course of this article.—The methods and cost of constructing tunnels vary greatly with the materials through which they penetrate. The operations are in general similar to those employed in mining, of which some account is given in the article **MINING**. They are not limited to the driving through of a horizontal passage, but long tunnels involve the necessity of sinking shafts from the surface down to their level, not merely for expediting the work in the manner alluded to above, but the shafts are almost indispensable as a means of ventilation, which is effected for some distance beyond their foot as soon as an opening can be made through them and the portion of the tunnel leading to the nearest entrance. If the ground over the tunnel rises to very great height, as in passing through the base of a mountain, shafts may be impracticable, and the work can then be pushed forward only from the two ends; and artificial means

or ventilation must be adopted, as by the use of steam or water power to drive in through large pipes a great body of air to keep the atmosphere sufficiently pure and clear from powder smoke for the men to conduct their work with safety and advantage. Short tunnels may be excavated without shafts; and if in strata easy to break and remove, with no access of large quantities of water or of quicksand, the work may be conducted at a cost not exceeding \$70 or \$80 per yard to the ordinary dimensions of railroad tunnels; indeed, some tunnels have been made at rates much less than these. The expense, however, rapidly increases with the hardness of the rock, or by its giving place to loose materials, especially of a sandy nature. With access of water these form quicksands that flow through any apertures permeable to water itself; and when these are pressed down by a column extending upward into higher grounds, their exclusion is one of the most difficult operations attending the construction of tunnels. Sometimes, in ground elsewhere solid, fissures are struck which are channels of such materials, and let them down in a continuous current of prodigious force, sweeping away every obstacle opposed to it. For such reasons work estimated and let for \$200 per yard has cost over \$650; which is about the highest expenditure paid for tunnelling, except in the case of the Thames tunnel, the expense of which was about \$6,000 per yard. In loose ground, or in rock not thoroughly bound together, so that pieces are in danger of falling, a lining of brickwork in the form of an arch, and of thickness sufficient to sustain the pressure that will come upon it, is necessary; and this is made either to follow close upon the excavation as it goes on, or, if the ground is sufficiently safe to stand till the excavation is completed, the lining may be afterward built up throughout the whole tunnel, or only in those places that need it most. In case of carrying the lining on with the excavation, it is sometimes necessary to keep a wooden lining as far in advance as practicable, and within this construct the permanent brick lining. When the floor of a tunnel is of loose material, this may be pressed upward, and springs of water may break forth threatening serious injury to the foundations of the lining and sides and floor of the work. In such cases the lining of brickwork must be extended over the whole floor, and this is done in the form of an inverted arch; the bricks are laid endwise across the arch in several courses and in hydraulic cement. It has happened in using common mortar in the brick lining of tunnels, that this before hardening has been squeezed quite out from between the bricks, letting them come together, and causing so much injury as to render the construction of an inner lining essential to save the work. The laying out a long tunnel, which is to be excavated from both ends, and from shafts sunk along its line, is often a nice piece of engineering work. Its

line is run over the surface with the transit instrument, and the range of its centre is established with the greatest exactness either upon piers especially constructed for the purpose, or upon posts firmly set in the ground. The places of the shafts are then marked on this line, and when these have been sunk perpendicularly to the required depth, two plumb lines suspended in each shaft on the central or transit line give the direction below of this line. To prevent the vibration of the plumbets, they are received at the bottom in buckets of water or cups of mercury. The transit instrument is used at the bottom to carry out the line; the magnetic needle cannot be trusted for this work on account of its liability to variation from local attraction. The tunnel may be extended from the shafts of its full size at once, or narrow headings may first be run through, and afterward enlarged. If the ground is suspected to be of a changeable character, a small drift is sometimes run quite through before any contracts are let, as by this means a correct idea is acquired of the nature of the difficulties to be encountered. As the excavation is carried out, those parts which require a lining are made as much larger than the proposed width and height of the tunnel as the thickness of the brickwork on both sides. This may consist of 8 lengths of brick, making altogether 4 feet; and in addition to this there may be a space for the primary wooden lining, which cannot in all cases be removed, but must be built in behind the brickwork. All vacant spaces behind the masonry are thoroughly tamped and rammed with earth and stone; and if the ground is very treacherous, the curvature of the sides, top, and bottom is made to approach to that of a circle, thus securing the strength of the arch figure in every direction. The shafts are left after the completion of the tunnel as chimneys for ventilation; and they are sometimes enlarged to great size with the view of transmitting the light of day into the dark passage below. The purpose they serve in the latter respect is, however, of little importance. An oblong opening termed an eye has also in some instances been carried down from the surface along the line of a tunnel for purposes of ventilation and light. In the Bishopton tunnel, England, there is such an eye 800 feet long.—The most costly of all tunnels yet completed, and probably the most useless, is that under the Thames river between Wapping and Rotherhithe, London. As early as 1798 it was proposed by Ralph Dodd, an engineer, to open a passage under the river between Gravesend and Essex; and in 1804 others proposed the locality finally selected for this enterprise. In 1807 a shaft was sunk 815 feet back from the river, and from this the tunnel was to proceed; but the work was abandoned on account of the influx of sand and water. Trevithick, the engineer, after this carried a drift under the bed of the river to the distance of 1,046 feet; it was 5 feet high, 8 feet wide at the

bottom, and $2\frac{1}{2}$ at the top. The work was stopped within about 200 feet of the opposite shore by the water breaking in. Nothing more was done until 1828, when Mr. M. I. Brunel submitted new plans, which were favorably received, and a company was formed to carry them into execution. The place selected for the commencement of the work was on the Rotherhithe shore, 150 feet from the river, where the opposite banks are but 1,000 feet apart. In order to sink a large shaft through the quicksand to the required depth, Mr. Brunel constructed a cylinder of brickwork 50 feet in external diameter, with walls 3 feet thick resting upon a curb of timber, and covered at the height of 45 feet with another similar curb, the two being tied together by 48 wrought iron screw bolts 2 inches in diameter, and the whole space between the two curbs being filled in with the brick walls. This was built upon 24 piles that were driven into the ground a little outside of the curb, and were furnished each one with a shoulder for receiving it. There was also an undercurb of cast iron, having a sharp cutting edge for penetrating the ground. The cylinder being built and the cement having become hard, the earth within was excavated, and hoisted out by means of a steam engine placed on the top of the shaft, and 16 of the piles on which the shaft rested were driven down, two opposite ones together half an inch at a time. Thus the whole went gradually down, carrying by the great weight of 910 tons the other 8 piles. All the piles were finally removed when they were no longer needed for guiding the downward movement of the shaft, and this was made to descend to the depth of 40 feet, when it became jammed by the external pressure. Below this the construction of the walls in masonry as the excavation went down was a matter of great difficulty on account of the loose character of the ground. The walls, increased to 4 feet in thickness, were built of stone laid in cement and lined with 2 courses of brick. At the depth of 80 feet a central shaft 25 feet in diameter was sunk as a well for the drainage of the tunnel. At this depth the pressure was so great as to cause the ground to give way suddenly, and a quantity of sand and water was blown up. In Jan. 1826, the excavation for the tunnel was commenced at the depth of 68 feet. This was laid out 88 feet wide and $22\frac{1}{2}$ high, and to carry such an excavation forward through loose materials charged with water to an inexhaustible extent, and under a pressure of a column 70 or 80 feet high, required appliances of an entirely novel character. In a large portion of the ground, no part of the face of the work, of the top or sides, and sometimes of the floor, could be left exposed even for a few minutes, without careful watching and the means of shutting it off immediately with a counteracting pressure superior to that exerted inward. The brickwork lining, it was evident, must follow closely upon the excavation, and it alone

could furnish the support against which the protection in front might be braced. This protection, it was also evident, must consist of a multitude of individual parts, which could be removed successively and each be replaced and pushed forward as the excavation behind admitted. The height of the tunnel required several stages for workmen to operate simultaneously, that the whole might be carried on together. These requirements were supplied in 12 great frames of cast iron, making altogether what was termed a shield, filling as they were placed side by side the whole width of the tunnel, and each extending the whole space between the floor and the roof; each could be moved forward in its turn 6 inches at a time without movement of the others, by means of powerful screws, one at the top and one at the bottom, bracing against the brickwork behind; and each frame had 8 compartments or floors one above another, each of which was occupied by a workman. The tops of all the frames and sides of the outer ones were covered with smooth iron plates, up to which the brickwork was kept as closely as possible; and the support was on flat soles which could be alipped forward with the machine. The front of each compartment or cell was protected by a series of narrow boards which might be kept close up against the end of the frame or be separately pressed forward a few inches. Each workman in his cell removed first the upper one of these boards, and excavated, for the most part with his hands, the earth thus exposed for about 6 inches inward; then replacing the board, he pushed it forward and caused it to remain by the pressure of jack screws bracing against the frame; the next board below was then removed and the operation repeated at this point, and so on; and when all had been thus carried forward, the frame itself was moved up to them. In bad ground the danger attending the removal of a single board was often very serious, as may be inferred from the fact that through apertures hardly perceptible, or not admitting a single finger, the clay would obtrude itself in a continuous current; and it was sometimes the case that the workman would be driven out of his cell, and this being then tightly closed would become entirely filled, and so would be left till the "run" was checked by operations continued in other parts. The brickwork all around the excavation was laid in concentric, independent courses within the rectangular outer portion, which conformed in shape to that of the shield, and was finished in two archways separated by a middle solid wall extending entirely through, $8\frac{1}{2}$ feet thick at the top and 4 feet at the bottom; thus making two tunnels side by side. Through this wall transverse arches form occasional openings from one tunnel to the other. The width of each tunnel at the springing of the arch is 18 feet 9 inches. The plan of the work included a carriage way and a narrow footpath along the central wall, also a lining of cement throughout. Only one archway,

however, has been thus completed.—Many interesting circumstances were connected with the construction of this tunnel. For some time the excavation was in a stratum of clay and unattended with serious difficulties. These commenced on breaking into a fissure filled with sand and gravel, the passing of which occupied 32 days. With the close of the year 1826, the first year's work in tunnelling, the progress was 350 feet. The floor of the tunnel was made to slope down at the rate of $2\frac{1}{2}$ feet in 100, in order to give sufficient depth of ground in the middle of the river above the brickwork, which however was not after all more than 10 feet. Even near the shore it was found that there was much danger of the river bursting through into the tunnel; portions of the bed frequently settled, and to fill the cavities thus formed large bags of clay were sunk in the river. Constant examinations were made of the bottom by men descending in a diving bell; and it happened that a shovel and hammer lost from the diving bell were afterward found among the earth which broke into the tunnel. The first serious accident occurred on May 12, 1827, at a distance of 544 feet from the shaft, the water rushing in with such violence that within 15 minutes the tunnel was filled and the men narrowly escaped with their lives. On examining the break with a diving bell, the arches and shield were seen to be undisturbed; and the displacement of earth was estimated at 25,000 cubic feet. The method adopted to prevent further influx of water was to cover the hole with tarpaulings, and fill in bags of clay, of which about 8,000 were used, each containing a ton. The water was then pumped out, and on June 27 the tunnel was again entered; but it was not until the end of September that matters were restored, so that the shield again began to move forward. On Jan. 12, 1828, 605 feet in, and just under the middle of the river, the water burst in so suddenly that the tunnel was almost immediately filled, and 6 workmen were drowned. Mr. Brunel, the only other person in the tunnel at the time, had a most narrow escape, being swept forward by the flood into the shaft, up which he was carried as it filled with water. The cavity in the river was filled with 4,000 tons of clay in bags, and he water was again pumped out, so that the tunnel was reentered on April 12. The funds of the company being now exhausted, a solid wall was built across the extreme end of the archways, and the work was abandoned for 7 years, during which time one of the archways was kept lighted with gas and open for exhibition. The government finally agreed to furnish the funds required, and the work was again taken up, but advanced very slowly on account of the increasing difficulties. Three more breaks occurred, and one life was lost. In Jan. 1841, the tunnel had reached the opposite bank, when the work in it was stopped until the shaft at this end could be completed. This shaft was made upon similar plans to the

other, only with a slight taper from 53 feet diameter at top to 55 feet diameter at the bottom, in order to prevent its being jammed in descending. A driftway from this shaft reached the tunnel on Aug. 18, and toward the last of November the middle frames of the shield came up to the walls of the shaft, through which they were passed in the same manner as they had passed through the ground, and the brickwork of the tunnel was soon after closed up with that of the shaft. The tunnel was opened for foot passengers on March 12, 1843. Its total length between the shafts is 1,200 feet. It was originally proposed to complete it with a carriage road winding around the shafts at a gradual descent; but it has not been deemed expedient to incur the additional expense which this would involve, and the tunnel has been used only for foot passengers who pay a toll of 1 penny each. Its total cost has been £454,714, of which £180,000 was subscribed by the original shareholders or was raised upon debentures. The receipts arising from the tolls and the renting of stalls in the cross arches scarcely amount to enough to keep the work in repair and good order.

TUNNY, a marine fish of the mackerel family, and genus *thynnus* (Cuv.). The body is elongated and compressed, with a slender tail keeled in the middle, and with 2 oblique cutaneous folds at the base of the caudal fin on each side; mouth large, with the teeth small, awl-shaped, in a single row on each jaw, and fine and crowded on the vomer and palate; there are 2 dorsals, near together, the posterior followed by 9 or 10 finlets opposite those of the anal fin; scales largest around the pectoral region, forming a kind of corset, on the anterior part of the back, and along the lateral line; cerebellum remarkably large, as would be expected in such an active fish. The common tunny of Europe (*T. vulgaris*, Cuv.) attains a length of 15 to 20 feet, and a weight of more than 1,000 lbs.; it is dark blue above, the corset lighter, sides of head white, and below grayish white spotted with silvery; 1st dorsal, pectorals, and ventrals black, the other fins mostly flesh-colored; the pectorals are scythe-shaped, and $\frac{1}{2}$ the length of the body. It is a very active and voracious fish, feeding on herring and the small migratory species; it is very abundant at the E. and W. ends of the Mediterranean, and in its narrowest portions generally, approaching the shores in summer in large shoals for the purpose of spawning; at this time they are captured in large nets arranged in a funnel-like form, into the wide mouth of which the fish enter, and, being gradually driven to the narrower end, are killed by lances and harpoons; a single line of nets often extends more than a quarter of a mile, costing about \$6,000. Its flesh is highly esteemed, being very solid, almost like meat, as firm as that of the sturgeon, but finer flavored; it is red before it is cooked, and is served at table in a great variety of ways, in all of which

It is considered delicious and wholesome; for this purpose its capture has been energetically prosecuted from the earliest antiquity. It is found also in the Atlantic and in the North sea. The ancient Byzantium was especially enriched by the tunny fishery, the gulf here, according to Ouvier, having received the name of the Golden Horn from the wealth derived from the capture of this fish, though Gibbon gives a different explanation of this name; even at the present day these waters swarm with the tunny, but the indolent Turks pay little attention to this source of food and wealth. The Phœnicians established a fishery at the other end of the Mediterranean, on the coast of Spain, at a much earlier period, and representations of the tunny are often seen on their coins and medals. A salted preparation of this fish was called by the Romans *salsamentum Sardinicum*. The principal fishery of the present time is carried on in Sicily and Sardinia. The tunny is very timid, and easily driven by loud noises to its own destruction.—The American tunny (*T. secundo-dorsalis*, Storer), called also horse mackerel and albicore, attains a length of 9 to 12 feet; it is nearly black above, silvery on the sides, and white below; gill covers and pectorals silvery gray; iris golden; ventrals black above and white below; finlets mostly yellow; the 2d dorsal is much higher than the 1st, anal further back than in the European tunny, and the pectorals shorter. It is found from New York to Nova Scotia, coming into Massachusetts bay about the middle of June and remaining through September; it gets very fat by the end of August, and is then valuable for the oil, which is obtained by boiling the head and abdomen; a single fish will thus yield about 20 gallons; it is taken by the harpoon, and affords very exciting sport, as the fish is active, strong, and tenacious of life; it feeds on menhaden and other small shoal fish; it is hated by the fishermen for its injury to their nets, and is rarely used here except for mackerel bait; the flesh, however, resembles lean pork, with a fine mackerel taste, and in time will probably be frequently seen in the markets; it is not a very common fish.—The tunny of the tropics (*T. pelamyx*, Cuv.), with other allied genera of the family, has been described under BONTRO.

TUNSTALL, or TONSTALL, OUTHBERT, an English prelate, born at Haldeford, Yorkshire, in 1474 or 1475, died at Lambeth palace, Nov. 18, 1559. He was educated at Oxford and Cambridge, became a fellow of the latter university, afterward studied at Padua, where he received the degree of LL.D., and was made rector of Harrow-on-the-Hill in 1511, and in 1515 archdeacon of Chester. In 1516 he was appointed master of the rolls, and sent to Brussels as commissioner to the emperor Charles V., with whom he concluded two treaties of alliance and commerce. After being prebendary of York and Salisbury, and dean of the latter, he was in 1522 made bishop of London, and in 1528 lord privy seal, and during the next

6 years was twice ambassador to Spain and France. In 1530 he was translated to the bishopric of Durham. He soon after resigned the privy seal, but among all the changes effected in the church by Henry VIII., and those introduced by Edward VI., he kept his place as bishop, and was also a member of the privy council and of the king's council in the north. Through the influence of the duke of Northumberland he was finally deprived of his bishopric in Oct. 1552, and committed to the tower. On the accession of Mary he was reinstated; but refusing to take the oath of supremacy on Elizabeth's accession, he was again deprived in July, 1559, and remained the guest of Parker, archbishop of Canterbury, till his death. He wrote *In Laudem Matrimonii* (4to., London, 1518); *De Arte Supputandi Libri IV.* (4to., 1522), a treatise on arithmetic, often reprinted; "Compendium and Synopsis," an abridgment of Aristotle's "Ethics" (8vo., Paris, 1554); "A Defence of Predestination" (4to., Antwerp, 1555); and a volume of prayers (8vo., 1558).

TUOLUMNE, an E. co. of California, bounded N. by the Stanislaus river and E. by the Sierra Nevada mountains, and drained by the Tuolumne river; area, about 1,500 sq. m.; pop. in 1860, 16,229. The surface is level in the W. part, and in the E. mountainous and covered with excellent timber, which is largely exported; the soil of the valleys is very fertile. The productions in 1858 were 10,740 bushels of wheat, 70,080 of barley, and 19,260 of oats. There were 30 quartz mills, 4 grist mills, and 22 saw mills. It is one of the most important mining counties of the state. Capital, Sonoma.

TUPELO, an aboriginal name applied to several species of *nyssa*. According to Prof. Gray, it belongs to the *cornaceæ* or dogwood family, comprising both trees and shrubs with simple, entire, or rarely toothed leaves, destitute of stipules; perfect or else polygamous flowers, succeeded by berries or drupes of one or two cells. The species most diffused throughout the country seems to be the *N. multiflora* of Wangenheim. (See BLACK GUM.) The large tupelo (*N. uniflora*, Walter) becomes a large tree in the swamps of North Carolina and southward; its leaves are 4 to 6 inches in length, long-petioled, ovate or oblong, entire or sometimes sharply toothed, downy beneath, or occasionally slightly cordate; the fertile blossoms borne on a single peduncle; the fruit oblong, blue, an inch or more long. Its timber is soft, and its roots so spongy and light that they are employed as buoys to fishing nets. The water tupelo (*N. aquatica*, Linn.) is likewise a large tree, found growing on the edges of ponds and in the pine barrens from North Carolina to Florida; its leaves are short-petioled, varying from lanceolate to orbicular obtuse, slightly cordate; the fertile flowers 1 or 2 on short peduncles; drupes oval, blue. The timber is of little value except for fuel. The Ogeechee lime (*N. copitata*, Walter) is a small tree, rarely exceeding 30 feet in height; its

leaves are large, short-petioled, oblong, oval, or obovate, mucronate or acute; the perfect flowers solitary on a short peduncle; drupe an inch long, oblong, red, the stone deeply striated; the pulp of an agreeable acid, from which circumstance the tree is called the lime. It occurs naturally near the sea coast in swamps from Georgia to Florida. Its berries when boiled in sirup form an agreeable preserve.—The tupelos are indigenous to North America, varying much in mode of growth, shape of the leaves, and general contour, so much so that many alleged species described by botanists are referable to a few common types. Abroad they are in esteem for ornamental planting, and are raised from seeds or layers.

TUPPER, MARTIN FARQUHAR, an English miscellaneous author, born in London, July 17, 1810. He is the son of a physician, and received his education principally at the charter-house, and at Christchurch, Oxford, where he was graduated B.A. in 1832, proceeding M.A. in 1835 and D.O.L. in 1847. He studied law at Lincoln's Inn, and in 1835 was admitted to the bar, but has never more than nominally practised the profession. He had already contributed many articles to the periodicals, when in 1837 appeared his "Proverbial Philosophy, a Book of Thoughts and Arguments originally treated," the first half of which was written in 1836 in a lawyer's chambers. This work brought him into immediate popularity, and, in spite of much severe criticism, has passed through 49 editions in England, and still commands an annual sale of 5,000 copies. In America nearly 500,000 copies have been sold, and the work has been translated into several continental languages. In 1845 he was elected a fellow of the royal society, and has also received the Prussian gold medal for science and art. Of his numerous succeeding works, both in prose and verse, the most important are: "A Modern Pyramid to commemorate a Septuagint of Worthies" (1839), a series of sonnets and essays on 70 celebrated men and women; "An Author's Mind" (1841), containing plans of 80 unpublished works; three tales on coventousness entitled respectively "The Crook of Gold," "Heart, a Social Novel," and "Twins, a Domestic Novel" (1844); "Probabilities, an Aid to Faith" (1847); and poems entitled "Hactenus," "Ballads for the Times," "Lyrics," "Things to Come," "A Dirge for Wellington," "War Ballads," "Church Ballads," "White Slavery Ballads," "International Ballads," and others which have appeared anonymously. Many of these works have passed through several editions. At the time of the great exhibition of 1851 he published in several languages a "Hymn for all Nations." During later years he has published "Rifle Ballads," in aid of the rifle club movement; "King Alfred," a patriotic play; "The Poems of King Alfred," translated from the Anglo-Saxon into the corresponding English metres; "Three Hundred Sonnets;" "Paterfamilias's Diary of

Everybody's Tour" (1856); "The Rides and Reveries of Mr. Æsop Smith;" and the novel of "Stephen Langton," a picture of England in the days of King John. He has also written fugitive poems on many topics of passing interest, and has furnished to periodical literature, including the "Quarterly Review," a considerable number of contributions. In 1851 Mr. Tupper made a visit to the United States. His life has been spent principally in retirement at his estate, inherited from his mother, in the parish of Albury, near Guildford, Surrey.

TURANIAN RACE AND LANGUAGES.

Next after the Indo-European and Semitic families of nations and languages, the most important to the linguist and ethnologist is that which is spread over the greater part of central and northern Asia, and also a not inconsiderable portion of Europe. For, though gifted with inferior capacity for advancing, or even for appropriating and profiting by civilization, it occupies a wider territory than any other race, and has played an important part in the political history of the world. Its constituent members (chiefly according to Castrén) are as follows: 1. The Finno-Hungarian or Ugrian branch. Its subdivisions are: *a*, the Ugric, including the Hungarian or Magyar as principal member, with the Vogul and Ugro-Ostiak, in and beyond the Ural; *b*, the Bulgaric, including the Tcheremizes and Mordvins, scattered tribes along the Volga; *c*, the Permian group, of the Permian, Zyrianian, and Votiak, in eastern Russia; *d*, the Finnish or Tchudic, including the Lapp, the Finnish proper, or Suomian, and the Esthonian. This is the most western branch of the family, lying chiefly within the limits of Europe; it is also the one of highest endowment, most perfect language, and most advanced culture, and more than one of its members, as the Hungarian and Finnic, are not unworthy of the place they occupy among nations of higher race. 2. The Samoyedic branch, comparatively insignificant in numbers, position, and history, and one of the lowest races of the Asiatic continent. The Samoyedes occupy the inhospitable shores of the Arctic ocean, from the White sea to beyond the North cape of Asia, and some of their tribes are still left in the northern mountains of central Asia, from which the others are supposed to have descended, following the course of the rivers northward. 3. The Turkish or Tartaric branch, the most widely spread of all, reaching from Turkey in Europe to beyond the middle of central Asia, with important outliers in the yet more remote north-east, as the Yakoots of the Lena. Its subdivisions are very numerous, but are grouped together in three chief classes: those of the south-east, in and to the east of Toorkistan or Independent Tartary; those of the north, including among others the Kirgheez, Bashkirs, and Yakoots; and those of the west, stretching from northern Persia through Asia Minor and the Crimea to Constantinople, and scattered in patches over the

European dominions of the sultan. 4. The Mongolian branch, lying yet further east. The Mongol race, since its wonderful career of conquest in the 12th and 13th centuries—in which, however, Turkish tribes were the chief agents—has shrunk again within its ancient borders, and lives in insignificance under Chinese domination. 5. The Tungusian branch; of this, the principal race is the Mantchoo, which has held China in subjection during the past two centuries.—It has been sought to extend still further the boundaries of this immense family, by attaching to it the Dravidian races of southern India, and even by tying on all the other Asiatic peoples (excepting the Chinese), the Malays and Polynesians, and the North American tribes; but such sweepingly synthetic classification is, in the present stage of linguistic ethnology, to be regarded as utterly unscientific. Even the combination of the branches above stated into one family has but recently been made with confidence.—As the Indo-European languages are much more varied and diverse in their development than the Semitic, so they are, in their turn, vastly exceeded in this respect by the idioms now under consideration. The law of linguistic connection prevailing among the latter is quite peculiar; between tribes confessedly of near kin exist differences of linguistic material even in cardinal points, such as the pronouns, numerals, and important affixes of derivation. A marked similarity of linguistic method, however, runs through them all, and helps to stamp them as kindred. They are all formed on what is called the agglutinative type; that is to say, the root or theme everywhere maintains its form almost unchanged, and all formative syllables are suffixed, never prefixed, to it; and they enter with it into no close and intimate union, giving rise to forms which are accepted by the mind, without analysis, as signs for the complex idea; they remain in the condition of loosely appended elements. There are no varieties and irregularities of nominal and verbal flexion; each language has but a single declension and a single conjugation. The plural of declension is formed by a pluralizing particle, to which the same case-endings are then attached as in the singular. Grammatical gender is a thing unknown. The cases are numerous. Prepositions always follow the words they govern; as, indeed, it is a general rule that the governed word precedes the governing. Words connecting sentences—relatives and conjunctions—are hardly employed at all. A marked phonetic peculiarity running through all the dialects is the law of harmonic sequence of vowels; the vowels are divided into two classes, heavy and light, and within the same word only heavy or only light vowels can follow one another; the vowel of a suffix, or those of a series of suffixes, changing to conform themselves to the character of that of the root. The languages are rich in harmonious and well developed vocabularies, so far as the sound goes, and they

abound in nice distinctions of certain kinds; yet their rank in the general scale of language is but a low one; they are deficient in sharp distinction of the principal grammatical categories, and awkward, cumbrous, and incomplete in the expression of thought. This character belongs to them in varying degree; the Mantchoo dialects are the poorest of all, and the Mongol do not much surpass them; the Tartaric idioms hold the middle rank; the tongues of the Finnish branch, particularly the Finnish proper and the Hungarian, possess a marked superiority to the others. Most of the languages of the family are known only in their present condition, having no monuments by which their history can be followed back into the past. A properly national literature none of the branches has ever had, if we except the mythic and legendary songs of the Finns, recently collected from the mouths of the people, and combined to form the *Kalevala*, and the mostly lyric popular songs of the Hungarians; but even some of the remoter tribes have, under their influence and by the aid of foreign teachers, acquired the arts of writing, and have brought forth religious and historical works, while the Hungarian and the Turkish have developed important literatures. It is also asserted within a few years past, that on the coniform monuments of Mesopotamia and Persia is represented, in the inscriptions of the third order, an Ugrian dialect, and that we have there authentic evidence and remains of an ancient Ugrian civilization, which is even asserted to have preceded and formed the basis for that of the other races in the same region. These results of a small number of investigators are not yet fully accepted by scholars in general; if they shall prove true, they will constitute a fact of the highest consequence in the history of this family, and indeed in that of the human race, and will modify many of the hitherto prevailing opinions of ethnologists.—Respecting the name by which the whole family should be called, there is great diversity of opinion. By some it is named from one of its principal branches, or from more than one, and is styled the Mongolian, the Tartaric, the Finno-Tartaric, the Finno-Tungusian race, &c. Others entitle it the Altaic, from the mountain chain which is regarded as the original home of the tribes, and the starting point of their migrations; or, adding the name of the other mountain chain which furnished a new basis for the dispersion of some of its most important members, they know it as the Uralo-Altaic, or Ugro-Altaic. A common appellation, also, and one which has as much in its favor and as little against it as any other, is Scythic or Scythian, taken from the name given by the Greeks to the wild tribes of the north-east, who were probably, at least in great part, of this race. The authority of Max Müller has recently given currency to the name Turanian, which stands at the head of our article, although we are far from regarding it as the one most worthy of

acceptance. It is derived from the traditions of the Iranian or Persian race, in whose national recollections the contest between Iran and Turan, the Aryan race and its Tartar neighbors and foes, is an element of prime importance.—Writers upon this whole family of nations are especially Rémusat, *Recherches sur les langues Tartares* (Paris, 1820); Rask, in several of his philological works; Schott, in numerous memoirs published by the Berlin academy, especially *Ueber das Altaische-oder Finisch-Tatarische Sprachengeschlecht* (1849); Richard, in vol. iii. of his "Researches into the Physical History of Mankind;" Castrén, in a series of grammars, essays, accounts of travel, &c. (St. Petersburg, 1855-'8); and Max Müller, "Letter on the Turanian Languages," in Bunsen's "Philosophy of Universal History," vol. i., and "Lectures on the Science of Language" (London, 1861).

TURBAN (Turk. *tulbend* or *dulbend*), a covering for the head worn among most eastern peoples. It varies much in shape among various nations and classes; its usual form is that of a roll of cloth twisted around a cap. The Turks in recent times have generally abandoned it for the fez or red skull cap. The turban of the sultan was ornamented with three heron's feathers and a great quantity of gems, and an officer called the *dulbend aga* was appointed especially to take care of it. The grand vizier was entitled to wear two heron's feathers in his turban, and inferior officers one. The emirs were distinguished by green turbans.

TURBINE (Fr., a shell of spiral form), a submerged, horizontal water wheel, of the class of reaction wheels, with curved vertical buckets or floats, and the revolution of which without and around a fixed horizontal disk, having upon it guides giving direction to the impelling body of water, is made to turn a vertical axis or shaft running through the common centre of the wheel and disk, and by connections from this shaft to give motion to machinery of various kinds. The earlier, and until recently the more common forms of water wheel, were characterized in general by their having the axis horizontal, and by deriving their motion from simple weight or momentum of the water, or from both combined. Since, however, a vertical axis will, in the case of mills or grinding, serve to give motion directly or very nearly so to a millstone, the means of securing effective horizontal wheels with vertical axes have, especially in the grain-producing provinces of France and other parts of Europe, long engaged attention. In the arrangement known in England as "Barker's mill," a horizontal hollow tube receiving and discharging water from a hollow vertical shaft which turns with it, and the ends of the tube opening for discharge in opposite directions, the pressure due to combined effect of height of column and centrifugal force is relieved at each opening, but felt upon the side of the tube opposed to it; the reaction or recoil upon these

surfaces gives to the tube and hence to the shaft a rapid revolution; but the form is seldom or never used in practice. The "spoon wheel," used in France, consists of a number of separate curved blades diverging horizontally from the upright axis, upon which a descending stream of water is directed; it gives a fair percentage of work, where the supply and fall are not great. Somewhat similar to both these in principle is the turbine, invented, or perhaps first brought to effective and economical working, by Fourneyron, about 1834. (See *FOURNEYRON*.) In the employment of the turbine there are two reservoirs or bodies of water at different levels, the wheel and disk already referred to being submerged in the lower of these, and the water, conducted by a flume or large tube from the upper reservoir, is made to descend vertically through a hollow cylinder upon the disk or fixed and solid circular plate lying beneath this; the cylinder not reaching down quite to this disk, there is a lateral circular opening of no great depth completely around and between the two. Immediately without and enclosing or facing this circular opening is the depth (at its inner periphery) of the horizontal wheel, which is thus annular in form, and turns round and without the disk and cylinder. This wheel consists of an upper and under crown, horizontal and of annular form, in the open space between which (usually less, or not much more, than a foot in total depth) are fixed vertically, and running from crown to crown, curved floats or buckets, in form corresponding to those of Poncelet's undershot wheel. The upright fixed guides upon the disk direct the issuing stream of water against the curved floats of the wheel; and as it emerges on all sides, it acts upon all the floats at the same moment and constantly, moving the wheel by one horizontal component of the several pressures on these in the direction of their convex surfaces; a strong circular plate from the wheel descends slightly below the disk, attaching to and moving the solid vertical axis. This axis rises through the cylinder, emerging within a suitable box from the water space to the mechanism above. Its lower pivot is sometimes rested upon a stout lever of the second kind, and near the fulcrum, by connections with which lever the wheel can be raised or lowered alongside of the opening for the escaping water. A movable hollow cylinder, called the regulating gate, can be raised or lowered along the fixed cylinder, so as to diminish when desired the depth of opening and volume of discharge upon the wheel; and in some forms, to prevent the carrying round of dead water in the wheel above this opening, the space between the crowns is divided by a succession of horizontal plates into a number of compartments, so many of which only will be filled as correspond to the opening. The guides upon the fixed disk are also curved in a manner similar to that of the buckets, but in the opposite direction; the result is that the water does not

escape radially, but tangentially, and in such course as to strike the buckets almost perpendicularly, thus very greatly increasing its action upon the wheel. In Callon's turbine, the flow into the wheel is regulated by a series of sliding shutters, portions or the whole of which can be let down to cover the opening to the wheel. In Fontaine's improved form, shown in the London exhibition, 1851, the wheel has its floats curving horizontally, and the water descends nearly vertically upon these, but directed against them, its horizontal component of pressure taking effect; this form has some peculiar advantages. The turbines of Jonval and some others are also well known; and the name is sometimes given to Thomson's externally fed wheel, and to others differing from the more usual forms. Fourneyron's turbine, under good conditions, utilized a larger percentage of the force of water than the best ordinary water wheels, namely, from 75 to 80 per cent.; the performance of Fontaine's and of Jonval's is about the same. Among obvious advantages of turbine wheels are these: 1, they occupy little space; 2, the action on the wheel is uniform and uninterrupted; 3, the wheel turning, usually, completely within water, and the pressure outward on the floats being the same in all directions, there is no strain or increased friction in a particular direction upon the axis; 4, turning with great speed, it may directly carry the millstone in flouring mills; 5, being submerged, its performance is uninterrupted by ice, and is little affected by floods or by drought so long as the wheel is covered; 6, it utilizes a larger percentage of the power than ordinary wheels; and 7, its efficiency does not decrease in the same ratio with the velocity, when the height or volume of water is reduced: thus, a wheel at Sainte-Blaise, diameter 22 inches, under a fall of 850 feet, gave 40 horse power, equal to $\frac{1}{4}$ of the whole power of the water; while another at Gisors, with a fall of $3\frac{1}{4}$ feet, gave $\frac{1}{2}$, with one of 2 feet, $\frac{3}{4}$, and of 1 foot, $\frac{2}{3}$, of the whole power.—In the United States, water wheels of the ordinary forms were almost exclusively in use, and among the large manufacturing establishments in New England entirely so, until the year 1844, the breast wheel being regarded as the most efficient practicable. In 1843 Mr. Ellwood Morris communicated to the "Journal of the Franklin Institute," in which several articles in relation to the French reaction wheels had previously appeared, a translation of Morin's "Experiments on Turbines," with an account of some experiments also on two turbines constructed from his own designs; the useful effect of one of these was .75. In 1844 Mr. Uriah A. Boyden, a hydraulic engineer, of Massachusetts, produced for the Appleton company's cotton mills in Lowell a turbine involving several improvements, and of which the efficiency was .78 of the power. In 1846 he had constructed upon his designs, embracing further improvements, three turbines

of about 190 horse power each, for the same company; the mean maximum effective power of two of these, carefully tested, was .88 of the power of the water expended—a remarkable advance upon all previous results; and these turbines have continued to perform satisfactorily. The chief features of difference of these wheels from the original one of Fourneyron may be briefly summed up as follows: The flume conducting the water to the turbine is in form of an inverted truncated cone, the water introduced above on one side of the axis of the turbine and cone, and by a gradual curve, so that the water descends with almost no loss of power, save from friction, acquiring an increasing velocity and a spiral movement in the direction of the revolution of the wheel; the guides are accordingly a little inclined backward, so that the water shall meet their edges only. One of the most important parts of the invention is the addition without and around the wheel of two broad stationary disks, the space between which at their inner periphery is very little greater than that between the crowns of the wheel at the part next to them, but which curve outward and apart, so that the space at their exterior periphery is twice as great; the total diameter of these disks being about twice that of the wheel. When the regulating gate is raised to full height, the section through which the water passes in escaping from the wheel is thus gradually enlarged, in a ratio from 1 to 4; hence the action of the water should fall within the same distance from 1 to $\frac{1}{16}$, providing the disks be wholly submerged. This arrangement is called the diffuser; its effect is to diminish the pressure against the water escaping from the outer edge of the wheel, and thus to increase the power in the same ratio as by a certain increase in the available fall. Its principle is thus similar to that of diverging conical tubes for delivery of liquids. (See HYDRO-MECHANICS.) Its theoretical advantage is a gain of .05 power; but, probably owing to irregular movements of the water, the gain practically is about .03 of the power. Mr. Boyden also, by means of a peculiar box with bearings of soft or babbitt metal, suspends the wheel from the top of the vertical shaft, instead of running it on a step at the bottom; while by grooves and mortises the buckets are so firmly fixed between the crowns of the wheel, as to allow them to be much thinner, and to secure a freer passage for the water. In a turbine of this pattern, made in 1851 for the Tremont mills, the guides are 33 in number; the buckets 44; the least height between the crowns, .8743 ft.; greatest height, .9368 ft.; total diameter of the wheel, 8.333 ft.; diameter between inner edges of wheel, 6.75 ft.; diameter of the lower part of the disk, 6.729 ft.; diameter of the wrought iron turned shaft in different parts, 7 to 8 inches. Upon this turbine a series of extremely careful experiments was made, the various data being noted by several observers at the same time,

d accurately compared by marking the time brief intervals. The experiments embrace the quantity of water discharged, the velocity of the wheel, the percentage of power (maximum, in this case, 79%) utilized, &c.—For further details and rules respecting the construction and proportioning of turbines, as well as a full account of the experiments referred to, and the results, and of others in relation to the vent wheels and the flow of water over them, see "Lowell Hydraulic Experiments" (Boston, 1855).

TURBOT, a marine, soft-rayed fish of the flatfish family, and genus *rhombus* (Ouv.), characterized by minute sharp teeth on the jaws and pharynx, the dorsal fin commencing on the head in front of the eyes, and like the anal extending to the tail, and with the eyes on the left side. The European turbot (*R. maximus*, Ouv.), the finest of the family, sometimes measures 6 feet in width, and weighs over 200 lbs.; the left side is brown and covered with small tubercles, and the right side or lower surface smooth and white; without the tail the body is nearly round; mouth large, opening obliquely upward; eyes in a vertical line, one over the other; gill openings large; pectorals small. It keeps on sandy grounds, and is a great wanderer, usually in companies, living near the bottom, and feeding on small fish, crustaceans, and mollusks; though voracious, it is particular in its choice of food, and will bite at none but fresh bait; the spawning season is about August, after which it soon recovers its good condition. Its flesh is white, fat, laky, and delicate, and has been highly esteemed from remote antiquity; it is disputed whether this or the next species was the *rhombus* of the ancient Romans; the French call it water or sea pheasant on account of its fine flavor. Though not uncommon on the coasts of Great Britain, most of the turbot sold in the English markets are caught by Dutch fishermen on the long line of sandy banks between England and Holland; the value sent to London market from this source alone is annually not far from \$500,000. The fishery begins about the end of March and closes by the middle of August, and is prosecuted both by lines and trawl nets; the hooks are baited with smelts or other small and bright fishes; each Dutch boat brings from 100 to 150 fish, usually weighing each 5 to 10 lbs. In the time of Pennant there was a famous fishery of turbot at Scarborough; to each boat were 8 men, and each man with 8 lines, and each line with 250 hooks; the 9 lines were fastened together and extended at full length across the current, and allowed to remain out 6 hours; a great many fish were caught in this way.—The brill, pearl, or smooth turbot (*R. vulgaris*, Cuv.) is a smaller and less delicate species, with smooth scales from the same localities and caught in the same manner; the under jaw is the longer, and the upper eye a little behind the lower; it is reddish sandy brown, varied with darker,

and sprinkled with white pearl-like specks; under surface smooth and white; it is found in the Mediterranean, as are several other species still less esteemed.—The American or spotted turbot (*R. maculatus*, Girard; *pleuronectes*, De Kay), called also New York plaice and watery flounder, is from 12 to 18 inches long, and 6 to 8 wide, though sometimes attaining a weight of 20 lbs.; it is smooth, on the left side reddish gray with large circular or oblong darker blotches surrounded by a lighter margin, and with numerous white spots, especially on the fins; the lower surface white and spotless; iris silvery; gape wide, with a single row of separate, large, sharp teeth, and a protuberance on the chin; ends of dorsal rays free; body elongated; it resembles the brill more than any other European species. It occurs along the coast of the New England and middle states, and is sometimes taken by mackerel fishers near the shore; it is considered a delicate article of food.

TURENNE, HENRI DE LA TOUR D'AUVERGNE, vicomte de, a French marshal, born in Sedan, Sept. 11, 1611, killed near Sulzbach, Bavaria, July 26, 1675. He was the second son of Henri de Bouillon, prince of Sedan, by Elizabeth of Nassau, daughter of William I. of Orange, and was sent when a boy to Holland, where he learned the art of war under his uncle Maurice. In 1630, visiting the court of France in the interest of his brother Frédéric de Bouillon, he was induced by Cardinal Richelieu to enter the service of France, received the command of an infantry regiment, distinguished himself in Lorraine under Marshal de La Force, became major-general in 1634, and served under La Valette in Germany, where in 1635 he relieved Mentz, then besieged by the imperialists. In 1637, with an auxiliary corps, he joined the Swedish army under Duke Bernard of Weimar, and during this campaign captured several towns, including the stronghold of Brisach. In 1639 he was made lieutenant-general and ordered to Italy, where, under the count d'Harcourt, he defeated the united Austrians and Spaniards at Casale, and forced Turin to surrender in 1640. In 1642 he had the chief command of the French army in Roussillon, and conquered that province from Spain. After the death of Richelieu and Louis XIII. he was made marshal of France, and placed in command of the French army in Germany. He crossed the Rhine, worsted the Bavarians under Mercy, acted in concert with the prince of Condé in the 3 days' battle at Freiburg (1644), was defeated by Mercy at Mergentheim, May 5, 1645, but gained a victory over him in conjunction with Condé at Auersheim, near Nördlingen, 8 months later, and, joining the Swedish general Wrangel, conquered the Bavarians at Lavingen and Zusmarshausen, and forced the elector to sign an armistice, in March, 1647. He then repaired to Flanders, and by taking several places aided in bringing about the peace of Westphalia (1648). On his return

to France, his love for the duchess de Longueville and his brother's example connected him with the Fronde. At the head of a Spanish army which was sent to support the rebels, he was defeated near R  thel by Marshal Duplessis-Praslin, and driven out of France (1650). After trying unsuccessfully to bring about a reconciliation between France and Spain, he solicited and obtained a pardon from the French government, returned to his country, and henceforth proved the most loyal supporter of the king, while Cond   was the leader of the Frondeurs. He defeated the troops of his illustrious opponent at Bl  neau, near the Loire, in April, 1652, followed him up to Paris, inflicted upon him a most severe loss in July in the faubourg St. Antoine, and thus secured the triumph of the royal cause at home. The Spaniards having invaded the north of France under the leadership of Cond  , he marched against them, worsted them at Arras in 1654, gained the decisive victory of the "Dunes," June 14, 1658, took possession of Dunkirk, and by these and other successes hastened the peace of the Pyr  n  es, Nov. 7, 1659. He had been previously made minister of state, and now received the title of marshal-general of the camps and armies of France. In 1667, war being declared against Spain under pretence of vindicating the hereditary rights of Maria Theresa, the wife of Louis XIV., Turenne entered Flanders at the head of the French army, accompanied by the king himself, and in less than three months achieved the conquest of that province; and several of the cities he had taken were secured to France by the treaty of Aix la Chapelle, May 2, 1668. In the war against Holland (1672) he commanded one of the armies that marched into that country; and when the European powers came to its rescue, he entered Germany, advanced to the Elbe, and forced the elector of Brandenburg to a separate peace at Vosse in 1678; then, in a campaign which is considered a masterpiece of strategy, he protected Alsace from invasion, crossed the Rhine at Philippsburg, routed the enemy at Sinzheim and Ladenburg (1674), and drove them back to the Main, and, under orders from Louvois, devastated the Palatinate, laying 80 towns in ashes. In the following winter, with an army of scarcely 22,000 men, he nearly destroyed 60,000 Austrians and Brandenburgers under Beurnonville, gaining victories at Mulhouse, Colmar, and T  rkheim (Jan. 5, 1675). He now wished to retire from active service; but he was the only French general who could successfully oppose the celebrated Montecuculi, and yielding to the king's entreaties, he continued in command, and during 4 months the manoeuvres and strategic operations of the two opposing generals were subjects of general admiration. Finally Turenne forced his rival into a position near Sulzbach where he was constrained to fight at a disadvantage; the French commander consequently had a new victory in prospect, when, surveying the last

preparations for the battle which was to take place on the morrow, he was struck in the body by a stray ball, and his death caused his army to fall back beyond the Rhine. His remains were taken to St. Denis, and interred amid the royal tombs. When these were broken open during the revolution, his corpse was found in a perfect state of preservation and taken to a collection of antiquities, where it remained until 1801, when Bonaparte had it transferred to the church of the Invalides. Turenne was originally a Protestant, but became a Catholic in 1668 through the instruction and influence of Bossuet. His life was written by Sandras, Raguenet, and Ramsay. He left *M  moires* on his campaigns from 1649 to 1658, found in Ramsay's biography, and *Lettres et M  moires* (2 vols. fol., Paris, 1789).

TURGENEFF, IVAN SERGEEVICH, a Russian novelist, born in Orel, Nov. 9, 1818. He was educated at Moscow and at St. Petersburg, and in 1838 went to Berlin to finish his studies. On his return to Russia he obtained a situation in the department of the interior, and made himself known by several national songs, which became very popular; but in consequence of the sentiments expressed in one of them he was disgraced and sent into exile, and from 1847 to 1850 he lived in Germany and France. He has written poems entitled "Panascha" (1843) and "Conversation" (1844); "Memoirs, or Journal of a Sportsman" (2 vols., 1853), twice translated into French; *Sc  nes de la vie Russe* (3 vols. 18mo., Paris, 1858); and *Une nich  e de gentil-homme* (1859), beside various comedies, poems, and articles contributed to the Russian reviews.

TURGENEFF, NICOLOI, a Russian author, born in 1790. He was educated at G  ttingen, was attached as Russian commissioner to Baron Stein's provisional administration of the reconquered German provinces, was made state councillor, and, being placed at the head of the department of the interior and of economic affairs, devoted himself with ardor to the promotion of schemes for the emancipation of the serfs. In 1819 he joined the "Society of Public Good," founded by Irubetzkoi and Muraviev, and was in consequence involved in the conspiracy of 1825 and condemned to death. He fled to France, and has since resided in Paris. In 1847 and 1848 he published *La Russie et Les Russes*, divided into three parts, viz.: *M  moires d'un proconsul*, *Tableau politique et social de la Russie*, and *De l'avenir de la Russie* (3 vols. 8vo.). He has recently published a pamphlet entitled *La Russie en pr  sence de la crise Europ  enne*, and also "The Last Word on the Emancipation of the Serfs in Russia" (1860).

TURGOT, ANNE ROBERT JACQUES, baron de l'Aulne, a French philosopher and statesman, born in Paris, May 10, 1727, died March 20, 1781. He was educated for the church, and in 1749 became prior of the Sorbonne. In the same year he published a "Letter upon Paper-Money," and abandoning the clerical profession in 1774.

he studied law, and in 1758 became counsellor in the parliament and master of requests. Qualifying himself for administrative functions by special attention to natural philosophy, agriculture, manufactures, and commerce, he expounded his views upon the last three subjects in several papers which appeared in the *Encyclopédie* or in pamphlet form. The most remarkable among the latter is the *Conciliateur, ou lettre d'un ecclésiastique à un magistrat sur la tolérance civile* (1754). In 1761 he was appointed intendant of Limousin, and introduced many important reforms in the administration of that province; free transport was allowed to corn and breadstuffs, taxes were alleviated, roads and highways improved, and workhouses and charitable institutions established. In 1766 appeared his *Réflexions sur la formation et la distribution des richesses*, his chief work on political economy. He also published valuable papers on loans and on mines, beside his *Lettres sur la liberté du commerce des grains*. On the accession of Louis XVI. he was called to the navy department; and one month later, Aug. 24, 1774, he was appointed comptroller-general of finances, and undertook to introduce reforms on a large scale. In a letter to the king which was then published, he gave a synopsis of his intended policy; he desired to improve the financial condition of the kingdom by wise economy and integrity; he insisted upon the freedom of labor at home and of trade abroad, and aimed at substituting for taxes on a multitude of articles a single tax on land. Encouraged by Louis XVI., he went to work with tact, prudence, and energy; but these reforms were obnoxious to courtiers and many others. In 1775, troubles having arisen on account of the high price of breadstuffs, he was charged with having caused scarcity by his regulations respecting the grain trade. In Jan. 1776, he caused an edict to be issued, abolishing compulsory labor for the state, internal duties on breadstuffs, the privileges of trading corporations, &c.; but this only increased the number of his enemies; the privileged classes affected by it, the nobles, the clergy, and the chief tradesmen, were so loud in their complaints that the king was afraid to support his minister any longer. Turgot was consequently dismissed in May, and retired to private life, devoting his leisure to science, literature, and philosophy. He was an honorary member of the academy of inscriptions. His *Œuvres complètes*, published by Dupont de Nemours (9 vols. 8vo., Paris, 1808-'11), were reprinted under the supervision of Eugène Daire (2 vols. 8vo., 1844). His biography was written by Condorcet (London, 1796).

TURIN (It. *Torino*; anc. *Augusta Taurinorum*), a city of Piedmont, capital of the kingdom of Italy and of a province of its name, situated in an extensive plain enclosed on all sides except the N. E. by the Alps, at the junction of the Dora-Susina with the Po, 79 m. W. S. W. from Milan; pop. in 1858, 179,635. The

Po is crossed by 8 bridges and the Dora-Susina by 2, one of the latter being a magnificent structure of a single arch with a span of 150 feet. Turin is of oblong form, about $1\frac{1}{2}$ m. long and $\frac{1}{4}$ m. broad, and is defended by a very strong citadel on the W. The old town has narrow, crooked streets, and ill-built houses. In the new town the streets are broad and cross each other at right angles; and the houses are generally 4 or 5 stories in height, and many of them decorated with sculptures and other ornaments. The approach to Turin from the W. is by a fine avenue, one of the longest in Europe; and there are 18 public squares, the most important of which are the Piazza del Castello, the Piazza di San Carlo, the Piazza di San Giovanni, and the Piazza dell' Erbe. The first of these squares lies near the centre of the town, is almost surrounded by lofty palaces, and derives its name from having in its centre the old palace of the dukes of Savoy, considered one of the finest in Turin; the modern palace, at the N. side of the square, is an extensive building, contains a fine collection of paintings, and has large gardens attached. The theatre, which was built from designs by Alfieri, stands on the E. side. The Piazza di San Carlo is almost entirely surrounded by arcades, and contains a statue of Emanuel Philibert, duke of Savoy, by Marochetti. The buildings of Turin are mostly of brick. The city is not rich in ancient edifices, but many of the modern public buildings are very magnificent. The *duomo* or cathedral of St. John the Baptist, built in the 16th century, is small, and principally remarkable for the beautiful arabesques in the pilasters which adorn the front. The interior has recently been richly decorated with frescoes, and contains some fine paintings. Near it is the chapel of Santo Sudario, a small round building, considered a masterpiece of Guarini. The other churches most worthy of notice are San Filippo Neri, the largest and one of the finest in the town; San Domenico, which contains a fine Virgin and child by Guercino; San Tommaso, of little architectural merit, but possessed of some fine paintings; Santa Cristiana, with a fine façade by Juvara; Corpus Domini, highly ornamented in the interior with marble, gilding, and other decorations; and La Gran Madre di Dio, built in imitation of the Pantheon at Rome, to commemorate the restoration of the royal family in 1814. A Protestant church in the Lombard style was erected in 1858. There are in all 110 churches and chapels; and there were formerly many monasteries and nunneries, but they have been suppressed with the exception of those that are actually engaged in works of charity. Other buildings which deserve notice are the Palazzo degli Archivi Reali or register office, an extensive edifice by Juvara; the custom house, town house, and court house. The senate holds its meetings in the ancient ducal palace, and the chamber of deputies in the Carignan palace, formerly the residence of the royal princes.

The university of Turin was founded in 1412, and is a magnificent building, with a quadrangle surrounded by arcades in which are a number of ancient sculptures and inscriptions. It has a library of 112,000 volumes and 2,000 MSS., originally formed by the dukes of Savoy; a valuable collection of pictures and medals, an excellent Egyptian museum, museums of anatomy and natural history, and a good botanic garden. It has faculties of theology, law, medicine, surgery, and arts, with 84 professors, and in 1858-'9 was attended by 1,376 students. The royal academy of sciences was founded in 1783, and consists of 40 members; it has valuable collections in mineralogy, zoology, and antiquities. There are also an episcopal seminary, a royal military academy, two colleges, numerous elementary schools, and institutions for the deaf, dumb, and blind. The most important charitable foundations are the Retiro delle Rosine, where 400 girls are maintained chiefly by their own industry; the general hospital; the charity hospital, which accommodates 1,500 inmates; the Reale Albergo di Virtù, an industrial school; the Regio Manicomio or lunatic asylum; the Spedale di San Luigi, which receives many inmates and gives relief to a great number of out-door patients; and the Compagnia di San Paolo, established for a great number of objects, including education, marriage portions, and the relief of secret poverty.—The manufactures of Turin include linen, woollen, cotton, and silk goods, leather, paper, glass, china, hardware, carriages, arms, musical and other instruments; and there are numerous distilleries, dye works, and different kinds of mills. The wealth of the city is principally derived from its trade in silk; beside which the commerce includes different manufactured articles, wine, liquors, grain, and fruit. Turin is connected by railway with Genoa, Alessandria, Novara, Cuneo, Pinerolo, and Susa. Italian is the language used in official transactions, and both it and French are spoken by the upper classes; but the people generally speak a Piedmontese dialect.—Turin is supposed to have been founded by a tribe called Taurini or Taurisci, of Transalpine origin. Hannibal subdued the surrounding country, but after he retired from Italy the Romans reoccupied it and made Turin a colony under the name of Colonia Julia, which was afterward changed to Augusta Taurinorum in honor of Augustus. Turin was sacked by the Goths, and afterward by the Lombards; and it subsequently passed into the hands of Charlemagne, who conferred it in feudal tenure on its bishops, several of whom ruled it tyrannically. It was afterward governed by the marquises of Susa, and passed by marriage with the heiress of that family to the counts of Savoy. In 1281 it became the capital of the states of the house of Savoy, which with some slight interruptions it has ever since remained.

TÜRK, KARL CHRISTIAN WILHELM VON, a German educator and philanthropist, born in

Meiningen, Jan. 8, 1774, died near Berlin, July 31, 1846. He was educated at Jena, and after completing his legal studies was appointed by the prince of Mecklenburg in 1794 chancery auditor, and in 1796 chamberlain and chancery councillor. In 1800 the supervision of the school system of Mecklenburg was added to his other duties. In 1804 he visited Pestalozzi at Mitten-Buchsee, and on his return to Mecklenburg collected a company of boys, whom he taught two hours a day, instructing the teachers also in Pestalozzi's method. In 1806 he was appointed justice and consistory councillor by the duke of Oldenburg, and there renewed his teaching, to the dissatisfaction of the duke. Resigning his place, he gave himself up wholly to the business of teaching, visiting Pestalozzi again, and for a time becoming a teacher in his school at Yverdun, and subsequently establishing a school of his own at the castle of Veray, on the lake of Geneva. In 1814 he disposed of this, and in 1815 was appointed royal and school councillor by the Prussian government, first at Frankfurt-on-the-Oder, and afterward at Potsdam. Here he labored zealously to introduce Pestalozzi's method into Prussia, and with great success. He also introduced the culture of the mulberry and the raising of silkworms, and invented machines for reeling silk from the cocoons. In 1833 he resigned his post (the king granting him his full salary as a pension), to superintend the institutions he had founded. These were, a swimming school at Potsdam; an association for the improvement of silk-growing; a fund for school teachers' widows, to which he devoted the profits of some of his works; a society at Potsdam for the support of poor young men devoted to the arts and sciences; three orphan houses, one for boys and another for girls, orphans of government officers and teachers of the higher grades who were left destitute, and a third for the orphan children of artisans and teachers and officers of lower grades; and a soup distribution institution, for the old, sick, feeble, poor, and lying-in women. To these institutions he gave not only the profits of his published works, and the receipts from the sale of his gallery of paintings, but the greater part of his property and the proceeds of his autobiography, which he directed should be published after his death for their benefit. Von Türk's works are: "Letters from Mitten-Buchsee" (Leipzig, 1808), an account of Pestalozzi's method; *Die sinnlichen Wahrnehmungen* ("Perception by the Senses," 1810); "Guide to Instruction in Arithmetic" (Frankfurt, 1817), which is a valuable text book for teachers, and has passed through many editions; several essays on rearing silkworms and the growth of the mulberry; and his autobiography.

TURKEY (*meleagris*, Linn.), a well known gallinaceous bird, the type of the family *meleagrina*, which contains also the Guinea fowl (*numida*). The bill is moderate and strong, shorter than the head, compressed on the sides,

with culmen arched, and upper mandible overhanging the lower; the cere is elongated into loose, pendulous, round, fleshy caruncle; head and upper neck bare, with only a few scattered hairs, and carunculated; base of lower mandible sometimes wattled; a tuft of long, black bristles on the breast, largest in the males; wing short and rounded, the 1st 4 quills graduated, and the 5th and 6th the longest; bill broad and rounded, pendent during repose, but capable of being raised and extended like a snout; tarsi robust, longer than middle toe, covered in front with broad, divided scales, and armed with a short obtuse spur; anterior toes united at base by a membrane, the inner the shortest, the posterior moderate and elevated; claws short and slightly curved. All the species in the wild state are indigenous to North America. The common wild turkey (*M. gallopavo*, Linn.) is about 3½ feet long and 5 in extent of wings, weighing from 15 to 20 lbs., and sometimes more; the naked skin of the head and neck is livid blue, and the excrescences purplish red; the general color is copper bronze, with green and metallic reflections, each feather with a velvet-black margin; quills brown, closely barred with white; tail feathers chestnut, narrowly barred with black, and the tip with a very wide subterminal black bar; the female is smaller and less brilliant, without spurs, often without bristles on the breast, and with a smaller fleshy process above the base of the bill. It has a crop and gizzard, and an intestine 4 times the length of the body; the cartilaginous tissue of the stomach is less hard than in that of the common fowl. The full plumage is attained at the 3d year; the females usually weigh about 9 lbs. They fly in flocks of many hundreds, frequenting woods by day, feeding on acorns, all kinds of grain, buds, berries, fruits, nuts, grass, insects, and even young rogs; they make considerable journeys in search of food, flying and swimming across rivers of a mile in width; though able to reach with ease the tops of the highest trees, their flight is heavy, and would prevent their passage across any considerable expanse of ocean; they are so strong as not to be easily held when slightly wounded; they perch at night on trees. Quitting the woods in September, they come into the more open and cultivated districts, when they are killed in great numbers; they were formerly abundant in the middle, southern, and western states, but are now rare except in thinly settled regions, and have never been found west of the Rocky mountains. Benjamin Franklin thought the wild turkey should have been the emblem of the United States, being a truly indigenous and national bird; in his time the log cabin of the pioneer was surrounded by these birds, saluting each other in early morning from the tops of the forest trees, as the cottage of the European farmer is by chattering. Although exclusively an inhabitant of North America in its wild state, and introduced domesticated into the old world at a compara-

tively recent period, the earlier naturalists supposed it to be a native of Africa and the East Indies, and its common name is said to have arisen from the belief that it originated in Turkey; it was carried to England in the early part of the 16th century by William Strickland, the lieutenant to Sebastian Cabot in the voyages of discovery which he performed under the patronage of Henry VII. Since that time it has been acclimated in most parts of the world, and wherever known its flesh is highly esteemed; though the domestic bird has, contrary to the usual rule, degenerated in size, flavor, and beauty, it is everywhere regarded both by civilized and savage nations as the most delicious of the poultry tribe; Christmas in Europe and Thanksgiving day in the northern and middle United States would be bereft of one of their most pleasant associations by the absence of a turkey at the family dinner; 300 years ago, the turkey furnished the usual Christmas fare of the English farmer's table; even the barbaric feasts of the South sea Islanders in honor of distinguished strangers are often rendered semi-civilized by the presence of this bird. The flesh of the wild turkey is more pleasant-like than that of the domesticated varieties. The old males keep by themselves, as do the females and young, the former being apt to destroy the eggs in order to prolong the honeymoon; they are polygamous, the males in the breeding season, in March, strutting before the females, with tail spread and elevated, wings drooping, feathers ruffled, head and neck drawn back, emitting a puffing sound; the males also utter singular notes, resembling the word "gobble" several times repeated, whence the name gobbler often applied to them; they fight desperately for the possession of the females. The nest is a slight hollow in the ground filled with withered leaves, in a dry and sheltered situation, and usually contains, when full, 10 to 15 eggs; after this time the males conceal themselves in order to recover their condition; the females alone incubate, carefully concealing the nest, approaching it with great caution and always in a different way, covering the eggs with dry leaves when going in search of food, and bravely defending them against crows and other depredators; sometimes 3 or 4 females lay in one nest, one remaining to guard it while the others seek for food; after the young are hatched the males are attentive to them; the young run as soon as hatched, but are very tender and easily killed by cold and wet; the female calls her young by a well known cluck. They run very fast, and when pursued trust more to their legs than to their wings for escape; they are generally shot from their roosts at night, or entrapped in a pen or enclosure into which they are enticed by grain; their feathers are employed by the Indians in ornamental work; their greatest enemies are lynxes and owls, and other carnivorous mammals and birds.—The Honduras or ocellated turkey (*M. ocellata*,

Ouv.), from Central America, is a much handsomer bird; the plumage is fine metallic green, passing to coppery, each of the tail feathers with 4 series of bluish green eye-like spots with copper-colored margin, and surrounded by a black ring; tail coverts tipped with white; there are only 14 tail feathers instead of 18, as in the preceding species. The Mexican turkey (*M. Mexicana*, Gould) resembles the domestic turkey more than does the *M. gallopavo*, in the white bars of the tail coverts and tail, but differs equally in the color and greater hairiness of the head and throat; it is of about the same size, the feathers of the sides of the body behind, the upper and under tail coverts, tipped with light brownish yellow or even whitish, and the rump with a greenish gloss; this is the *huacacoli* of the Mexicans.—All the turkeys have the feathers broad, distinct, and scale-like. According to J. Gould, the *M. gallopavo* is a native of Mexico and the original of our domestic species, the common wild turkey being another nearly allied species, which he calls *M. fera*; the habits in all are the same, and all are timid and stupid birds. According to Major Le Conte, the domestic differs in many points of structure and habits from the wild turkey, the former having an enormous dewlap from the base of the lower mandible to the caruncles on the lower part of the neck; the color of the naked skin is of a fleshy tint, becoming in the male fiery red in the breeding season from turpidity of the caruncles, and is less hairy; the tail and its coverts are always edged with whitish; the wild turkey has never been so domesticated as to breed in captivity, notwithstanding the many efforts to accomplish it; it will, however, cross with the domestic bird, the progeny being hardier and more prolific, whether the wild parent be the father or the mother; the color of the cooked flesh in the wild bird is much darker. The hypothesis is suggested in vol. ix. of the Pacific railroad reports that there are 4 species of turkey: 1, the *M. ocellata* (Ouv.), from Central America; 2, the *M. Americana* (Bartr.), the common wild turkey; 3, the *M. Mexicana* (Gould), of Mexico and the table lands of the Rocky mountains; and 4, the *M. gallopavo* (Linn.), the domestic turkey, perhaps derived from a species indigenous to the West Indies, transported as tame to Mexico and other parts of America, and taken to Europe in the early part of the 16th century, the wild originals having been exterminated by the natives, as were the dodo and solitaire in the islands of the Pacific; this would account for the fact that no wild species closely resembles the domesticated turkey. This requires no description; they are found of almost every shade of color, the gray or gray and white varieties being most esteemed; the white breeds grow to a large size, and have a pure and tender meat, but the black and brown mixed are the hardiest. Turkeys are not generally regarded as so profitable for the small farmer as hens; they require more stimu-

lating food to make them lay, and the young are easily killed by exposure to wet and extremes of heat and cold; they thrive best on high, dry, and sandy soil, and when grasshoppers are plentiful can pick up their own living; in temperate climates they generally lay twice a year, 15 eggs or less, white with small spots of reddish yellow. One male will suffice for 12 to 15 females, the latter being prolific for about 5 years, though those of 2 or 3 are the best hatchers; incubation lasts 27 or 28 days, and they are such close sitters that food must be placed within their reach; when they are raised on a large scale they are made to hatch in darkened places, and so that the turkey pouts, or young turkeys, shall all come out together; the young require warmth, shade, proper food, and pure water, and must be protected against rain and the hot sun; they are liable at all ages to many diseases, for the treatment of which special works in abundance can be consulted.

TURKEY (Turk. *Osmânî Vilâyeti*), or THE OTTOMAN EMPIRE, an empire comprising large tracts of contiguous territory in Europe, Asia, and Africa. This territory may properly be divided into the immediate and mediate possessions of the sultan, the former being under pashas or governors appointed directly by the Sublime Porte (as the government is called), and the latter acknowledging his suzerainty and paying tribute, but governed by their own officers, whose selection however, to be valid, must be approved by the sultan. Among the mediate possessions may be reckoned Wallachia, Moldavia, Servia, and Montenegro in Europe, a considerable portion of Arabia in Asia, and Egypt, Nubia, Kordofan, Tunis, Tripoli, and Fezzan in Africa. The immediate possessions of the Turkish empire are bounded by Austria, Servia, the Danubian principalities, Russia in Europe, the Black sea, the Russian Transcaucasian provinces, Persia, the Persian gulf, Arabia, the Mediterranean, the Archipelago, Greece, the Ionian sea, the Adriatic, and Montenegro. The area of the empire is variously estimated. Dr. A. Petermann (1858) gives it as follows: Turkey in Europe, 203,484 sq. m.; Turkey in Asia, 668,992; Turkey in Africa, 955,357; total, 1,827,784. Johnston, in the new edition of his "Physical Atlas" (1861): Turkey in Europe, 197,625 sq. m.; Turkey in Asia, 508,800; Turkey in Africa, 626,000; total, 1,332,425. The political divisions of the country are so arbitrary and so constantly changing, that it is almost impossible to give any satisfactory statement in regard to them. The territory is divided into *eyalets* or pashalics, the chief magistrate of which bears the title of *reis* or governor-general; the *eyalets* into *sandjaks* or *livas* (provinces), which are governed by *kaimakams* or lieutenant-governors; the *sandjaks* into *cazas* or districts; and the *cazas* into *nahiyas*, composed of villages and hamlets. According to the "Gotha Almanac" for 1862, the political divisions of the empire are as follows:

TURKEY IN EUROPE (15 eyalets, 48 sandjaks, and 276 cazas).

Eyalets or pachalics.	Capitals.
Adrianople (Thrace).....	Adrianople.
Bulgaria (eastern Bulgaria).....	Silistria.
Bucharest.....	Jassy.
Bulgaria (western Bulgaria).....	Bucharest.
Nissa.....	Widin.
Skopje (eastern Albania).....	Uskup.
Belgrade.....	Belgrade.
he fortress of Belgrade.....
Croatia (including Turkish Croatia and the Herzegovina).....	Bosna Serai.
Montenegro.....	Monastir.
Janina.....	Janina.
Salonica.....	Salonica.
Rhodes.....	Rhodes.
Candia.....	Candia.

TURKEY IN ASIA (23 eyalets, 78 sandjaks, and 858 cazas).

Eyalets.	Capitals.
Kastamuni (Paphlagonia).....	Kastamuni.
Broussa.....	Broussa.
Smyrna.....	Smyrna.
Konieh.....	Konieh.
Adana.....	Adana.
Yuzgat.....	Yuzgat.
Sivas.....	Sivas.
Trebisond.....	Trebisond.
Erzurum.....	Erzurum.
Van.....	Van.
Diarbekir.....	Diarbekir.
Kharpoat.....	Kharpoat.
Aleppo.....	Aleppo.
Beirut.....	Beirut.
Dair-el-Kamr.....	Dair-el-Kamr.
Damascus.....	Damascus.
Schehrzoz.....	Schehrzoz.
Bagdad.....	Bagdad.
Moscow.....	Moscow.
Jiddah.....	Jiddah.
Medina.....	Medina.
Mocha.....	Mocha.

TURKEY IN AFRICA (3 eyalets).

Eyalets.	Capitals.
Cairo.....	Cairo.
Tripoli.....	Tripoli.
Tunis.....	Tunis.

For African Turkey, see EGYPT, NUBIA, TRIPOLI, TUNIS, &c.) The largest cities of European Turkey are Constantinople, Adrianople, Salonica, Bucharest, and Sophia, all of them having over 50,000, and two over 100,000 inhabitants; besides which there are 22 towns having a population between 20,000 and 50,000, and 18 between 10,000 and 20,000. Asiatic Turkey has two cities, Smyrna and Damascus, with a population above 100,000; Scutari, Broussa, Afium, Aleppo, Kutaieh, Bagdad, and Bassorah have each over 50,000; 17 other towns have between 20,000 and 50,000, and 27 between 10,000 and 20,000. There has been no complete census of the Turkish empire since 1846, and its population is variously stated. Dr. Petermann estimated it in 1858 as follows: European Turkey, 15,500,000; Asiatic, 16,500,000; African, 5,050,000; total, 36,600,000. Keith Johnston in his "Physical Atlas" of 1861: European Turkey, 15,500,000; Asiatic, 16,050,000; African, 8,695,000; total, 40,245,000. Others still estimate the population of European Turkey at 16,440,000. The adherents to different religions among the inhabit-

ants of European and Asiatic Turkey were estimated as follows by Dr. Kolb in 1860:

Religion.	European Turkey.	Asiatic Turkey.	Total.
Muslimans.....	4,550,000	12,650,000	17,200,000
Greeks and Armenians.....	10,000,000	800,000	10,800,000
Roman Catholics.....	640,000	640,000
United Greeks and Armenians.....	100,000	100,000
Syrians and other minor sects.....	90,000	90,000
Maronites.....	140,000	140,000
Jews.....	70,000	80,000	150,000
Total.....	15,260,000	13,290,000	28,550,000

Beside these, there are the gypsies, the Druses, the Yezidia, the Metawalis, the Nestorians, and several other sects, numbering in all about 3,000,000.—Turkey in Europe has a coast line of upward of 1,800 m., of which about 200 are washed by the Adriatic, 100 by the Ionian sea, 600 by the Ægean, and 400 by the Black sea. The harbors on the Adriatic are poor, but many of the others are excellent. The coast line of Asiatic Turkey has not been accurately measured, but it cannot fall short of 8,000 m., embracing the Mediterranean (including the archipelago or Ægean sea) from the Dardanelles to the boundary of Egypt, the Black sea from the Bosphorus to St. Nicolai, and the sea of Marmora from the Dardanelles to Constantinople. African Turkey has a coast line on the Mediterranean from Cape Rosa to El Arian, and along the whole western side of the Red sea from Suez to Cape Bab-el-Mandeb. Arabia, which also may be reckoned as partly belonging to the empire, has the E. shore of the Red sea and the Persian gulf for its sea borders. This vast extent of coast embraces many of the best harbors in the world. It is indented by numerous gulfs and bays, of which the principal are the gulfs of Drin, Avlona, Arta, Salonica, Cassandra, Monte Santo, Enos, Saros, and Boorghas in Europe; Adramyti, Smyrna, Scala Nova, Cos, Makri, Adalia, Scanderoon, and the Persian gulf in Asia; and the gulfs of Sidra, Canea, and Suez in Africa. There are but few lakes in European Turkey, but in Turkey in Asia there are many of considerable size; the largest and best known are Lake Van in Armenia; Isnik, Abulhonte, Maniyas, Egerdir, Tuz, and Kereli in Asia Minor; Bahr-el-Merdj near Damascus; and Bahr-el-Huleh, the lake of Tiberias, and the Dead sea in Palestine. Most of these are salt, and have no outlet. The rivers of Turkey in Europe may be classed under 3 heads: those flowing respectively into the Adriatic and Ionian seas, into the Ægean, and into the Black sea. The first class are usually small, rising near the coast range of mountains; the Narrenta, Drin, and Voyutza are the principal. The second class are larger, the Salembria, Vardar, Karasu, Struma, and Maritza being the most important. In the last class, those flowing into the Black sea, are the Danube and many of its most important tributaries, especially the Pruth, Sereth, Jalomitza, Aluta, Isker, Shyl, Morava, and Save. The rivers of Asi-

* Partially independent.

atic Turkey may be arranged in 5 classes: those flowing into the Black sea, the Mediterranean, the Red sea, and the Persian gulf, and the Jordan with its tributaries, flowing into the Dead sea. The principal rivers flowing into the Black sea are the Tchoruk, Yeshil-Irmak, Kizil-Irmak, and Sakaria. Those discharging into the Mediterranean are mostly small, though some of them are connected with important events in ancient history; the most important are the Koduz, Mendere, Syhoon, Jyhoon, Nahr-el-Asi or Orontes, Kasimieh or Leontes, Mukutta or Kishon, and Aasuf or Kanah. The streams falling into the Red sea on its E. side are all small and unworthy of notice; but among those flowing into the Persian gulf are the Euphrates and Tigris with their numerous tributaries.—The greater part of the islands of the Grecian archipelago, and those of the sea of Marmora, as well as the larger islands of Orete or Candia, Rhodes, and Cyprus, belong to the Turkish empire.—There are 3 principal mountain ranges in European Turkey, which form the great watersheds between the different basins of the country; they are: 1. The Illyrio-Hellenic or western range, comprising the Dinaric Alps, a continuation of the Julian Alps, which separate the Adriatic coast from the basin of the Save, and having its culminating point in Mount Dinara, 7,458 feet high, and the Pindic chain, connected on the N. with the preceding, separating western Albania and Epirus from Macedonia and Thessaly, uniting with the Olympian chain on the S., and forming the watershed between the Ionian and *Ægean* seas; Mt. Ida in Candia seems to be a continuation of this chain. Its principal summits are Mts. Olympus, Metzovo, Ida, Ossa, Othrya, and Pelion. 2. The Balkan or Mt. Hæmus range, branching off from the preceding range N. E. of Albania, dividing Macedonia and Thrace from Bulgaria, and terminating in Cape Emineh on the Black sea. It consists of two main branches: the Balkan proper, which has 3 principal summits, the Great Balkan, the Emineh Dag, and the Tchan Dag; and the Despoto Dag chain in the W. of Thrace, whose chief summits are the Relo Dag and Mt. Athos, or Monte Santo. 3. The south-eastern Carpathians, forming the watershed between the Theiss and the lower Danube. This range lies mainly in Austria. The principal passes of these ranges are Trajan's gate and the Shumla pass in the Balkan; the Vulcan, Red Tower, Roman, Bodza, Oitoz, and Gyimes passes in the Carpathians, between Wallachia and Moldavia and Transylvania. The mountain system of Asiatic Turkey is composed of the two nearly parallel ranges, Taurus and Anti-Taurus, which form the connecting link between the Balkan and the mountain systems of Syria, Caucasus, and Persia; and the Lebanon range, proceeding southward from Taurus in the province of Marash, and extending parallel with the coast of Syria to Mt. Hermon in the north of Palestine, a summit rising above

10,000 feet, and thence at a lower elevation through Palestine to the Sinaitic peninsula, where it terminates on the shore of the Red sea.—The surface of European Turkey is undulating, and sometimes mountainous, but with a large proportion of arable land of moderate elevation. A considerable part of Asiatic Turkey consists of elevated plateaus, many of them scantily watered, while in other regions are very fertile, but consisting of steep and precipitous hills and narrow valleys, the sands of the desert have covered the soil and rendered the country barren. The plains are generally desert from want of irrigation; and though the slopes of the mountains afford fine pasturage, the frequent raids of Bedouins and Kurds materially diminish the amount of production. That part of European Turkey bounded by the Balkan, Mt. Pindus, and the basin of the Maritza, together with the N. part of the Dobrodja, and a tract S. of the gulf of Boorphas, is covered with primitive rocks; secondary strata occur in the western provinces, and N. of the Balkan from the Morava to the Black sea: the tertiary formations predominate throughout the basin of the Save and Maritza, and in the S. W. of Albania. There are several small tracts of the upper paleozoic N. W. of Constantinople, in the Balkan, and on the Danube near Orsova. The geology of Asiatic Turkey has been but imperfectly explored, but so far as known it corresponds to that of European Turkey, with perhaps less of the tertiary formations. The soil of European Turkey is for the most part very fertile, yielding large returns to the husbandman; but in past times the oppressive system of farming the taxes did much to prevent agricultural improvement, and the soil is tilled in the most primitive method. In Asiatic Turkey there is a deficiency of moisture, and many tracts once yielding most bountiful crops are now, from want of irrigation, reduced to the condition of sandy deserts. This is particularly the case with considerable districts of Palestine and other portions of Syria.—Turkey in Europe is subject to violent climatic changes. Owing to the elevation of considerable portions and to the cold N. E. winds from the interior of Russia, the winter is in many parts excessively cold, the thermometer descending in the plains of Wallachia and Moldavia to 15° below zero; and at the mouth of the Danube the winter temperature is the same as in the interior of Iceland. Around Constantinople the temperature of winter and spring is very variable, snow and hard frost alternating with mild weather, and a change of 30° in a single night is not uncommon. Albania, which is sheltered from the N. E. winds by mountains, has a more uniform climate, but is subject to earthquakes. In summer the rocky districts of the interior and the valleys of the W. which look seaward are insupportably hot. At Constantinople the mean temperature of the year is 56.3°, of the winter 40.3°, and of the summer 71.2°. The

average fall of rain for the year over the entire peninsula does not exceed 32 inches. The climate of Asiatic Turkey varies little from that of the European portion of the empire. It is cold and humid in the mountainous regions in the winter months, but in the sheltered valleys and plains it is warm and delightful. The summer heats are excessive, especially in the valleys. The valley of the Jordan and the tract watered by the Euphrates and Tigris are intolerably hot and dry in summer. Little or no rain falls from April to the middle of September, but the night dews are heavy. The peaks of Mt. Ararat and of the higher summits of the Lebanon and Taurus ranges are covered with perpetual snow. The mean annual temperature at Jerusalem is 62.6°, that of summer 78.8°, and that of winter 49.6°.—In European Turkey no coal has been found, but iron of the best quality is abundant. Argentiferous lead ore exists in considerable quantities; copper, sulphur, salt, alum, and a little gold are found. In Asiatic Turkey, there are copper, lead, alum, silver, rock salt, and mineral waters in Armenia; in Asia Minor, all these and considerable quantities of nitre; in Syria, iron, coal, and limestone, and west of the Jordan indurated chalk.—The chief botanical characteristic of both European and Asiatic Turkey is the predominance of the *labiate*, *caryophyllaceae*, *ericaceae* or heaths, of the evergreens belonging to the *conifera*, and of the amentaceous trees common to the south of Europe. In the basin of the Danube the pine, beech, oak, lime, and ash are the principal forest trees, and the apple, pear, cherry, and apricot the most common fruit trees. In the provinces S. of the Balkan these trees are only found on the slopes of the mountains, while on the lower lands the palm, maple, almond, sycamore, walnut, chestnut, and carob trees, and the box, myrtle, laurel, and other evergreens, are found; in Bosnia and Croatia there are large forests of fir and pine; the maritime plains of Albania are favorable to the growth of the olive, orange, citron, and vine, as well as to the peach, plum, and numerous other fruit trees; and the plain of Adrianople, as well as most of the region S. of the Balkan, abounds in roses, from which the attar is largely distilled. Of agricultural products, maize is cultivated in the south, rice, cotton, rye, and barley in the central provinces, and wheat, barley, and millet in the north. Though producing forest trees of the same families with those of European Turkey, the predominant trees of Asiatic Turkey are of different genera. The cedar, cypress, and evergreen oak crown the lower summits and thrive on the slopes of Lebanon and Taurus; the sycamore and mulberry occupy the lower hills, and the olive, fig, citron, orange, pomegranate, and vine flourish luxuriantly in the lowlands. Mesopotamia abounds in dates, and in wheat, barley, rice, maize, tobacco, hemp, flax, and cotton.—The wild animals of European Turkey are the wild boar, bear, badger, marten, wolf, wild dog, fox, civet, wild

cat, 22 species of bat, squirrel, beaver, hedgehog, mole, mouse, rat, several species of hare, the fallow deer, the roe, antelope, chamois, and wild ox. The lion, formerly an inhabitant of Mt. Olympus, is extirpated. Of birds 259 species have been counted, of which 31 are birds of prey, 100 songsters, 12 gallinaceous birds, 15 climbers, 64 waders, and 37 swimmers. Game is plentiful, especially in the mountains. Fish are numerous, embracing all the known species of the Mediterranean; tunny, coral, and sponge fisheries are extensively prosecuted; trout and other fish abound in the rivers, and the collection of leeches from the marshes is an important trade. In Asiatic Turkey, the lion is still found E. of the Euphrates; the striped hyæna, lynx, panther, buffalo, wild boar, and wild ass occur in Mesopotamia; the bear, wolf, wild hog, and jackal in Asia Minor; while the leopard, hedgehog, jerboa, hare, mole, and wolf are found throughout Syria, and the Syrian bear on Mt. Lebanon. The camel, dromedary, horse of the best breeds, ass, ox, sheep, and goat are the principal domestic animals. Of the two last there are several peculiar varieties. The Angora goat, celebrated for the fineness of its hair, and the broad-tailed sheep are specially noticeable. The birds, fishes, and reptiles differ little from those of Turkey in Europe.—Perhaps no country in the world is inhabited by so great a variety of races as the Turkish empire. The Turks are divided into two races: the Osmanlis, or Turks proper, the ruling race, whose numbers are estimated at about 3,000,000 in European and 10,500,000 in Asiatic Turkey; and the Toorkomans, who are principally found in northern Mesopotamia and adjoining districts, and do not probably exceed 100,000. The Greeks are about equally divided between the European and Asiatic divisions, and number in all somewhat more than 2,000,000. The Armenians are about 500,000 in European and 2,000,000 in Asiatic Turkey. The Slavic races, under which term are principally included the Bulgarians, Servians, Bosnians, Herzegovinians, and Montenegrins, number about 6,000,000, and are all in European Turkey. The Roumans or Wallachs, a Daco-Roman race, inhabiting chiefly the Danubian principalities, number about 4,000,000. Beside these there are upward of 1,000,000 Arnauts or Albanians proper in the province called after them; not far from 1,000,000 Arabs in Asiatic Turkey, and about 4,000,000 in the African Turkish possessions; about 240,000 Syrians, all in Asiatic Turkey; about 200,000 Jews, 90,000 Franks or western Christians, 1,000,000 or more Koords, 220,000 gypsies, 30,000 to 50,000 Druses, about the same number of Tartars, and large numbers of Circassians and other Caucasians; and in Africa, Copts, Nubians, Berbers, &c. The Osmanlis are in general a robust, well formed race, with a grave and commanding countenance. They are intelligent and capable of readily acquiring knowledge, generally courteous and hospitable to stran-

gers, constant in their friendships, but given to dissimulation, indolent, bigoted, licentious, and deficient in tender emotions. They are almost universally fatalists. The Osmanli is too indolent to engage willingly in severe labor. He is exempted from the capitation tax which the other races are compelled to pay; he sometimes condescends to engage in trade, though no match for the sharp Greek or the wily Armenian, but, unless in a very abject condition, avoids agricultural or mechanical pursuits. The Toorkomans and Koords are shepherds and herdsmen, often migratory, but sometimes occupying villages and cultivating the soil. They are more industrious than the Osmanlis. The Slavic races, the Roumans, and the Albanians are the principal agriculturists in European, and the Armenians, Syrians, and Druses, with some of the Osmanlis, in Asiatic Turkey.—Agriculture is in a low state, and the implements and culture are of the rudest description, the former being almost universally of the same form as those in use 3,000 years ago. Notwithstanding this imperfect cultivation, the crops of grain, rice, cotton, tobacco, &c., owing to the fertility of the soil, are very large, yielding from 25 to 100 fold return. The olive is largely cultivated for food and for oil, and the grape, fig, date, orange, and citron yield abundant and profitable returns. The manufactures of the Turkish empire are comparatively few and simple. Wax, raisins, dried figs, fig paste, olive oil, silks, red cloth, goat-skin morocco of excellent quality, saddlery, swords of superior workmanship, firearms, copper and tin utensils, shawls, carpets, dye stuffs, embroidery, essential oils, attar of roses, brandy from prunes, &c., are the principal. Its commerce is extensive and on the increase. The exports are principally raw materials, silk, cotton, tobacco, wheat, maize, wool, goats' hair, meerschaum clay, wax, honey, and sponges; drugs and dye stuffs, opium, madder, gall nuts, gum arabic, valonia, and various gum resins; figs, currants, raisins, wines, olive oil, &c., with some carpets and red cloths. The imports are manufactured goods of all kinds, glass, pottery, arms, paper, cutlery, steel, amber, &c. The value of the entire imports of the empire cannot be ascertained, but in 1860 there were imported into the 3 ports of Constantinople, Smyrna, and Trebizond foreign goods to the value of \$75,502,817. The exports are much less. Of this trade Great Britain has the largest share, exporting to Turkey in 1858 about \$50,000,000 worth, and receiving from that country about \$39,000,000. In 1847 the imports from Great Britain at Constantinople and Smyrna alone exceeded \$47,000,000. The exports from Turkey to the United States in 1860 were \$1,041,959, and the imports about \$420,000. With the exception of a few of the great thoroughfares, there are really no roads worthy of the name throughout the empire. Two railways have recently been constructed (1862), one from Smyrna to Aidin, to be completed to

the promontory opposite Samos, and the other from Rassova on the Danube to Kustendji on the Black sea. Several others have been projected. The Danube with its navigable tributaries forms the great channel of commerce for the northern provinces of European Turkey.—Education has been hitherto very greatly neglected, but there is now a deep interest taken in intellectual culture, since it is the only avenue to many kinds of employment. In 1847 the system of public instruction was entirely remodelled. There are now elementary schools for reading, writing, arithmetic, and religious instruction; middle schools, in which Arabic composition and Mohammedan religious history are taught; and colleges for higher branches, such as medicine, agriculture, and naval and military science. The instruction in these is gratuitous, and parents are required to send their children to school on attaining the age of 6 years. Wealthy Osmanlis often send their children to Paris to be educated. The Christian (Greek, Roman Catholic, and Armenian) sects have some schools of their own, but there is very little thorough education in the empire. There are now 4 newspapers in the Turkish language, 2 in Greek, 2 in French, and one each in English, Armenian, Bulgarian, Arabic, and Hebrew, beside several Rouman and Servian newspapers published in the tributary provinces. The state religion is the Mohammedan, but Christian, Jewish, and other sects are recognized, and permitted to conduct their worship in their own way. Previous to 1836 a Mohammedan who became a Christian or Jew, if of Turkish birth, was liable to be put to death; but by a *hatti-sherif* or decree of that year the sultan abolished this penalty, and gave all persons of whatever birth equal rights and justice, and liberty to embrace whatever religion they chose. This *hatti-sherif*, or *hatti-humayum* as it is sometimes called, has been strictly enforced in those pashalics under the immediate government of the sultan, but in the remoter provinces and among the more bigoted Mohammedans it has remained virtually a dead letter.—The government of Turkey is a pure despotism, or absolute monarchy. The emperor has the titles of sultan, padishah, grand seignor, khan, and hunkiar. Though professedly absolute, his power is practically very much limited by the sheik ul-Islam, who is at the head of the combined religious and judicial order of the nation called the chain of the ulema, composed of the ministers of religion and justice, and has the right of objecting to any decree of the sultan. The first executive officer of the government is the grand vizier, who is the vicerent of the sovereign, and is usually called *sadr-i aam* (great president). The other officers composing the cabinet or divan are the presidents of the supreme council of state (the *ak-biamsi adlis*) and the grand council of internal affairs (the *tansimat*); the *seraskier*, who is commander-in-chief and minister of war; the *capudan pasha*, or high admiral; the *mullis*

asiri, or minister of finance; the *kharidshahi asiri* (formerly *reis effendi*), the minister for foreign affairs; the *marif nasiri*, or minister of public instruction; the *sarbhani mushiri*, master of the mint; the *tidjaret nasiri*, or minister of commerce; the *daava nasiri*, or minister of justice; the *efkaf nasiri*, administrator of mosque property and charitable trusts; and the *sabti shahi mushiri*, or minister of police. The governors-general (*valis*) of the *eyalets* or pashalics receive a salary of \$3,000 per month, and the *aimakams* or governors of *sandjaks* less sums according to their rank. The fixed revenues of the pashalics are not now farmed out as formerly, but are collected through *defterdars* or receivers-general in each pashalic, in the same way as in other civilized countries. The variable imposts are farmed, but the power of the farmers to oppress those from whom the impost is to be collected is much restricted. The *ushirs* and *kaimakams* are appointed by the sultan on the nomination of the sultan, and are removable at the sultan's pleasure. They no longer possess the power of life and death. The Koran being the supreme authority in law as well as religion, the law officers, who must all be Osmanlis, form a part of the chain of the *ulema*, and receive the same training as the ministers of religion; they rise through 10 degrees, from that of *imam* to that of *grand mufti*. The receipts of the imperial treasury, for the year ending Oct. 1861, were \$57,220,000, and the government expenditure for the same period \$67,045,000. The public debt, Sept. 18, 1861, was of two classes: the home debt, amounting to \$92,392,000, and the foreign debt, of \$165,762,000. The interest on this debt absorbs 16 per cent. of the annual revenue. The army of the empire is divided into the *istim* or permanent force, and the *radif* or reserve. The effective or permanent force is nominally 180,000 men, but really does not exceed 20,000, divided into 6 army corps (*ordus*), each under the command of a *mushir* or field marshal, who must be a *ferik pasha*, or of equal rank with the governor of an *eyalet*. These corps are severally composed of 2 divisions, having each 3 regiments of infantry, 2 of cavalry, and of artillery. The reserve is also composed of 6 corps, each commanded by a *marhal* of the rank of a *liva pasha*, or governor of a *liva* or *sandjak*. The number of men enrolled in the reserve is variously stated at from 126,000 to 200,000. Beside these there are 4 detached divisions: the army of Candia, of 1,000 men; the army of Tripoli, 5,000; that of Tunis, 5,000; and the central division of artillery, comprising about 80,000. Bosnia and Albania, in case of invasion, are bound to furnish each 80,000 men, Servia 40,000, and Egypt 18,000, making in all 138,000 levies from these states. The navy consists nominally of 8 ships of the line, 12 frigates, 1 corvettes, 8 brigs, 9 schooners, and 23 steamers. Of these, 18 steamers, 2 ships of the line, 5 frigates, 6 corvettes, and 5 brigs, carrying in all 1,218 cannon, and having 84,000 marines and

sailors, are fit for effective service.—The Turkish empire in Europe dates only from the overthrow of the Byzantine empire in the 15th century; but the Osmanlis had already become a formidable power, and the masters of the greater part of Asiatic Turkey, in the early years of the 14th century. (See TURKEY.) In 1299 Othman or Osman (from whom are derived the names Ottoman and Osmanli) invaded Bithynia, and occupied the territory of Nicæa. In 1296 his son Orchan took Prusa (Broussa), the capital of Bithynia, and subsequently penetrated into Thrace. His son Murad or Amurath I. subdued the whole of Thrace, in 1362 established from his young captives the military band known as janizaries, and subsequently conquered the Bulgarians, Servians, Bosnians, and Albanians, and fell on the battle field of Kossovo in 1389. He was succeeded by his son Bajazet or Bayazid, surnamed Ilderim (the lightning), who completed the conquest of Asia Minor, of a portion of Thrace which had revolted, and of Macedonia and Thessaly, overran central Greece, and conquered in the great battle of Nicopolis, but was defeated and taken prisoner by Tamerlane in 1402. In 1422 the sons of Bajazet, who had contended with each other for the government, which they had wrested from Tamerlane's successors, had all deceased, and Amurath II., the grandson of Bajazet, succeeded to an undivided empire, which he greatly increased by the recapture of Adrianople, and the reduction of Roumelia, Servia, Albania, and the whole of Greece north of the isthmus. For a time Scanderbeg, the Albanian chief, and Hunyady, the waywode of Transylvania, were successful in checking his conquests; but the severe defeat of Ladislas, king of Hungary and Poland, at Varna (1444), effectually destroyed the hopes of the Christian world. Amurath II. was succeeded in 1451 by Mohammed II., who in 1458 took Constantinople, and established the Osmanli throne on the ruins of the palace of the Roman emperors. He next attempted the siege of Belgrade, but was repulsed with heavy loss by Hunyady, and, turning his attention to Greece, reduced the whole Morea to subjection; he subsequently reduced Trebizond, and in 1466, having driven Scanderbeg into Lissa, then belonging to the Venetians, reigned supreme over all the eastern provinces of the Roman empire in Europe, and the whole of Asia Minor. His grandson Selim I. (1512–20), the son of Bajazet II., was victorious over the Persians, and reduced Kooristan, Syria, Egypt, and a part of Arabia. His son, Solyman the Magnificent (1520–'66), made conquests on every side, successively reducing Belgrade and the island of Rhodes, Hungary, Armenia, Irak, Tunis and Algiers, Croatia, Yemen, Shirvan, Georgia, and Transylvania. Moldavia was made tributary. Selim II., his son, conquered Cyprus, but lost the great naval battle of Lepanto (1571). From that time a weaker race of princes succeeded to the throne, and the janizaries gained a degree of power which

made them for the most part the actual rulers of the country. (For the reigns of the most important sultans of this period, see AMURATH III. and IV., MOHAMMED IV., ACHMET III., MAHMOUD I., and ABDUL HAMET.) Frequent wars with Poland, Austria, Persia, Venice, and Russia were waged, mostly under the lead of the grand viziers, and but rarely with success. Montecuculi, Sobieski, Louis of Baden, and Prince Eugene destroyed the Turkish power on the Danube; and at the peace of Carlowitz in 1699 Mustapha II. surrendered almost all the Hungarian provinces to Austria, Azof to Peter the Great of Russia, Podolia and Ukraine to Poland, and the Morea and Dalmatia to Venice. During almost the whole of the 18th century Turkey was at war, with brief intervals of peace or truce, with Russia, and much of the time with Austria also. Though occasionally successful, this protracted warfare was on the whole exceedingly disastrous to Turkey, causing her the loss of the Crimea and all her possessions N. of the Black sea, and of the exclusive navigation of that sea and the straits connected with it. In other quarters, too, losses were suffered. The reign of Selim III. (1789 to 1807), though characterized by enlightened reforms and great ability, was one in which disaster still followed the empire. By the peace of Jassy (1792) the Dniester was made the frontier between Russia and Turkey. Several of the pashas aspired to independence, and the conquest of Egypt by Bonaparte led to a war with France, which ended in considerable concessions to that power; and wars with Russia and England and the rebellion of the janizaries made the condition of Turkey more perilous than ever before. Selim was deposed in 1807, at the instance of the janizaries and the grand mufti, in consequence of the reforms he had introduced. The one year's reign of Mustapha IV., who restored the ancient régime, was followed in 1808 by the vigorous administration of Mahmoud II. Introducing more radical reforms than any of his predecessors, concluding peace with England in 1809 and Russia in 1812, not without considerable sacrifice of territory, and ridding himself by a terrible slaughter of the janizaries, he was in a position to rule successfully and with advantage to his empire; but the revolution of the Greeks and the insurrection of Mehemet Ali in Egypt involved him in new and still greater difficulties. Greece achieved her independence at an almost fatal cost to Turkey. The revolted pasha of Egypt had also substantially attained to an independent position, when in 1840 the great powers of Europe, with the exception of France, deeming the adherence of Egypt to Turkey necessary to the maintenance of the balance of power in Europe, reduced him to the condition of a tributary. On the death of Mahmoud in 1839, his son Abdul Medjid, then but 16 years of age, ascended the throne. In July, 1841, the great powers of Europe guaranteed the integrity of the Turkish empire, the result of which was the consolidation and

strengthening of the empire, and the suppression of most of the chronic difficulties and revolts which had so long impaired the efficiency of its government. The revolutions of 1848 did not disturb Turkey, except in the principalities of Wallachia and Moldavia, which were tributaries rather than provinces. The sultan introduced numerous reforms; among others the decree known as the *hatti-sherif* already referred to, first promulgated in 1839, and confirmed at the close of the Crimean war in 1856. The claims of the czar Nicholas to a protectorate over the Christian subjects of the sultan led to a declaration of war against Russia in Oct. 1853, in which England, France, and Sardinia subsequently joined. (See CREMIA.) As a result of this war, in the early part of which the Turkish forces under Omer Pasha distinguished themselves, the access to the mouth of the Danube and the territory around it were ceded to Turkey, and Russia was forbidden to maintain any considerable fleet in the Black sea, or to attempt the exercise of authority over the subjects of the Porte. The Crimean war was followed, as it was preceded, by considerable troubles with the small semi-independent state of Montenegro. In June, 1858, fanatic Mohammedans at Jiddah massacred the British and French consuls; the town was bombarded by a British man-of-war, and subsequently a part of the criminals were discovered and executed. In Sept. 1859, a conspiracy was discovered, having for its purpose the assassination of the sultan and his principal ministers and the restoration of the ancient customs; the principal movers in it were arrested and condemned to perpetual imprisonment in a fortress. In June, 1860, a war broke out between the Druses and Maronites in Syria, and many thousands of both races were massacred. The interposition of France and England led to the adoption of rigorous measures for its suppression, which was accomplished in the autumn of the same year. On June 25, 1861, Abdul Medjid died, and was succeeded by his brother Abdul Aziz, who has commenced a decided retrenchment of the expenses of the government, and gives promise of being a more efficient ruler than his predecessor. This new reign, however, is already troubled by a renewed conflict with Montenegro, which on the part of the Turks is carried on, with varying success, under the command of Omer Pasha.

TURKEY BUZZARD, the popular name of one of the common American vultures, *cathartes aura* (Illig.). It is about 2½ feet long and 6 in extent of wings; the bill, as in the other species of the genus (which includes the black vulture or carrion crow and the great California vulture), is long and comparatively slender, with an arched, strong tip; a large soft cere. 1 of the length of the bill, in which the pervious nostrils are placed; wings long and pointed, the 8d and 4th quills nearly equal and longest; tail moderate and nearly even; tarsi short, plumed below the knee, and with small scales:

oes weak, united by a small membrane, hind one short and weak, and claws strong; head and neck naked, no fleshy crest, and the plumage black. All the vultures which have the nostrils perforated belong to the new world; this genus is one of the sub-family *sarcoramphæ* or condors. The color is brownish black, with a purplish lustre, darkest on the back and upper part of tail, and some pale edgings; bill yellowish; head and neck bright red, with a few scattered hair-like feathers and wrinkled skin; plumage commencing on the neck with a circular ruff of prominent feathers. It is found all over North America, except the arctic regions, going on the Pacific coast as far N. as the British possessions, but on the Atlantic rarely seen N. of New Jersey; but it is most abundant in the southern states, migrating thither from the colder parts. It is essentially a carrion eater, though it will devour any kind of fresh meat, and even small living mammals, birds, and reptiles; it has been known to attack and kill weak and sickly animals in the fields. It associates in flocks of 25 to 30, even when not feeding, becoming very familiar in the southern cities, where it performs a very useful scavenger's work in devouring any carrion or animal filth left in the streets; it is called John Crow vulture in Jamaica, and gallinazo in many places in the S. W. portions of North America. It finds out its prey at a great distance by the acute sense of sight, like other vultures; its flight is lofty, and uncommonly graceful and long sustained, sailing for miles without apparent effort, with the tips of the wings bent upward by the weight of the body; it is often seen in company with the black vulture, hawks, kites, and crows; it is also a good walker on the ground. Its average weight is $1\frac{1}{2}$ lbs., which is somewhat less than that of the black vulture; it is also less common than the latter bird, more retired in its habits, and, though more inclined to carrion, neater, better formed, and a more rapid and elegant flier. It is fond of particular roosting places, generally high and dead cypresses in deep swamps; it drinks freely, immersing the bill to the base and taking long draughts; it is very sensitive to cold, and liable to disease about the eyes and legs in the shape of warts and excrescences; when alarmed or provoked it utters a loud hissing noise. In the southern states the breeding season begins early in February, the nest being usually placed in the hollow of a dead tree, or, it is said, even on the ground, and containing 2 eggs, $2\frac{1}{2}$ by 2 inches, light cream-colored, with irregular black and brown marks; both birds incubate, each feeding the other and the young with the disgorged contents of the stomach; incubation lasts 82 days, and only one brood is raised in a season; the nests become extremely dirty and fetid.

TURKISH LANGUAGE AND LITERATURE. The languages spoken by the different tribes of Turkish or Tartar origin form a principal division of the great Scythian, Altaic, or

Turanian family, of which the chief common characteristics have been pointed out under **TURANIAN RACE AND LANGUAGES**. They constitute together a well marked group of nearly related idioms; even the Yakoot—the one which differs most from the rest, and is supposed to have severed itself from the main stem before the division of the latter into its other branches—is so distinctly a Turkish language that its relationship is apparent upon the most superficial examination; and it has been asserted, although doubtless without good reason, that a Yakoot from the Lena could make himself passably understood at Constantinople. The Tartar dialects are for the most part known only by scanty vocabularies and the descriptions of travellers; a few have been treated grammatically; three or four, as the Uigur, the Jagatai or oriental Turkish, and the Osmanli, have received literary culture, and are to be studied in written monuments. Of these last, the dialect of the tribe which has been during the past 500 years dominant in European and Asiatic Turkey, or the Osmanli Turkish, as it is distinctively called, is of by far the greatest importance, and to it we shall chiefly direct our attention. Its peculiarities are such as naturally result from its position and its culture under the powerful influence of Arabic and Persian; every part of its vocabulary, and even some departments of its grammar, are filled with Arabic and Persian elements; so that it presents the remarkable and unique spectacle of a dialect made up of materials derived from the three grand and totally disconnected families of language, the Turanian, Semitic, and Indo-European, to the detriment, of course, of its native character, by the corruption of its forms and the artificiality of its style. This is true especially, however, of the language which is taught in the grammars and written in the literature; the vernacular idiom of the people is a much purer Turkish. The Osmanli is usually written with the Arabic alphabet, which is exceedingly ill suited to it, as to the Persian, since it marks the vowels very imperfectly, and in its distinction of consonantal sounds is in part defective and in part redundant; to construct the spoken alphabet and phonetic form of the language from the published grammars is well nigh an impossibility. It is also sometimes written with the Armenian alphabet, which represents it much more faithfully. It has 9 vowels: 4 hard, viz., *a*, *o*, *u*, and a peculiar guttural *i*; and 5 soft, viz., *ä* (*a* flat), *e*, *i*, *ö* (French *eu*), and *ü* (French *u*). In the same word, as a general rule, only vowels of one or of the other of these classes are allowed to succeed one another; the dominant syllable, which is usually the final one of the root or theme, assimilating to its own character all that follow it. The consonants are *y*, *r*, *l*; *ng*, *n*, *m*; *ç*, *çh*, *zh*; *kh*, *gh*, *f*, *v*; *k*, *g*, *t*, *d*, *p*, *b*; *h*; and the compounds *ch*, *j*. The language has no proper articles, although its numeral "one" and its demonstrative are sometimes

used nearly as articles. The adjective is uninflected. The nouns have no distinction of gender; their plural is formed by the addition of *lar* or *ler*. There is no nominative case-ending; the unchanged theme is employed as subject, in address (vocative), and also as indefinite object of a verb. Of cases, formed by inseparable affixed particles, which may properly be regarded as terminations of declension, there are an accusative, in *i*; a genitive, in *ung*; a dative, in *e*; an ablative, in *den*; an instrumental, in *le*; and a locative, in *de*. These suffixes are, saving certain slight euphonic changes, invariable; they are appended to the simple theme in the singular, and to the plural sign *ler* in the plural. The numerals are: 1, *bir*; 2, *iki*; 3, *üç*; 4, *dört*; 5, *beş*; 6, *altı*; 7, *yedi*; 8, *sekiz*; 9, *dokuz*; 10, *on*; 11, *on bir*, &c.; 20, *yegirmi*; 30, *otuz*; 40, *kırk*; 50, *elli*; 60, *altmış*; 70, *yetmiş*; 80, *sekse*; 90, *doksan*; 100, *yüz*; 1000, *bin*. To form the ordinals, *ıncı* is added. The personal pronouns, which alone offer some anomalies of declension, are: I, *ben*; we, *biz*; thou, *sen*; ye, *siz*. In the third person we have rather a demonstrative than a personal pronoun: that one, *o*; those, *onlar*. Possessive pronominal suffixes are: *m*, my; *nis*, our; *n*, thy; *nis*, your; *i* or *si*, his, hers, its; *ları* or *leri*, their. These are appended directly to the nominal theme, singular or plural, and the affixes of case follow them, as *baba-lar-um-dan*, from my fathers. There is no relative pronoun, except the Persian *ki*. The verbal roots are not always reducible to a monosyllabic form. From each root are formed a number of themes of derivative conjugation, by adding conjugational affixes; these are, for the passive, *ıl*; for the reflexive, *ın*; for the reciprocal, *ış*; for the causal, *der*; and for the negative, *me*; which last, by prefixing *a*, becomes a sign of impossibility. Any or all of these affixes may be combined at once with a verbal root, so far as the idea admits of their combined modification; so that in theory we may have as many as 36 themes from one root, each conjugated throughout in the same manner as the simple root: *e. g.*, from *sev-mek*, to love (*mek* is infinitive affix), come *sev-il-me-mek*, not to be loved; *sev-der-il-mek*, to be made to love; *sev-ış-il-me-mek*, not to be able to be loved by one another, &c. The root of the verb, without affix, is the 2d person singular imperative: *e. g.*, *sev*, love! The tenses and moods are of two kinds, simple and periphrastic. The former are formed either by appending a predicative pronominal suffix to a participle (except in the 3d person, which is left without suffix), or by adding a possessive suffix to a noun of action; thus, from *dogmak*, to strike: pres. part. *dogur*, striking; pres. *dogur-um*, striking-I, *i. e.*, I am striking, I strike; pret. *dogd-um*, striking-mine, *i. e.*, I have struck. The periphrastic tenses are formed by combining a participle or noun of action with an auxiliary verb; as *dogmuş idum*, having struck was I,

i. e., I had struck. By these means, a great variety of more or less genuine verbal forms is produced, in the admission and classification of which, however, grammarians greatly differ; and the verbal paradigm is a very rich one as regards the number and nicety of its distinctions. The prepositions in Turkish are all postpositive affixes; many proper prepositions, however, are borrowed by it from the Arabic and Persian, and are placed and construed according to the usage of those languages. It is almost entirely destitute of any conjunctions except those of Arabic and Persian origin, some of which—as those for and, but, or, if, &c.—are in frequent and familiar use, although more in the formal and written style than in the conversational. The place of conjunctions is supplied by gerundives and possessive forms, through means of which the different members of a compound sentence are twined into one, with the principal verb always at the end. This position of the verb, together with the operation of the rule that the determining word must precede the determined, gives the Turkish construction an inverted form which often seems very strange to our apprehension.—LITERATURE. The earliest literature produced by any of the divisions of the Turkish race is that of the Uigurs, a remote eastern branch of the family, who originally occupied the country south of Lake Baikal, but later established themselves about the Tangnu Tagh, and played a conspicuous part in the contests and migrations of central Asia during several centuries, until their nationality was swallowed up in the Mongol empire, about A. D. 1200. Something of culture and Christianity was communicated to them from Syria, doubtless by Nestorian missionaries; and their scanty alphabet, of 14 characters, formed from the Syriac, became later the parent of the Mongol and Manichæan alphabets. Most of the Uigur literature is lost, and of what remains only few relics have found their way to Europe; little is known of it in detail, although it has been made to yield some information respecting the history of the people. They are said by the Chinese to have received and translated the Chinese classics and histories, and they are known also to have adopted to some extent the Buddhist doctrines and literature. The second era of Turkish culture dates from the conquest by Turkish tribes of the countries of Mohammedan Asia, beginning with the latter half of the 10th century. Overrunning first the north-eastern provinces of Iran, and finding there the new Persian literature commencing its career, their wild chiefs became its admirers, patrons, and imitators, and the Turkish mind and language received that strong Persian impress which they have ever since borne. The eastern Turkish literature, or that produced beyond the Caspian, is usually called the Jagataian, from the name given to that country in the partition of the Mongol empire. It is much less abundant, and also much less known, than the literature

of the western branch. Its most flourishing period was from the time of Tamerlane (1400) to that of Baber (died 1530). Its most admired author is Mir Ali Shir, the vizier of Sultan Hussein, and a munificent patron of Persian authors, particularly of the poet Jami; his most interesting work, perhaps, is his collection of biographies of earlier Jagataian poets, with specimens of their productions. Of prime importance also are the memoirs of his own life and times by Sultan Baber, the conqueror of Hindostan and founder of the Mongol dynasty which has only just become finally extinct; they cover a period of nearly 40 years, and are written with entire simplicity and naturalness. The astronomical works prepared at Samarkand, under the patronage and direction of Ulugh Beg (died 1449), grandson of Tamerlane, deserve honorable notice.—The literature of the western, or Osmanli Turks, to which alone we usually apply the name of Turkish literature, is exceedingly rich, but it is, upon the whole, of inferior interest, because it contains so little that is original and distinctively national in style and spirit. It is mainly an imitation, more or less successful, of Persian models; or, in part, of Arabic also. As the language of the Osmanlis is crowded full of Persian words, compounds, phrases, forms of construction even, so is their history, their philosophy, their poetry, a re-working of Persian material, an echo of Persian taste. The history of the Osmanli literature commences with that of Osmanli nationality; even before the power of the dynasty was established by the capture of Constantinople, works had been produced which the nation has never let perish, and has hardly excelled; prominent among the great names of this era are those of Sheikhî, the romantic poet, and also the ablest physician of his time, of Solyman Ochelebi, of Nesimi the free-thinker, &c. But the most flourishing period in the whole history of the literature was the following century, the 16th, chiefly during the reigns of Solyman the Magnificent and his son Selim. Early in the century wrote Meshîhi, renowned as an elegiast, and Kemal Pasha Zadeh, a man of universal learning, and an admired author in many different departments, especially in history and in Moslem jurisprudence. Both these branches are of great importance and prominence in the Turkish literature. The latter of them—of inferior interest to us, but of the highest consequence to the Turks themselves, in its double aspect, religious and legal, and also indispensable to those who would fully understand the internal life of the nation—is illustrated by an unbroken series of great writers. In history, beside general and independent authors, such as Mohammed Effendi, Bechevi, Haji Khalfah, &c., deserve especial notice the line of official historiographers and annalists of the realm, commencing with Saad-ed-Deen; among his successors may be particularly mentioned Naima, Reshid, Izzi, and Vasif. Notwithstanding the turgid and affected style of

the official historians, they are most valuable authorities for the history of the Ottoman empire, in its internal and its external relations. Saad-ed-Deen wrote under Solyman, and has been excelled by none who came after him in dignity and philosophic spirit; he brought the story of the rise and growth of the Turkish power down to 1526. Of the same period is Lami'i, one of the most highly esteemed of Turkish authors, and in some departments quite unsurpassed. His works are of varied character, in both prose and verse, and include many translations from the Persian. Fasli, distinguished by depth of thought and tenderness of sentiment, lived till 1563. But the chief ornament of the century is Baki, the acknowledged prince of Turkish lyric poets, and ranked by the orientals with the Persian Hafiz and the Arab Motanebbi in the trio of unrivalled masters of song. He died at a great age in 1600. A new period of literary activity and excellence, although decidedly inferior to that already referred to, followed in the 17th century, under the patronage of the great vizier Köprülü, in the reign of Mohammed IV. Most worthy of note here are Nebî, the most admired poet of the century, Nefî, the first of Turkish satirists, Naima the historian, and Haji Khalfah, the historian, geographer, biographer, and encyclopædist, a man of immense learning and industry, whose history of Arabic, Persian, and Turkish literature, in Arabic, is a chief authority upon its subject, for both the East and the West. In the 18th century, the distinguished vizier Raghib Pasha is eminent both as an author and as a patron of learning; but among the innumerable writers, in every department, of the last century or two, there are few who deserve to be particularly noticed; we may mention merely Said Rufet Effendi, Aini Effendi, and Pertev Effendi as the most esteemed poets. The Turks have done little for the grammatical and lexicographical illustration of their own language, but, on the other hand, a great deal for that of the Arabic and Persian. The press was introduced into Constantinople early in the 18th century, by Ibrahim Effendi, and, both there and elsewhere, has been actively engaged in publishing the most important works in Arabic, Persian, and Turkish, especially the latter (including the series of official histories), together with hosts of less valuable or altogether insignificant productions. Many translations have been made by the Turks of European as well as oriental works.—The most accessible and useful helps to the study of Turkish are, of grammars, those of Davids (London, 1832) and Redhouse (in French, Paris, 1846); Kazem-Beg's grammar (in Russian; but in German by Zenker, Leipsic, 1848) includes also the other dialects, and is valuable for the comparative study of the language; Böhlingk's Yakoot grammar (in German, St. Petersburg, 1851) is also important in this bearing. Of chrestomathies, we have one by Dieterici (in French, Berlin, 1854), and Bar-

ker's reading book, grammar, and vocabulary (London, 1854). The best dictionaries are those of Kieffer and Bianchi (2d edition, Paris, 1849-'6, Turkish-French), and Redhouse (London, 1856-'7); a new and more complete one, by Zenker, explained in French and German, is now (1862) upon the point of appearing. See also Max Müller, "Science of Language" (London and New York, 1862).

TURKS, one of the most important branches of the Turanian family, for an account of whose linguistic and ethnological affinities the reader is referred to the articles on the **TURANIAN RACE AND LANGUAGES**, and **TURKISH LANGUAGE AND LITERATURE**. In former ethnological classifications they were sometimes set down as a Caucasian race, and in physical characteristics some of their tribes are nearly or quite what has been termed Caucasian; but more recent science shows that with the Indo-European family they have no connection. The first traces we find of them are as dwellers upon the northern slopes of the Altai range and along the valleys of the Tang-nu mountains, between the Irtysh and Yenisei rivers, on the confines of Siberia and China. From this region a portion of them emigrated S. W. into the country now known as Independent Toorkistan, occupying the valleys of the Jaxartes and Oxus; another party, taking a S. S. E. course, passed beyond the Altai, crossed the great desert and the Thian-shan mountains, and established themselves in the vicinity of Koko-nor and around the waters of the Hoang-ho. Here they led a nomadic life, following the course of the rivers which afforded pasturage to their flocks and herds, and depending upon these and the resources of the chase for a subsistence. A small number of their tribes preferred a permanent settlement, and engaged in agricultural pursuits; but the great body were for ages nomads, and by their frequent excursions for plunder into the Chinese towns and villages became the terror of that industrious but timid race. This branch of the Turkish family, occupying N. W. China, were called by the Chinese Hiong-nu ("vile slaves"), but proved too powerful for them for several centuries; and their empire in the 2d century B. C. extended, it is said, from the sea of Japan to the Volga, and embraced the whole of central Asia and a considerable portion of Siberia. They intermarried with the imperial family of China, and held the Chinese nation as vassals. At length, near the commencement of the Christian era, the Chinese emperor, by the aid of barbarian allies, defeated the Hiong-nu, and by encouraging divisions between their tribes contributed to their final overthrow. In A. D. 90 that portion of the Hiong-nu empire occupying the region S. of the Altai united with the Chinese in a war upon the northern portion, which resulted in their expulsion from the territory they had hitherto occupied, and their return to their former home in Independent Toorkistan. Before the commencement of the Christian era, a tribe of

Turks had wandered westward as far as the Don; they are mentioned by Pliny under the name of Turcae, and by Pomponius Mela under that of Iurcae; while other tribes had not long after penetrated into the mountainous regions of Asia Minor. In the 4th and 5th centuries of the Christian era, a portion of the Turks who had remained in the N. W. of China succeeded in conquering two provinces of that country, which they organized as independent kingdoms, to which the Chinese give the names of Tchao and Northern Liang; but the greater part of those who were driven out in the 8d century rallied around Lake Balkash, and after the 5th century made no further separate appearance in history. In the early part of the 6th century a new Turkish empire, apparently having its nucleus in what is now Independent Toorkistan and Soongaria, threatened the peace of Asia. They renewed their conflicts with China at the E. and with Persia at the S. W., and in 569 formed an alliance with Justin II., then emperor of Constantinople, for the overthrow of the Sassanides. But this Turkish empire (which the Chinese called Tu-kiu, like all the attempts of the Turks at imperial domination, was an agglomeration of dissimilar peoples in one huge nation, with no common bond of union or citizenship, and its very weakness contributed to its weakness. In 744 the empire was overthrown by the attacks of the Hwei-he or Hwei-hu, as the Chinese named them (the Uigurs of western writers), another Turkish tribe who had previously been subjects of the Tu-kiu empire. There were at this time, and had been for some centuries, 8 distinct Turkish tribes or nations in central Asia. The Uigurs never attained to the vast power of their predecessors, but they were the first of the Turkish tribes to adopt a written language. At first they were Buddhists; but about the 4th century they became very generally the disciples of Zoroaster, and in the 9th or 10th century embraced Islamism, which had many doctrines suited to their taste. In the West their empire was overthrown in 848 by the Kirghes Tartars; but they maintained an independent kingdom in the valleys of the Thian-shan range till about A. D. 1000, when the increasing power of the Khitans in China compelled their emigration westward. The invasion of Genghis Khan overthrew the last remains of the Turkish empire in central Asia; but the prominent officers of that conqueror and his successors were taken from this very tribe of Uigurs on account of their superior intelligence. But while thus for the time waning in power in their ancient seats, the Turks were acquiring new territories in the West. In the 6th and 7th centuries they were already in possession of an extensive region in what is now Asiatic Turkey, and were pressing forward toward S. E. Europe. In the 9th and 10th centuries the Tooloomides and Ikshides, who were the reigning dynasties of Egypt, were Turks. In the 9th century a Turkish dynasty, the Taherides, ruled in Persia;

and their successors, the Gaznevides and the Ghurides, extended their sway from Persia to India between the 10th and 12th centuries. A more famous Turkish dynasty however than either of these was that of the Seljooks (see SELJOOKS), whose dominion extended in the latter part of the 11th century from the frontiers of China to the vicinity of Constantinople. Like its predecessors, this vast empire crumbled to pieces from its want of homogeneity, and the Seljookian sultans submitted to be the tributaries of the Mongol emperors. At the beginning of the 14th century the Ottoman empire was founded by Othman, a Seljook chief, and in the succeeding centuries spread over a vast territory in Asia and Europe. (See TURKEY.) The Turkish tribes which had submitted to the Mongol invasion in 1257, and still remained in the region of the Thian-shan, the Aral, and the Caspian, sent out colonies N. of the Caspian into that portion of southern Russia lying on the borders of the Black sea, where, under the name of Tartars, several tribes of them still occupy extensive territories. While acknowledging the Russian sway, they are still zealous Mohammedans. The Tartar invaders of Toorkistan, instead of impressing their own habits and language upon the Turks of that country, gradually became identified with the people they had conquered; and eventually, the Turkish element again predominating, in the age following the death of Tamerlane they had invaded and subdued Armenia and the countries bordering on the Tigris and Euphrates. From this region they were expelled in the 16th century by the Soofees. In the same century the Usbecks, a Turkish tribe, primarily inhabiting the southern provinces of Chinese Toorkistan below the Thian-shan mountains, and said to be descendants of the Ugurs and the Naimans, made their way westward and overran not only Independent Toorkistan, but the countries adjacent as far as the Euphrates, and were, after maintaining their power for more than a century, reduced to subjection by still another Turkish tribe, the Toorkomans. The Toorkomans and Usbecks are now, in the ancient seat of the Turks, the principal remaining tribes of that powerful race. The Kalmucks between the lower Volga and Don, the Bashkirs between the Volga and Irtish, and the Yakoots on the banks of the Lena, are also Turkish tribes, in which there has been some admixture of the Mongol element, but who yet preserve sufficiently the Turkish characteristics to be fairly admitted as belonging to the great Turkish family. The Yakoots are the only Turkish race which professes Shamanism.

TURK'S ISLANDS, or **TURQUES**, a group of islets which lie in the S. E. extremity of the Bahama archipelago, about 60 m. N. from the coast of the island of Hayti; pop. estimated at 1,200. Grand Key or Turk's is the principal island, and salt is the only article exported from the group. The number of the population fluctuates greatly at different times, as many people

are in the habit of coming over annually from the Bermudas to work at salt raking, returning when the season is over. This and the Caicos group constitute a U. S. consulate, of which the ports of entry are Grand Turk, Salt Cay, East Harbor, and West Caicos. The value of imports from the United States in 1860 was \$87,329.70, and of salt exported to the United States \$107,978.74. American vessels entered, 164, tonnage 86,534, which was a decrease of 68 vessels from the previous year, while the British shipping in the American trade had increased. The total exports from the district in 1858 amounted to about \$200,000, and the imports to \$175,000.

TURMERIC, the rhizoma of the East Indian plant *curcuma longa*, and also of the *C. rotunda*, of the natural order *singiberaceae*. The root is perennial, tuberous, and internally of a deep yellow or orange color. The plant is cultivated in various parts of Asia, particularly in China, Bengal, and Java. The root obtained from China is said to be the best. It is received in short cylindrical pieces about as thick as the finger, of a yellowish brown or greenish yellow externally, hard and compact, and easily pulverized to a yellow powder. It has a peculiar odor, and a warm, bitterish, and feebly aromatic taste. It yields to alcohol and ether a yellow coloring matter termed curcumine, the color of which is rapidly changed by alkalies to reddish brown; a property which is made use of in chemical analyses as a test for the presence of alkalies. For this purpose white unsized paper is dyed with a tincture or decoction of turmeric, and is kept in the laboratory carefully preserved from access of acid or alkaline vapors. This is what is called turmeric paper. The root had formerly some reputation as a medicine, especially for jaundice and other visceral diseases. It resembles ginger in its properties as a stimulant aromatic; and in India it is used chiefly as a condiment, especially in curries. In dyeing it affords a fine yellow color, but not permanent. In pharmacy it is employed to give a color to ointments and other preparations.

TURNBULL, ROBERT, D.D., an American clergyman and author, born at Whiteburn, Linlithgowshire, Scotland, Sept. 10, 1809. After being graduated at Glasgow university, he attended the lectures of Oshalmers and Wilson at Edinburgh, studied theology under Drs. Dick and Mitchell, united with the Baptist denomination, preached for a short time in Scotland and England, and came to the United States in 1833, settling in Danbury, Conn. In 1835 he accepted an appointment as a home missionary to Michigan, where he became pastor of the Baptist church in Detroit. Two years later he removed to Hartford, Conn., and became pastor of the South Baptist church in that city. In 1839 he was called to the pastorate of the Boylston street (now Harvard street) Baptist church in Boston, where he remained 6 years, since which time he has been pastor of the

first Baptist church in Hartford. In 1851 he received the degree of D.D. from Madison university. He has published "The Theatre" (Boston, 1840); "Olympia Morata" (Boston, 1842); "Vinet's Vital Christianity," translated, with an introduction and notes (Boston, 1846); "The Genius of Scotland" (New York, 1847); "The Genius of Italy" (New York, 1849); "Theophany, or the Manifestation of God in Christ" (Hartford, 1851); "Vinet's Miscellanies" (New York, 1852); "Pulpit Orators of France and Switzerland" (New York, 1853); "Christ in History, or the Central Power" (Boston, 1856); and "Life Pictures, or Sketches from a Pastor's Note Book" (New York, 1857). He has edited Sir William Hamilton's "Discussions on Philosophy," with a historical introduction; and was for several years the senior editor of the "Christian Review," a Baptist quarterly periodical.

TURNBULL, ROBERT JAMES, an American political writer, born in New Smyrna, Florida, in Jan. 1775, died in South Carolina in 1833. His father was an English physician, and his mother a Greek lady of Smyrna in Asia Minor. The father, Dr. Turnbull, in connection with Lord Hillsborough, obtained grants from the English government about the year 1772 for settling a Greek colony in Florida, which had been ceded to Great Britain by Spain in 1768. About 1,500 persons from the Mediterranean islands, chiefly Greeks and Minorcans, were induced to emigrate, and by them New Smyrna was founded. The project, however, was on the whole a failure; and Dr. Turnbull, adhering to the popular side in the revolution, forfeited his grants from government, and removed to Charleston, S. C. His son Robert James was educated in England, and after his return to America studied law in Charleston and Philadelphia, was admitted to the bar, and practised in Charleston until 1810, when he retired to the country, where he had a large plantation. His first essay as a political writer was a treatise on the penitentiary system, which attracted attention both in America and England. In 1827 he wrote many articles for the "Charleston Mercury," which were subsequently collected and published under the name of "The Orisis," and became the text book of the nullification party. In 1830 Mr. Turnbull published a treatise on "The Tribunal of Dernier Resort," in which he argued that "each state has the unquestionable right to judge of the infractions of the constitution, and to interpose its sovereign powers to arrest their progress and to protect its citizens." In 1831 he took a leading part in the "Free Trade Convention" which assembled at Columbia, S. C., and was the author of the report put forth by that body. He was conspicuous also in a similar convention which met at Charleston in Feb. 1832. On July 4, 1832, he delivered an oration before an assemblage of the nullification party, which is said to have had a marked effect upon the next election. In Nov. 1832,

he was a delegate to the convention of the people of South Carolina which passed the nullifying ordinance, and he wrote the address of the convention to the people. After the proclamation of President Jackson was received in South Carolina, and volunteers were raised in addition to the militia already organized to resist the federal government, he was the first to enlist as a private soldier. A lofty monument in Charleston, erected by the nullification party, commemorates his services to their cause.

TURNER, EDWARD, a Scottish chemist, born in 1798, died in London, Feb. 13, 1839. He was educated at the university of Edinburgh, and in 1828 was appointed professor of chemistry in University college, then called the university of London, a position which he filled until his death. He is chiefly known by his "Elements of Chemistry," which has passed through numerous editions. His labors were devoted principally to inorganic chemistry.

TURNER, JOSEPH MALLOD WILLIAM, an English painter, born in London, April 23, 1775, died in Chelsea, Dec. 19, 1851. His father pursued the calling of a barber and hairdresser in Maiden lane, Covent Garden, and in this neighborhood the painter passed his childhood—a circumstance noticed with some particularity by Ruskin on account of its presumed influence upon his style and thoughts in after years. Having at 5 years of age accompanied his father on a professional visit to the house of a Mr. Tomkinson, he immediately afterward drew from memory a copy of a lion on an emblazoned coat of arms which he had seen there with such accuracy as to astonish his parents, who thereupon, it is said, conceived the idea of making a painter of him. Thenceforth his pencil was seldom idle, and, with water colors and brushes supplied by his father, he made sketches of the principal objects which his limited field of observation presented. After a year or two of schooling, during which he occupied himself more with sketching trees, cattle, and landscapes from nature, than with books, he was employed by the engraver John Raphael Smith to color prints, to which occupation succeeded the painting of skies, backgrounds, and other accessories for architectural designs. The example of Cozens and the friendship of Girtin, two of the founders of the British school of water colors, led him to attempt higher things; and in 1790, having the year previous become a student at the royal academy, he exhibited a water color "View of the Archbishop's Palace, Lambeth." Other works depicting scenes in the neighborhood of London followed, and with each year he showed increasing power and originality, infusing more light into his pictures than other contemporary artists, and occasionally essaying some novel effect derived from a close study of nature. In 1793 he was engaged to illustrate Walker's "Itinerant" and the "Pocket Magazine;" and during the next 5 or 6 years he made sketches for this purpose in many

parts of England, filling up his intervals of leisure by giving lessons in drawing. Although until near the commencement of the present century he painted chiefly in water colors, a branch of the art then by no means in high estimation and but imperfectly developed, the brilliancy and singular fidelity of his finished drawings began to attract attention, and by many critics of the day his preëminence in landscape painting was even then predicted. The royal academy ratified this opinion by electing him in 1799 an associate, and in 1802 an academician. He had hitherto confined himself chiefly to representations of English or Welsh scenery, but with the acquisition of academic rank he put forth his strength in such ambitious subjects as "The Fifth Plague of Egypt," "The Army of the Medes destroyed in the Desert by a Whirlwind," and "The Tenth Plague of Egypt," executed in oils; but these, in spite of their imaginative power, were less popular than his "Dutch Boats in a Gale," "Fishermen upon a Lee Shore in Squally Weather," or "Falls of the Clyde." The surpassing excellence of his representations of marine scenery and of water under all conditions was first recognized in the latter class of pictures. In 1802 he first visited France, commemorating his arrival in that country by a picture of "Calais Pier;" and thenceforth at regular periods he made extended and solitary tours through France, Switzerland, and the Rhine land, the fruits of which were presented in manifold sketches, drawings, and finished pictures. In 1807 he was elected professor of perspective to the royal academy, and in this capacity delivered a few lectures, which according to the general account were little creditable to his abilities as an artist. He seems to have been unable to express himself with sufficient clearness to interest his classes, and cared little about imparting instruction, unless he perceived an ability on the part of his pupil to profit by his obscure hints. "Turner, though he was professor of perspective to the royal academy," says Ruskin, his biographer, "did not know what he professed, and never, as far as I remember, drew a single building in true perspective in his life; he drew them only with as much perspective as suited him." With his election as an academican terminates what is known as the first style of Turner, or that in which he studied and imitated the methods of Wilson, Gainsborough, and others of his predecessors, and elaborated the details of nature with a sobriety of color approximating to coldness. His second style, which in general terms may be said to embrace the period between 1802 and 1832 (although such a division is purely arbitrary, and is to be adopted for the sake of convenience only), commenced with an imitation of Claude Lorraine; and the desire to rival and if possible to surpass his model led to the publication in 1808 of his *Liber Studiorum*, the superiority of which over the *Liber Veritatis* of Claude does

not however afford a fair test of the comparative merits of the two painters; Turner's studies being elaborate and careful illustrations of all the principal forms of landscape composition, while Claude's are but incidental memoranda of pictures. In further competition with Claude he painted his "Sun rising through a Mist," "Crossing the Brook," "Apuleia in search of Apuleius," "Dido building Carthage," and some others of less note; but his individuality soon broke through the shackles of mere imitation, and subsequent to 1815 he worked according to his own ideas, indifferent to the examples of preceding masters. The variety of subjects he attempted during the 12 years previous to this time affords a curious illustration of the originality and audacity of his genius. Not content with the production of works like the "Shipwreck," the "Wreck of the Minotaur," and the "Snow Storm—Hannibal crossing the Alps," which presented with incomparable power the elements in their wildest fury, or like the "Edinburgh from Calton Hill" and the "Falls of Schaffhausen," he ransacked Lempriere's dictionary for subjects, painted humorous and whimsical pieces, such as a "Country Blacksmith disputing upon the Price charged to the Butcher for Shoeing his Pony," and even attempted sacred history, having in 1808 exhibited a "Holy Family." From 1815 his conceptions expanded with his increasing observation and knowledge of the phenomena of nature, and subsequent to his first visit to Italy in 1819 his style may be said to have matured into its full splendor. Between 1820 and 1840, when he returned from his third and last visit to Italy, the second having been made in 1829, he was perhaps greatest and most original; and his "Bay of Baia," "Ulysses deriding Polyphemus," "Caligula's Palace and Bridge," "Childe Harold, or Modern Italy," "Slavers throwing overboard the Dead and Dying—Typhoon coming on," "The Fighting Temeraire towed to her last Mooring," and other works produced within this period, represent the highest efforts of landscape painting in composition, in color, and in the general vein of poetic sentiment which pervades them. The tendency toward brilliancy of light and color which several of these works evinced became during the last 10 years of his life the most marked feature of his style; and, disregarding individuality of form or local color, he made light with all its prismatic varieties the sole object of his studies. The consequences were lamentable to his reputation, and his remaining works, loosely executed, untrue to nature, and apparently without meaning or form, excited the ridicule or pity of most who beheld them. It was said that the hanging committees were sometimes in doubt which side of his pictures to suspend uppermost, and that the artist had by mistake forwarded his palette set with colors instead of a picture. There are however some who profess to see amid the extravagances of his latest style a solid foundation of truth

and infinite suggestiveness; but the number of such persons is inconsiderable, and according to the popular opinion his later pictures might better never have been painted. In one department of his art, however, that of designing from nature for illustrated works, Turner remained in the highest request until the close of his life; and in none of his productions does he appear more truly great than in his finished drawings and engraved designs. Among the most famous of these may be mentioned his "Rivers of England," "Rivers of France," "England and Wales," "Scenery of the Southern Coast," and the exquisite illustrations of the poems of Rogers, Byron, Scott, and others, in all of which he shows a knowledge of landscape in its infinite variety of forms superior to that of any other artist on record. Fine line engravings of large size have also been executed from some of his most remarkable paintings; and, as if conscious that his reputation was destined to rest in a great measure upon this class of his works (an anticipation which has partially proved correct, as many of his pictures, owing to a careless use of pigments and varnishes, are rapidly losing their effects and crumbling to decay), he devoted much time to retouching the proofs, adding and altering the details down to the minutest twig. From 1790 until his death he contributed to every academy exhibition except three, sending altogether 259 pictures.—Turner was never married, and throughout life exhibited an eccentricity of character, which, whether real or assumed, subjected him to many injurious aspersions. Though reputed unsocial, reserved, and uncharitable in his opinions, he was, according to Lealie, in reality of a social nature, and, if not given to praising the works of his contemporaries, was never known to disparage them. One of his most prominent characteristics was a love of mystification, under the influence of which he worked and travelled alone, often concealed his abode for months from his most intimate friends, and died finally after a protracted absence from London in lodgings at Chelsea, where he was known under the name of Booth, and commonly supposed to be an admiral in reduced circumstances. Of his parsimony many exaggerated stories have been related; but the provisions of his will bequeathing the bulk of his large fortune to found an asylum for decayed artists, to be called "Turner's Gift," and such of his pictures as were in his possession to the nation, show that he hoarded his money for no purely selfish purpose. His intentions were partially thwarted by the unskilful manner in which the instrument was drawn; and while his pictures, drawings, and sketches have fortunately been secured to the nation, the remainder of his property, with the exception of £20,000 appropriated to the royal academy, was divided among his next of kin. The oil paintings, numbering upward of 100, and comprising specimens of his style from the outset to the ter-

mination of his career, are now deposited in the national gallery. Two of them, the "Bulking of Carthage," which he esteemed so highly that he is said to have announced his intention of being buried in it, and "Sun rising through a Mist," with a feeling prompted by his early rivalry of Claude, he directed should be hung next to prominent works by that master. The drawings, studies, and sketches, numbering altogether upward of nineteen thousand, constitute with the paintings a legacy of inestimable value, and have been cleaned, mounted, and arranged by Mr. Ruskin. "Turner," says Lealie in his "Autobiographical Recollections," "was short and stout, and he had a sturdy, sailor-like walk. There was in fact nothing elegant in his appearance, full of elegance as he was in art; he might be taken for the captain of a river steamboat at the first glance; but a second would find far more in his face than belongs to an ordinary mind. There was that peculiar keenness of expression in his eye that is only seen in men of constant habits of observation. His voice was deep and musical, but he was the most confused and tedious speaker I ever heard." Though not addicted to literary pursuits, he appears to have tried his hand at a poem in blank verse entitled "The Fallacies of Hope," extracts from which, for the most part "destitute of rhyme, rhythm, or reason," were frequently appended to the titles of his pictures in the royal academy catalogues.—The prominent position which Turner now occupies is due in no slight degree to the eloquent if not always discriminating criticisms of John Ruskin, whose "Modern Painters," conceived in an intense enthusiasm for the genius of the painter, contains an exhaustive analysis of his works. Time alone can determine whether he was altogether fortunate in his panegyrist; but without accepting the dogma of Ruskin that "none before Turner had lifted the veil from the face of nature," we may unhesitatingly pronounce him a consummate master of composition, unrivalled in his knowledge of landscape and in his capacity to express the variety as well as the grandeur of nature. Dr. Waagen, a critic not given to hero worship, declares that no landscape painter has yet appeared with so great a versatility of talent, and that but for his deficiency in a sound technical basis he would be the greatest artist in his peculiar department of all times. The only biography of Turner which has yet appeared is one by Walter Thornbury (2 vols., London, 1863).

TURNER, SAMUEL HURLBERT, D.D., an American clergyman, born in Philadelphia Jan. 23, 1790, died in New York, Dec. 31, 1861. He was graduated at the university of Pennsylvania in 1807, studied theology under Bishop White, was ordained deacon, Jan. 27, 1811, and in the following year became rector of the church at Chestertown, Md., where he remained until obliged to leave Maryland on account of his health in 1817. In Oct. 1818, he was elected

professor of historic theology in the general theological seminary in New York, and in 1821 professor of biblical learning and the interpretation of Scripture in the same institution. He was also in 1831 appointed professor of Hebrew in Columbia college. He published "Thoughts on Scriptural Prophecy," "Companion to the Book of Genesis," "Biographies of Jewish Rabbis," commentaries on the Epistles to the Romans, Hebrews, Ephesians, and Galatians, and other works.

TURNER, SHARON, an English historian, born in London, Sept. 24, 1768, died there, Feb. 13, 1847. He was by profession an attorney, but retired from business in 1829. Having devoted much time to the investigation of Anglo-Saxon remains, then an unexplored mine of historical wealth, he published a "History of the Anglo-Saxons" (4 vols. 8vo., 1799-1805; new ed., 3 vols. 8vo., 1836-'9), and subsequently brought out a "History of England in the Middle Ages, with a Continuation to the Death of Elizabeth" (5 vols. 4to., 1814-'29; 3d ed., 9 vols. 8vo., 1839). His other works are: "A Sacred History of the World, as displayed in the Creation and subsequent Events to the Deluge" (3 vols. 8vo., 1836-'9); "Sacred Meditations by a Layman;" "A Prolusion on the Greatness of Britain, and other Subjects;" and "Richard III., a Poem."—SYDNEY, an English clergyman, son of the preceding, became in 1838, soon after taking orders, superintendent of the reformatory school of the philanthropic society in London, and effected its reorganization as the Red Hill reformatory near Reigate in 1846; and since 1857 he has been inspector of reformatories in England and Scotland. He has published "Reformatory Schools, a Letter to C. B. Adderley, Esq., M.P." (8vo., 1855); a new and enlarged edition of his father's "Sacred History of the World" (1858); several pamphlets on reformatory education; and 8 voluminous reports as inspector of reformatories.

TURNER, WILLIAM, an English physician, naturalist, and divine, born in Morpeth, Northumberland, about 1520, died July 7, 1568. He studied medicine and divinity at Cambridge, and took a decided part in the religious discussions of the time, whence he became obnoxious to the dominant party, and was imprisoned. After his release he went to the continent, and studied natural history at Zürich and Bologna. Upon the death of Henry VIII. he returned home, and in the reign of Edward VI. became physician to the protector Somerset, and later prebendary of York, dean of Wells, and canon of Windsor. When Mary ascended the throne he was again obliged to fly the country, but returned upon the accession of Elizabeth, and was reinstated in all his original benefices. The work on which his reputation rests is his "Herball," the first book of which appeared in London (fol., 1551), and the second at Cologne (1552). He wrote also *Atium Præcipuarum, quarum apud Plinium et Aristotelem Mentio est, Historia* (8vo., Cologne, 1554); the account of

British fishes in Gesner's *Historia Animalium*; and several works on controversial divinity.

TURNER, WILLIAM WADDEN, an American philologist, born in London in 1810, died in Washington, D. C., Nov. 29, 1859. He was brought to New York at the age of 5 years, received an ordinary school education, and was apprenticed to his father's trade, that of a carpenter; but after 8 years his fondness for reading and other causes led him to become a printer, and he accordingly apprenticed himself to that trade in 1829. He possessed a remarkable facility in the acquisition of languages, and at the age of 26 was master of French, Latin, German, and Hebrew; he then studied Arabic with Prof. Nordheimer, and the two proposed to publish together an Arabic grammar, but, finding little encouragement, prepared instead of it a Hebrew grammar and chrestomathy. Mr. Turner went to New Haven to print it, as the only sufficient supply of oriental type was to be found there and at Andover, and worked upon it as a compositor during the day, while he prepared the manuscript at night. After the completion of this work Mr. Turner added to his linguistic attainments a knowledge of Sanscrit and most of the other leading Asiatic languages, and subsequently turned his attention to the languages of the North American Indians, and edited a grammar and dictionary of the Dacotah language, which was published by the Smithsonian institution. In 1842 he was appointed instructor in Hebrew and its cognate languages in Union theological seminary, New York, and remained in that position till 1852, when he received the appointment of librarian to the patent office at Washington, where he continued till his death. Beside the works already mentioned, Prof. Turner translated Von Raumer's "America and the American People," and part of Freund's Latin dictionary (1851), and assisted Dr. Kaufmann in translating MacKeldey's "Compendium of Modern Civil Law."

TURNERS. See GYMNASIUMS.

TURNING, the art of shaping wood, metal, or other hard substances into forms having usually curved, and most commonly circular outlines, and also of executing figures composed of curved lines upon plane or cylindrical surfaces, by means of appropriate tools and a machine called a lathe. Theodore of Samos, named by Pliny as the inventor of turning, may have originated the application of the process to the shaping of hard substances. The principle of turning is simple. A piece of wood or other hard substance being so fixed in a horizontal position by pivots or otherwise at its two ends as to be allowed to revolve freely about an axis in the direction of its length, and caused to turn rapidly in this manner, while a chisel or other cutting tool is approached to the piece so as to meet it as it advances on one side, and held firmly to it, the tool will cut away from the piece at that place all the material outside of a circle whose radius is the distance of its point from the axis of motion; thus it will give to

the part a circular outline, and will reduce the diameter of this circle as its point is advanced further into the material. The tool being gradually moved along the length of the turning piece, it can thus be made to reduce successively the entire length to the circular outline, and, by cutting to different depths in different parts, to produce a turned piece marked with circular grooves, or other forms of curved surface, as required for ornament or use, and as seen in turned bed posts, the turned legs of chairs and tables, &c. The piece to be cut or worked to a required form is known as the "work." In the simpler modes of turning, the cutting tool is held to this by the hand, but steadied by means of a fixed rest. Outside circular turning is the most common, and is known as "centre work." With lathes of peculiar construction the work may be turned hollow, or bored or reamed, or turned both inside and out.—The primitive and most simple kind of horizontal lathe is that known as the pole lathe. In this, from a bed formed of two horizontal planks or beams with a narrow space running along between them, and supported at a suitable height, two uprights or puppets rise, one stationary at one end of the bed, the other having a tenon passing through the space and secured by a wedge beneath, so as to be movable along the bed, to accommodate it to the length of the work. Near the upper end of each puppet, on the sides facing each other, is a conical iron or steel point, the two being in the same line. The piece, being cut to the proper length, is placed between the points, and the movable puppet brought up so that both points are pressed slightly into its ends; the line between these is the axis about which the piece will revolve. The fixed rest is placed conveniently for steadying the tool; while to turn the work, a groove being cut about it, usually at the left end, a stout cord or catgut is passed twice or oftener about the piece, then drawn straight and attached below to a treadle to which the workman's foot is applied, and above to an elastic pole or lath fixed at one end to the ceiling overhead, whence, probably, the name pole lath, or simply lath, or lathe. The workman holds the gouge or chisel to the work, and pressing down the treadle with his foot, the work is caused to spin rapidly round toward the point of the tool; and so long the latter takes effect. When the treadle, having come quite down, is released by the foot, the recoil of the lath carries back the cord and work in the reverse direction, and the tool does not cut. If it is required to turn the entire length of the piece, the cord must be shifted after a time to the finished part. This contrivance serves for ordinary wood turning; but on account of its imperfections, and especially the loss of time during the return or rising of the treadle, it is now little used. For light or fine work, the pole is often replaced by an elastic bow and string over head, the cord giving the revolution being attached to the middle of the

string. But the forms now more usual, and especially for heavy work, are: 1, the foot lathe, in which the treadle is by a link made to give motion to a crank, from a larger grooved wheel upon which a cord crosses in form of an 8 to a smaller grooved wheel or pulley fixed upon an axis at one end of the work, and giving motion to it; 2, the hand-wheel lathe, in which the power is applied by the action of one or two persons in turning a wheel, from which a band communicates movement to the axis and work; and 3, the power lathe for the heaviest work, moved by horses, water, or steam. Any wooden lathe, such as is used by turners in wood, is also distinguished as a bed lathe; while those of iron, for the best work in metals, are called bar lathes. In any form of lathe such as those now considered, the turning axis at one end of the work, to receive the power and give motion to the piece, in place of the simple point which can be used in the pole lathe, becomes indispensable. This axis is called the mandrel, and sometimes the "live spindle." To support this properly, the fast head, or headstock—that which is fixed and (in reference to the workman's position) at the left hand end of the lathe—is constructed with two upright pieces at a suitable distance apart, and firmly secured to the bed. Through the inner or front one of these uprights is a circular opening containing a metallic ring or collar, within which the mandrel turns, and just within or in front of which it terminates in an exterior or interior screw or other device for holding the chucks, presently to be noticed, that fix the corresponding end of the work. Into a depression in the opposite end of the mandrel, the steel point of a screw which is worked by hand through the outer upright is advanced so as to fit closely; and the two uprights thus, by means of this point (or sometimes a collar), and of the collar already mentioned, support the mandrel, and keep it in the position required. On the mandrel the speed pulleys and the larger wheel for slow motion are placed; and directly beneath these, under the bed, in foot lathes, are the corresponding wheels upon the axis of the crank, this axis being situated at the required height, and its ends turning in collars in the standards at the ends of the machine. When the end of the mandrel extending through the inner upright terminates in, or is furnished at its middle part with, a point for entering one end of the work, this is called a "centre;" this point or centre must be accurately in the line of the axis of the mandrel; and this axis must also be perfectly parallel with both the direction of the bed and that of the centre line of the slit or space along which the movable puppet is shifted. By means of a suitable shoulder upon the mandrel, or by giving to the part of it within the collar and to the collar itself a conical form, it is prevented from sliding endwise within the headstock. The movable upright, or tailstock, has a tenon or foot pass-

ing down through the space in the bed, upon which it is made to fit accurately; and it is held firmly by screwing up against the under side of the bed the nut of a hand screw in which the foot terminates; by loosening this, the tailstock can be shifted to any position required by the length of the work, and again fixed. The point or "centre" of the tailstock must be in the same line with the axis of the mandrel; and in the better styles of lathe, this point can also be advanced through the upright by turning a horizontal screw of which it forms the inner end, for the purpose of tightening the work. In power lathes, the tailstock may be advanced along the bed by means of a hand wheel and a pinion working in a horizontal rack. The fixed and movable uprights may be of cast iron; but when the bed of the lathe is of iron, the puppets are sometimes made of oak or mahogany, as lathes entirely of metal are subject to an inconvenient elastic tremor. The construction now described is essentially that of the best foot lathes for centre work, and which are adapted to turning all ordinary materials, whether metals, ivory, or wood. The chucks, or contrivances fixed upon the end of the mandrel, are of various forms and construction, according to the kind of work they are intended to secure; the most common being the screw chuck, the hollow, drill, universal, concentric or die, and ring chuck, and the carrier and driver. The crowning improvement, moreover, in the adaptation of the lathe to accuracy of work, and to that of all varieties, is attained through the invention of the slide rest, a carriage upon which the tool is supported, and by the construction of which it can be moved along the work by the machine or by hand, and at the same time advanced toward it, or set at any angle, as the character of the work may require.—In wood turning, the woods most used for common toys are willow, whitewood, beech, birch, and alder; for the best wooden wares, sycamore, apple, pear, plum, &c.; for work of great strength or of close texture, and for certain peculiar purposes, box, walnut, mahogany, oak, or elm, pine, &c. The wood to be turned may be prepared by rounding with a hatchet and rasping; and for many purposes the centres of the ends must be accurately found, as by laying the piece on a true plane, striking arcs on its ends with the compasses, turning on the several sides successively, and finding the point indicated by the intersections of the arcs. Soft woods are most difficult to turn; the velocity should be great, and the tool presented nearly to the top of the work, and held very firmly, cutting only a thin shaving. For hard wood and other turning, the tool is presented a little above the centre line of the work. Generally, wood requires the highest velocity; brass and bell metal a velocity not more than one half as great; wrought iron and copper still less, the tool being kept cool by water trickling upon it; steel still more slowly; and cast iron slowest of all. Common gouges, with

cutting edge of hollowed and semi-circular form, are used for roughing out wood work, and chisels for smoothing it and bringing it to form; while for ornamenting, or executing various arrangements of broken and curved surface and outline, the chisels (then sometimes called gravers) receive an almost endless variety of general shape and of cutting edge. After being turned, the work is often polished by pressing against it suitable substances while it revolves. Soft wood is usually polished with shark's skin or Dutch rushes; ivory and horn, with pumice stone and chalk; metals, with tripoli or putty powder.—In the cases thus far considered, there is but one axis or centre line of the work; that is, the centre line is a fixed direction throughout the process of cutting. But it is desirable to execute work in which the cutting in different parts or moments shall be in reference to two or more different axes through the solid or surface acted upon. A simple mode of effecting this, sometimes resorted to, is that of fixing the work successively with the different axes, and turning it at two or more operations. But practically, a far more complete and satisfactory result is attained, the forms executed being variable at the pleasure of the workman, by incorporating into the lathe devices which shift the place or direction of the single axis of motion, and in a defined manner and degree, while the work is rotated and the tool continually acting upon it. This species of turning, with a variable centre of the work at different moments, takes several names according to the devices employed or the particular results secured, as eccentric, geometric, oval, and rose-engine turning. Such work is said to be figure-turned; and the general principle is that of employing some form of chuck which shall give an oscillation or lateral movement to the axis of the work during its revolutions, so as to insure those deviations from a simple circular application of the cutter, required for the intended form or figure. The chucks employed are designated as the eccentric, the geometric, the oval, or more properly elliptical, and as rosettes; while a straight line chuck can also be employed to cut plane surfaces or square work. In all work of this character, the amateur turner prides himself not only on the delicacy and elegance of his results, but quite as much on the difficulty of execution; and the value of turned work is often estimated by the degree in which it departs from the circular figure. For eccentric turning, a single eccentric chuck is one fixed upon a strong plate that can slide laterally within straight guides screwed upon the face of the mandrel, and which, having upon it a toothed wheel and click, is called the click-plate; the slide, and the nose upon it for carrying the work, can be shifted into various positions out of centre, before applying the cutter. In the double eccentric chuck, a second plate or slide at the back of the first, and at right angles to it, can further

vary the position of the axis. By aid of such a chuck, any required part of a disk can be brought in line with the centre of the mandrel, and holes bored in any part of it, or the edges hollowed out in curves of like or different radii, or polygons with curvilinear sides accurately produced. Ornamental work with these chucks consists mostly in the execution of variously curved figures on surfaces, without cutting away or changing the general outline, as in ornamenting ivory or fine work in wood. The ivory turner often employs a small instrument called an eccentric cutter, in which the tool revolves rapidly, being moved by a bow, and with which, by means of a single eccentric chuck, and a separate adjustment of the cutter, involved figures like those ordinarily requiring the double eccentric chuck are produced. For geometric turning, a chuck of similar name is employed. In this, a wheel concentric with the mandrel, while the latter and the chuck revolve, gives, by means of a train of smaller wheels, an independent movement to the click-plate and axis of the work. By varying the relative sizes of the wheels, by introducing an added wheel to cause the work to turn at the same time in a direction the reverse of that of the mandrel, and by changing the position of the tool, or giving movement at the same time to it, an almost infinite variety of curiously involved curved figures may be engraved or marked upon a plane surface to which motion is thus imparted under the point of the tool. It is by this machine that some of the most perfect rosettes and other lathe work of bank notes, in the United States largely relied on as a means for the prevention of successful counterfeiting, are executed. The figures will vary with the construction of the machine; of which, save by actual inspection or model, no duplicate can be constructed. The geometric lathe of the American bank note company of New York, the single one of its kind, is a foot lathe of highly complicated and perfect workmanship, the construction of which is said to have occupied three years' time, at a cost of \$10,000. Elliptical turning is accomplished by means of the elliptical or oval chuck, in which the pressure of an eccentric ring, moving within and clasped by rubbers, is made to draw the slide out of centre alternately in the opposite directions, so that a stationary tool, held to a plate to which this movement is imparted during a revolution of the mandrel, will describe an ellipse instead of a circle; while the size, direction, and form of the ellipses can also be varied; and, as in the other forms of lathe here described, the micrometer screw may be introduced for determining the accuracy of proportions in the work. Rose-engine turning is, perhaps, the form most generally applicable and employed for producing involved curvilinear figures, as for the embellishment of bank notes, or for other patterns on plates and blocks for printing and embossing. Thus, it is in use for gold, silver, and gilt work; and also for pro-

ducing on the cylindrical surface of copper, steel, or wooden rollers, borders or ornamental figures for impression upon calico, leather, and paper. The principle of construction may be briefly indicated as follows: the standards that directly support the two ends of the mandrel are not, as in other lathes, firmly set into the bed, but held beneath the line of the mandrel by a pivot at each end projecting from pieces set in the bed; an axis extends across between these pivots, uniting the standards, and parallel with the mandrel. Thus the mandrel, while made to revolve, can also oscillate or swing laterally on the pivots, means being employed for this purpose to push it to one side, and a strong spring continually acting to restore or bring it back, as soon as allowed, from any position into which it may thus have been forced. Suppose, now, the work is a flat metallic plate affixed on the face of the chuck; that the figure is a waving or scalloped line, or a combination of such to be engraved or cut in the face of the plate; and that the tool is held at a certain point against the plate by the slide rest, ready to execute the figure. The mandrel is now made to revolve, carrying round with it the chuck and work; and so far, the line executed should be a circle only. But the mandrel is so delicately hung that, while turning, it will obey every impulsion acting to displace or push it aside laterally from the line in which it begins to revolve; and carrying the chuck and work with it, the tool will then cut a line deviating by precisely like amounts from the circle. It only remains, then, to give the required deviations or deflections to the mandrel and chuck, and their effect will be exactly reproduced in the figure executed. To accomplish this, as many different pattern guides are mounted on the mandrel itself, as the number of the differently waved lines that may be needed. These pattern guides, called rosettes, are circular plates of gun metal or brass, each about half an inch thick, and having on its two sides the rim indented, waved, or scalloped in different patterns, so that each wheel can be used to give two separate figures. These rosette patterns may vary in diameter, and the waves on each wheel may be from 12 to 144 in number; the number of patterns thus put upon a single mandrel may be 12, 20, or more, according to convenience. The particular pattern that shall in any case be transferred to the work is simply determined by the employment of a movable rubber carriage, fixed on commencing the work, which carries firmly set upon it a horizontal bar of steel, 3 or 4 inches long, called the rubber; this has on one end a small smooth roller, and the opposite end is small, rounded, hardened, and polished; it can be reversed at pleasure, and being placed at a level with the axis of the mandrel, either the roller or the point becomes, by its connection with the fixed carriage and bed, a fixed point working accurately against the curving periphery of either pattern upon any given rose-

wheel, and being continually resisted by the spring which pulls in the opposite direction, the combined effect is to deflect the mandrel and work precisely with the variations of outline of such wheel. The point of the rubber is substituted for the roller when the indentations of the pattern are very fine. To insure a more uniform movement, and to communicate the motion while allowing the oscillations of the mandrel, the engine is driven by a hand winch with a band passing round a foot wheel, while a second band passes from a small pulley on this axis to the mandrel pulley. By shifting the slide rest as required, a number of like concentric curves are executed; and by employing and cutting one pattern over another, an endless variety and complexity in the figures may be obtained.—Of the few machines which have been invented for turning irregular forms, in heavy or ordinary work, that of Blanchard is perhaps the best known and most successful. (See BLANCHARD, THOMAS.)—For further information respecting the tools and materials used in turning, and for many other details, see Holtzapffel's "Turning and Mechanical Manipulations" (8 vols., London, 1847-'62); and for the general subject, see article "Lathe" in "Appleton's Dictionary of Machines," &c. (New York, 1857), and Valincourt's *Nouveau manuel complet du tourneur* (3 vols., Paris, 1848-'53).

TURNIP, an esculent root known in gardening and agriculture. The common or field turnip originated by a long cultivation of the wild *brassica rapa* (Linn.), a biennial of the natural order of *crucifera*, and growing spontaneously in Great Britain and Europe. Its root is small, round, fleshy, tapering downward with a few fibres into a radicle; the leaves near the root are lyrate-pinnatifid, jagged, rough, and green, with fleshy petioles; the stem 1 to 4 feet high, branched, with nearly entire and smooth leaves; the flowers of a pale yellow, the pods (siliques) erect, slender, linear. The field or garden turnip is distinguished by its flattened root, expanding beneath the origin of its stem into a thick, round, fleshy tuber. It is subject to great variation in the size and weight of the root, owing to its tendency to enlarge in rich or proper soils; and it may differ in its flavor, or in the shape of the foliage, or even in the color of the root. A distinct permanent variety is the tankard or decanter turnip, in which the root is of an oblong form, and of which there are red and white kinds. The roots of this variety are, however, of a looser texture, and it is less hardy than the common turnip.—The Swedish turnip or ruta бага, also extensively grown as a field crop and for feeding cattle, originated from the *B. campestris* (Linn.), a plant indigenous to Europe. Its young leaves are hairy, but the older ones are smooth and glaucous, lyrate-toothed, those of the stem cordate-amplexicaul, acuminate; the flowers whitish yellow. The root of the ruta бага in its best condition is yellow both externally and internal-

ly; when the flesh becomes white and the apex of the root runs up into a sort of stalk or stem during the first year, it is considered inferior; and on blossoming, the flowers have been observed to be of a deeper yellow.—The French turnip originated from the *B. napus* (Linn.); its leaves are smooth and glaucous, the lower ones petioled, lyrate-pinnatifid, the upper oblong, cordiform-amplexicaul; the flowers yellow; the pods linear. The esculent variety is the *navet* of the French, the root forming an oval tuber below the crown or origin of the stem. There are at least 3 varieties of this sort distinguished by their color: the white, which is the most common; the yellow, of a more delicate flavor; and the black, so called from the blackish tint of its skin. The French turnip is considered sweeter and freer from any acrid properties than the field or garden turnip, and it is much prized by some for the table.—Botanically considered, the French, Swedish, and English or field turnip are related to the cabbage, and likewise seem to hold intimate relations to each other, so that their specific differences have been a matter of much uncertainty.—In Great Britain, where the turnip culture is of great importance as preparatory to a system of successive crops, and where it has become essential to agriculture, the different kinds are exceedingly numerous, and have been obtained by careful seed sowing, hybridizing, and experimental processes to procure the best varieties. Such a need does not exist in the United States, where productive crops of Indian corn will be found better suited for breaking up new ground and fitting it for future operations. Our drier atmosphere and our liability to droughts render turnips as a crop more uncertain, yet by careful management they can be raised with profit. Lands in tillage, of almost any nature, especially those of a light sandy loam, can be sown with turnips, the Swedish and the French turnips requiring the deepest and the best. After taking a crop of grass from the field, it may be broken up, manured, harrowed, and sown with ruta бага, thinning if the plants stand too thickly in the rows, hoeing to keep them clear, and pulling the roots in November. It has been found on experience that, generally speaking, the sorts originating in this country are better suited to our climate, and their seeds command higher prices, than the English or continental seeds. Of 52 sorts of turnip seeds imported from abroad by Mr. David Landreth of Philadelphia, he found two only which he thought worth perpetuating. The catalogues however advertise for sale about a dozen, some designated as American, of which perhaps the red strap-leaved and the white strap-leaved, the long French white, and Skirving's ruta бага are among the best. The turnip is subject to much injury from insects, and in Europe entire fields have been destroyed by a small coleopterous insect, which feeds on the seed leaves and growing foliage. (See TURNIP FLY.) Plant lice or aphides and

several larvae injure the roots, and they sometimes grow distorted into what is called clubbing. No proposed remedies have been so successful as a clean and careful cultivation, sowing abundance of seed, and encouraging birds which feed on insects. The field husbandry of turnips was familiar to the ancient Gauls, and as garden vegetables they were not unknown to the Greeks and Romans.

TURNIP FLY, a name given to several insects of different orders, but especially to the small chrysomelid beetles of the genus *altica* (Illig.), which attacks the turnip in its various parts and stages of growth. In the genus *altica* (Gr. *ἀλτικός*, skilled in leaping) the body is very convex above, oval, with short thorax and wide head; antennae slender; hind thighs very thick and formed for leaping; surface of the body generally smooth and shining, and often prettily colored; claws notched and hooked, enabling them to keep firm hold of the leaves of plants on which they feed, especially the cruciferous vegetables, to which they are often very injurious. They are all very small, the largest not more than 2 lines long and 1 wide; most are shining green, tinged with brown or yellowish. The turnip fly of England is the *H. nemorum* (Illig.); it devours the seed leaves of the turnip as they appear above the ground, continuing its ravages all summer; in winter it conceals itself in some dry and sheltered place, laying its eggs in spring on the leaves; the larvae eat the soft pulpy substance, making little galleries in which they undergo their changes, and in this way are as injurious as the full-grown beetles; they are slender grubs, tapering at each end, with 6 legs, and become perfect insects in a few weeks, a constant succession occurring through the summer. What they lack in size these beetles make up in numbers and voracity; the loss to the turnip crop from their ravages is sometimes considerable, in a single year in Devonshire amounting to half a million of dollars; they like sunny places, and are rarely found in shady fields or beds, cold, shade, and rains being the natural protection against their attacks. The best method of ridding the plants of these beetles is to water the leaves carefully and regularly with a solution of lime or other alkali; sprinkling lime or the dust of chalky roads upon them when wet with dew, the infusion of wormwood, the decoction of walnut leaves, and the smoke of burning straw and weeds will also free the leaves of this pest; the farmers accelerate the growth of the crop as much as possible, keeping them off till the turnip is in the rough leaf, when it is safe. The stages of this insect's growth are fully described in vol. ii. of the "Transactions of the Entomological Society of London," by Mr. Le Keux. The *H. striolata* (Fabr.), the wavy-striped flea beetle of the United States, much resembles the preceding; it is less than $\frac{1}{10}$ of an inch long, shining black, with a broad, wavy, buff stripe on each wing cover, and the knees and feet reddish

yellow; it is abundant on the seed leaves of the turnip and other plants early in May, in some seasons threatening to be almost as injurious as the European insect; the same remedies have been found effectual here.—Among the lepidoptera, the *pontia oleracea* (Harris), the potheb or white butterfly, is often called turnip fly. The wings are white or yellowish, dusky near the body; back black, and antennae blackish with narrow white rings; the expanse of wings about 2 inches. Toward the beginning of June it may be seen fluttering over turnip and cabbage beds for the purpose of attaching 3 or 4 of its eggs to the under side of the leaves; the eggs are yellowish, pear-shaped, ribbed longitudinally, and $\frac{1}{10}$ of an inch long; they are hatched in about 10 days, attain their full size of $1\frac{1}{2}$ inches in 3 weeks, when they are pale green, and eat irregular holes in any part of the leaf; they pass a chrysalis state of 11 days, suspended by silken threads attached to the hind feet and fore part of the body in some protected place; they are again abundant toward the beginning of August, laying eggs for a 2d brood, the chrysalids from which survive the winter, coming out perfect insects in May or June; the chrysalis is $\frac{1}{2}$ of an inch long; the larvae are eaten by titmice and other insectivorous birds; the chrysalids can be collected on boards placed for them near the ground, and the butterflies are easily caught in bag nets, as they fly low and lazily. This species is rarely found south of the latitude of New Hampshire.—Some dipterous insects, as the flower flies (*anthomyiidae*), in the larva state infest the roots of turnips, &c., eating also the pulpy parts of the leaves and stem; in this state they closely resemble the maggots of common flies.

TURNSOLE. See HELIOTROPE.

TURNSPIT. See TERREER.

TURNSTONE, a wading bird of the oystercatcher family (*hamatopodidae*) and genus *streptilas* (Illig.), so named from its turning over by the strong bill the stones and weeds along the margins of the sea and of lakes and rivers in search of insects, mollusks, and crustaceans which hide beneath them. The only well characterized species, *S. interpres* (Illig.), is about 9 inches long and 18 in alar extent; above it is irregularly variegated with black, dark rufous, and white; head and neck white above, with numerous spots and stripes of brownish black; in front of eyes and on throat white, usually bordered with black; lower parts, back, rump, and under wing coverts, white; quills brownish black, with white shafts; tail white at base and tip, with terminal half brownish black; conspicuous white bar on wings, bill black, and legs orange. The bill is shorter than the head, compressed, obtusely pointed, and slightly bent upward at tip; nasal groove very wide and shallow, for half the length of the bill; legs moderate and stout, with tarsi scaled in front; toes short and not webbed, the hind one touching the ground; wings long, the 1st quill longest; tail

moderate and rounded. It is generally seen in small flocks of 5 or 6, sometimes in company with various sandpipers; it is not at all shy, and emits a loud whistling note during flight; in its spring and summer dress it is a very handsome bird; the eggs are $4\frac{1}{4}$ by $1\frac{1}{4}$ inches, pale yellowish green with a few black lines and irregular patches of brownish red. It is one of the most widely distributed of birds, being found throughout North America on the Atlantic and Pacific shores, in Europe, at the straits of Magellan, Cape of Good Hope, the East Indies, Australia, and indeed in most parts of the world; in Great Britain it comes in August and remains till May, when it goes north to breed. The *S. melanocephalus* (Vig.) differs only in the prevalence of the dark color on the head, breast, and upper parts; it is abundant in western North America, and is probably only a variety of the common turnstone.

TURPENTINE, a liquid or semi-solid oleo-resin, which exudes naturally, or through incisions, from the wood of most coniferous trees, such as the pine, larch, and fir; also the thinner liquid obtained from this by distillation, which is more properly known as oil or spirits of turpentine. American turpentine is principally derived from the *pinus australis* (Mx.; *P. palustris*, Willd.), or the "long-leaved pine," which grows very abundantly near the coast in the south-eastern states, especially in the Carolinas and Georgia. The *P. taeda*, loblolly or old field pine, also furnishes turpentine, which is generally less fluid than that from the preceding species; and smaller quantities are derived from some other species. The greater part of the common European turpentine is obtained from *P. sylvestris* (Scotch fir) of N. Europe, and from the *P. maritima*, found in its southern part and along the sea coasts; much of that derived from the latter tree is sold as "Bordeaux turpentine," so named from the port whence it is chiefly shipped. "Venice turpentine" comes from the larch (*larix Europaea*); Canadian turpentine, or "Canada balsam," from the American silver fir or balm of Gilead tree (*abies balsamea*), which abounds in Canada, Nova Scotia, and the mountainous parts of the northern United States; Ohian turpentine from the *pistacia terebinthus*; Strasbourg turpentine from the silver fir (*abies picea*), though the same name is often given to the product of the *larix Europaea*; Carpathian and Hungarian turpentines from *P. cembra* and *P. pumilio*; dammar turpentine, or "dammar," from the *P. dammara* of the East Indies; and the Dombeya turpentine from the *Dombeya excelso* of Chili. There are a few other substances considered as turpentine, of which little is known; and the different turpentines of commerce are undoubtedly often derived in part from other species than those to which they are commonly ascribed. The name turpentine is derived from the Greek *τερεβινθος*, the tree furnishing the turpentine of Chios, the principal variety known

to the ancients, and which is mentioned by Pliny.—Turpentine slowly hardens when exposed to the air, partly from evaporation of the more liquid portion, and partly from the resinification of this by oxidation. It softens and liquefies by heating, readily takes fire and burns with a smoky flame, and is completely soluble in alcohol and ether. In its crude state it is applied to very few uses. By the distillation of common crude turpentine with or without water, a volatile product, known as oil or spirits of turpentine, is obtained, and resin or rosin, also called colophony, remains in the still. (See RESINA.) The oil is generally purified by redistillation with caustic alkali, which removes traces of acid and resin. Its formula when pure is $C_{10}H_{16}$. It is a colorless mobile liquid, highly inflammable, with a characteristic, pungent, bitterish taste, and strong odor; should be neutral to test paper; of specific gravity 0.86, with a boiling point about 320° F. (specific gravity of vapor, 4.76); is perfectly miscible with ether and absolute alcohol, less so with ordinary alcohol, and hardly at all with water; dissolves readily the resins, oils, sulphur, and phosphorus, and softens and partially dissolves caoutchouc. It rotates a ray of polarized light to the right or left, according to its origin, that from *P. australis* generally to the right and that from *P. maritima* to the left; but the amount of the rotation is on an average not more than $\frac{1}{4}$ of that produced by quartz. When English oil of turpentine is simply heated in a closed vessel to about 470° F., it is converted into a mixture of several substances of exactly the same composition, but differing very much in their properties, and which may be separated by fractional distillation. The most important of these are isoterabenthene, a colorless liquid having an odor of stale lemons, a specific gravity of 0.848, and a boiling point of 350° F.; and metaterebenthene, a viscous yellowish liquid, with a disagreeable odor, a tendency to rapid oxidation, and a specific gravity of 0.918, which constitutes the residue in the retort after the heat has reached 660° F., forming about one third of the entire quantity of oil distilled, and is volatile without decomposition at a somewhat higher temperature. Both of these rotate polarized light to the left. These modifications may be produced at a lower temperature than 470° F. if the oil be heated with water, or with several of the chlorides, fluoride of calcium, and many organic acids. By the action of sulphuric acid on oil of turpentine, two other modifications, identical in composition, have been obtained: terebene, which boils at the same temperature and has a vapor of the same density as the unmodified oil, but is rather less oxidizable, and has an odor like that of oil of thyme; and colophene, a somewhat viscid liquid, of specific gravity 0.940, and a boiling point of 590° to 600° F., colorless by direct light, but so fluorescent as in some directions to appear of a dark indigo blue, with vapor twice as

dense as that of terebene. By decomposing artificial camphor by means of quicklime, two other modifications of oil of turpentine, identical with it in composition, are produced: camphilene, boiling at 273° F., and terebille. Neither terebene, colophene, camphilene, nor terebille has any rotatory action upon polarized light. Oil of turpentine forms one liquid and three solid hydrates, and with hydrochloric acid it forms several liquid and solid compounds, the latter having the appearance and smell of camphor, and termed artificial camphors. It very easily oxidizes, and a definite hydrated oxide ($C_{10}H_{16}O, 2HO$) is obtained by placing it in a jar filled with oxygen over water and exposed to sunlight, which forms crystals on the sides of the jar, while strong nitric acid acts so violently upon it as frequently to inflame the mixture. A large number of other organic compounds are also formed by the action of dilute nitric acid, several of the other acids, chlorine, &c., of most of which little is known.—The principal applications of oil of turpentine are in the preparation of paints and varnishes (see *PAINTS*, and *VARNISH*), in the India rubber manufacture (see *CAOUTCHOUC*), as a burning fluid, alone or mixed with alcohol (see *BURNING FLUID*, and *CAMPHENE*), and as a medicinal agent, used both externally and internally. It is one of the most energetic of the volatile oils; the vapor is quickly destructive to plants, and to those insects which respire by the whole surface, as wasps, lice, fleas, and worms. It appears to act more powerfully on the lower animals than on man, as the skin of the horse is blistered by it much more rapidly than that of man, and 2 drachms are said by Schubart to have killed a dog in 3 minutes, while human beings have taken 3 ounces without serious injury. In moderate doses it acts as a stimulant to the stomach, intestinal canal, liver, and kidneys, and promotes the evacuations of these organs. In chronic affections of the liver, obstructions from gall stones, &c., in chronic rheumatism and sciatica, sometimes in typhus and yellow fever, in Asiatic cholera, scarlet fever, obstinate constipation, many diseases of the urino-genital organs, and many other diseases where a stimulant action is required, it is a medicine of great value, as well as for intestinal worms, which it appears to directly kill, instead of destroying them by removing their means of nourishment. As a liniment for rheumatic and paralytic affections, for burns, &c., it is very useful; and in vapor it has been used as an anæsthetic and a substitute for chloroform. It is much recommended in hæmorrhage from various organs, and in childbed fever.—Common American or white turpentine of good quality is yellowish white, somewhat translucent, of a consistency varying from semi-fluid and very adhesive, though still brittle, in the middle of summer, to hard and dry in winter, and often contains small pieces of bark or wood; and the inferior sorts are harder and darker colored. When fresh and good, it con-

tains on an average 17 per cent. of essential oil. Much was formerly obtained from New England, but for a long time most of the supply has been derived from North Carolina and S. E. Virginia, and later from South Carolina, Georgia, Alabama, and Florida. The product of turpentine in North Carolina was estimated a few years ago at 800,000 bbls., of which 300,000 were exported in the crude condition, and the remainder distilled in the state. For full particulars of value, mode of collecting, &c., see *CAROLINA, NORTH*. In Georgia and Florida the annual product was estimated at the same time at 80,000 bbls.; and in Alabama, where the manufacture was commenced only a few years ago, the production, according to a recent estimate, was upward of 1,600,000 galls. of spirits of turpentine, with a residue of over 180,000 bbls. of rosin. The exports of spirits of turpentine from the United States in 1860 amounted to 4,072,093 galls., valued at \$1,916,289, and of crude turpentine and rosin to 770,652 bbls., valued at \$1,818,238. They are sent to nearly all parts of the commercial world, but the largest quantities are taken, in the order named, by England, Holland, Belgium, Hamburg, Bremen, Chili, Ireland, Brazil, and Cuba. The import of crude turpentine into England in 1858 was 12,323 tons, or about 86,260 bbls., and in 1859, 12,833 tons, or 89,832 bbls.—Common European or Bordeaux turpentine is collected by simply making incisions in the trunk or removing portions of the bark and collecting the juice in small troughs or in holes dug at the foot of the tree; and it is purified by heating and straining through straw, by exposing it to the sun in a barrel with holes in the bottom, or by heating it with steam in bags, through which the melted turpentine escapes. Thus prepared, it is whitish and turbid, and separates upon standing into two parts, one liquid and transparent, the other of the consistence and appearance of honey; and the commercial article often consists wholly of this latter portion. The substance called by the French *galipot* or *barras* is that part of the turpentine which concretes upon the trunk of the tree, and is removed during the winter; and this, when purified by melting in water and straining, is called white, yellow, or Burgundy pitch. (See *PITCH*.) Venice turpentine, so named because formerly an important article of Venetian commerce, is obtained by boring a hole in the spring into the heart of the tree, about 2 feet from the ground, in which a wooden gutter is inserted. It is a viscid liquid, of the consistence of honey, with a yellowish or slightly greenish color, a more agreeable smell than common turpentine, and a very acid taste. Most of what is sold as Venice turpentine, however, is said to be prepared by dissolving rosin in oil of turpentine, is very brown, and appears to be made chiefly in the United States. Strasbourg turpentine is procured, according to Duhamel, by climbing to the top of the loftiest pines by means of spiked shoes, one hand of

the collector being employed to sustain him, while the other holds a cow's horn or tin instrument of the same shape, with which he reaks the tumors, and soon fills the horn, which he then empties into a tin plate bottle hung at his girdle. This is done both in spring and autumn. The product is then filtered through the leaves of the *pinus excelsa*, and laced in a funnel made of the bark of the same tree rolled up. It is very transparent, almost colorless, and in France is very frequently employed in medicine. Canada balsam (see *BALAMS*) is often sold for Strasbourg turpentine in the shops. It is used in medicine, by opticians or mounting microscopic objects, &c., and for some other purposes. Chian or Cyprus turpentine is chiefly obtained from the islands of Chios and Cyprus, where incisions are made in the summer in the bark of the *pistacia terebinthus*, from which the sap falls upon smooth stones placed at the foot of the tree, and is afterward strained. It is a greenish white, transparent, tenacious liquid, of about the consistence of honey, with an agreeable odor and but little taste. As the annual product is small, it bears a high price, and is often adulterated. Carpathian turpentine, or Riga balsam, exudes from the extremities of the young twigs of *P. amba*, to which flasks are suspended; it is a white, thin liquid, with an odor like that of juniper, and is employed as a medicine. Hungarian turpentine or balsam is obtained in the same manner from *P. pumilio*. The Riga and Hungarian balsams are but rarely brought to the United States. The dammara turpentine, which is employed in ship building and for a great variety of other purposes in the East Indies, soon concretes into a very hard resin. The turpentine of the *Dombeya excelsa* is a glutinous, milky-looking fluid, with a strong odor and taste.

TURPIN, TULPIN, or TILPIN, archbishop of Rheims, a friend and companion of Charlemagne. He was originally a Benedictine monk of the convent of St. Denis, but about 753 was made archbishop, and is said to have died about the beginning of the 9th century. His celebrity is due to the fact that his name is referred to a Latin chronicle, which relates the expedition of Charlemagne against the Saracens of Spain and the fight of Roncesvalles. It is uncertain whether the real author's name was Turpin, or whether it was a forgery. The work is, however, among the earliest productions relating to the events of Charlemagne's reign, and from it the tales of chivalry of the middle ages were largely taken. It was translated from Latin into French in 1206 by a clerk of Renaud, count of Boulogne. The original was first printed in the collection of Schardius fol., Frankfurt-on-the-Main, 1566).

TURQUOISE, a precious stone, colored by oxide of iron and oxide of copper, of the following composition: phosphoric acid, 30.9; alumina, 44.5; water, 19. It does not crystallize, has a waxy lustre, and varies in color from

blue to green. Hardness 6, or like feldspar; specific gravity 2.6 to 2.83. Nearly all the turquoises used in jewelry come from mines in Khorassan, about 40 m. W. of Nishapoor, which are crown property, and in 1821 yielded a revenue of about \$13,500. The gems are found in nodules and crusts in a porphyritic rock. The chief seat of the turquoise trade is at Meshed, where most of them are cut. The finest are generally reserved by the shah of Persia for his own use; the next in quality go to India, and those rather inferior to Persia, Turkey, and Russia. The imperfect ones, with white specks, are principally bought by the Arabs, who use them as amulets, generally setting them in rings of plated tin. A turquoise 2 inches long, said to have been a talisman belonging to Nadir Shah, and with a verse of the Koran engraved on it, is in the possession of a jeweller of Moscow, who values it at \$3,800. In the exhibition of 1851 was a collection of more than 200 turquoises obtained in 1849 by Major Macdonald from new localities in the mountains of Arabia Petraea, where they occur in nodules in a reddish sandstone. They differ in their shade of blue from the Persian stones, but agree with those found in Abyssinia by M. d'Héricourt. Common varieties are found in Saxony and Silesia; and there is a turquoise quarry in New Mexico. (See *CHALONNIER*.) The turquoise is much esteemed as a gem, particularly in Persia and Russia. Many magical properties have at various times been supposed to belong to it, and an old superstition, not yet quite extinct even in Europe, holds that it loses its color during the illness of its possessor, and regains it with his convalescence. The so called "occidental" or "bone" turquoise is only fossil bone colored by oxide of copper or phosphate of iron. It is brought from Siberia and France, but is not worth more than one fourth as much as the real stone. It may be distinguished by being internally foliated and streaked, and by not taking so high a polish. The turquoise is said to be now imitated in so perfect a manner as to be with great difficulty distinguished from the genuine, which is however harder.

TÜRR, ISTVÁN, a Hungarian general, born in Baja, in the county of Bács, about 1815. He volunteered in the Austrian army, became a sergeant major in the regiment of the archduke Francis Charles, served through the first Italian campaign in 1848, and was promoted to be sub-lieutenant. In Jan. 1849, he deserted to the revolutionists, and was commissioned by King Charles Albert to raise a Hungarian legion, which he commanded at the disastrous battle of Novara. After that defeat he withdrew to the grand duchy of Baden, and was there made a colonel in the revolutionary army. Escaping to England on the suppression of the insurrection, he entered the British service at the outbreak of the Russian war, received a commission in the Anglo-Turkish legion, and in 1855 was sent by the government to the Crimea to purchase horses for the army. Ar-

living at Bucharest, he found that place occupied by the Austrian regiment from which he had deserted in 1849; and although wearing the British uniform, he was arrested, sent to Hermannstadt, and condemned to death by a council of war. Liberated after some difficulty by the intervention of the English government, he returned to Turkey in 1856, and was preparing for an expedition into the Caucasus when a severe attack of hæmorrhage obliged him to retire from active service. On the commencement of the Italian war of 1859 he joined Garibaldi, and at the head of a battalion of the *cacciatori delle Alpi* distinguished himself in the engagements of Varese and Castel-Nedolo, receiving in the latter a severe wound in the arm. Though not entirely recovered, he took part in the expedition to Sicily in May, 1860, as aid to Garibaldi, was engaged in all the chief movements of the campaign, was wounded again at the taking of Palermo, displayed great bravery at Melazzo, commanded a division before Messina, and accompanied his chief to the mainland. He had an important share in the organization of the South-Italian army, and was one of the principal authors of the annexation of Naples to the kingdom of Italy. In 1861 he married Mlle. Wyse-Bonaparte, a granddaughter of Lucien Bonaparte. He is now (May, 1862) general of division in the Italian regular army.

TURRETIN, FRANÇOIS, a Swiss theologian, born in Geneva, Oct. 17, 1628, died there in 1687. He visited Holland and France in his youth, studied under Spanheim, Morus, and Diodati, and on his return in 1647 was ordained pastor at Geneva. In 1650 he removed to Leyden, but in 1658 was recalled to Geneva to become professor of theology. He published *Institutiones Theologiæ Elencticæ* (Geneva, 1679-'85), a work still regarded as one of the clearest and most satisfactory statements of the Calvinistic doctrines. His complete works were published at Geneva in 1688 in 4 vols. 4to.—JEAN ALPHONSE, son of the preceding, born in Geneva in 1671, died there, May 1, 1737, became professor of ecclesiastical history at Geneva in 1705, and published *Écrits sur la vérité de la religion Judæique et de la religion Chrétienne* (5 vols. 8vo.), an abridgment of ecclesiastical history, &c.

TURTLE, the name popularly applied to the marine chelonian reptiles, equivalent to the sub-order *chelonii* (Oppel), including the families *ephargididae* and *chelonoidae*; in these the dermal ossification is imperfect, and the limbs preserve through life the fingers undivided, as in the embryos of the higher families of the sub-order *amydæ* or tortoises. For the characters of the order see TESTUDINATA. The word turtle in Saxon meant turtle dove, a bird and not a reptile; and the English word had the same signification until the discovery of America, when sailors gave the name of turtle or turkle to the marine chelonians of the West Indies. As distinguished from the *amydæ* (see

TORTOISE), the turtles have the limbs converted into large, flattened, fin-like organs, the feet completely concealed by a common skin, the anterior pair always considerably longer than the posterior, and both frequently furnished with one or two nails on the outer margin, sometimes disappearing with age; the body is flattened to facilitate their progress through the water; swimming is performed almost entirely by the anterior limbs, the posterior moving independently and used chiefly to balance the body and guide its course; the anterior are raised and depressed together very much like wings, and have a free sweep up and down and forward and backward; on land they move slowly and awkwardly by means of the front limbs, projecting them forward and dragging the body up to them, assisted greatly by the nails; the bulk of the body is forward, where are the principal muscular masses; the humerus is very short, the forearm longer, and the hand longest; the humerus reaches forward and the rest of the limb backward, while in birds the former is directed backward, the forearm forward, and the hand again backward, the main surface of the wings being between the last two; the pelvis and hind legs are small. The head and limbs cannot be retracted under the shield as in the tortoises, and the plastron is less perfectly ossified and connected with the carapace; the ribs are narrowed toward the end, and the spaces between them at this point and the bony plates of the plastron are separated by intervals filled up by cartilage; the head is flattened above, protected by large plates; the jaws are strong and firmly articulated, horny, very sharp and beak-like, and the eyes large and prominent; the head is so placed on the neck as to allow the nostrils to be easily raised above the surface for respiratory purposes, their openings being closed by a fleshy valve. Much sea water is swallowed with their food, and when the former is of necessity regurgitated the latter is retained by the numerous horny processes, pointing backward, with which the oesophagus is furnished. The very young are longer in proportion to their width, and grow gradually broader. Though lower than the tortoises, the turtles exhibit features resembling those of birds in the form of the anterior limbs, the mode of locomotion, the preponderance of the fore part of the body, bill-like jaws, and overlapping epidermic appendages. All are marine, excellent swimmers, and rarely approach the shore except to deposit their eggs; some feed entirely on sea weeds, but a few eat mollusks, crustaceans, and other aquatic animals; they are generally timid, and make but little resistance, though they are more bold and regardless of danger in the pairing season. The flesh of the herbivorous species is a delicious and wholesome food, and much sought after by epicures, while that of the carnivorous is disagreeable if not positively injurious; the callipee, or under part of the breast and abdo-

nen, is considered the choicest part; the liver and fat are also much esteemed. They come on shore toward the end of spring to lay their eggs on the sandy beaches above high water mark; they generally select desert islands or keys, and a still moonlight night; they dig a trench in the sand by their hind feet about 14 feet deep, and deposit therein about 100 eggs at each of 3 sittings, with an interval of 2 or 3 weeks between them; the eggs are lightly covered with sand, and left to be hatched by the heat of the sun; if undisturbed, they return to the same shore year after year. They are caught on the shore, being turned on their backs, a position from which they cannot escape owing to the flatness and width of the shell; they are harpooned and taken in nets in the water, and in the Indian seas are captured by means of the *remora*. (See *SUCKING FISH*.)—In the *chelonioides* the body is widest about midway, and the vertebral column descends constantly and gently to the tail; the houlders and hind limbs are better protected than in the other family; the shield is more or less heart-shaped, with the posterior angle not prolonged into a point extending far over the tail; all the genera are represented on the coast of the United States, and are far less rapid swimmers than the *sphargididae*. The latter family has only the single genus *sphargis* (Merrem), showing well the inequality of the natural groups called families; the body is more conical than in the other turtles, the carapace leaving the hind legs as well as the houlders and neck much exposed from its great contraction behind and in front; the lower parts are equally unprotected by the plastron, this with the carapace forming little more than a wide girdle around the thorax and abdomen; the skeleton is light, the paddles large and free, and every thing seems arranged for rapid and long continued voyages.—The green turtle (*Chelonia mydas*, Schw.), sometimes attaining a length of 5 or 6 feet and a weight of 100 or 600 lbs., received its name from the color of the delicate fat which enriches the soup and other dishes of a course of turtle. It has a short and rounded snout, and jaws acting like straight-edged shears cutting from behind forward, the upper slightly notched, the lower with a deeply serrated margin and a hook in front; shell smooth, with 13 plates, 5 vertebral and 8 lateral, not imbricated, slightly notched and serrated behind, and with 25 marginal plates; anterior limbs rounded at shoulder, covered with a tough skin and a few small plates; forearm and hand with large plates on the anterior border, smaller ones elsewhere, and an extensible fold of skin along the posterior margin; hind limbs short and flattened, covered with small plates and a larger fold of skin on the margin; a single nail to each limb; the shell is light brown, with darker lines and blotches, and sometimes with a greenish tinge; below pale yellowish white. It is abundant in the tropical waters of America, whence great

numbers are carried alive to the northern states and to Europe; the West Indies are its head-quarters, whence it wanders to the gulf of Mexico and the coasts of Guiana and Brazil; it is rarely found above lat. 34° N. on the Atlantic coast, and never on the shores of Europe; the Tortugas islands are a favorite resort. It browses on the turtle grass (*zostera marina*), eating the succulent part nearest the root, the rest rising to the surface and disclosing the feeding grounds to the practised eye; in confinement it will eat and grow fat upon purslane (*portulaca oleracea*); numbers are kept for a long time in pens or crawls filled at every tide. It is often seen many hundred miles from land, and is easily taken when asleep on the surface; its capture gives employment to many and food to thousands in the West Indies; for an interesting account of some other methods of taking them, and of the manner in which the eggs are laid, the reader is referred to Audubon's "Ornithological Biography," vol. ii. pp. 370-76 (Boston, 1835); during the actual laying of the eggs nothing can disturb their labors; they are hatched in 8 or 9 weeks. The flesh is exceedingly delicate, and, when not rendered indigestible by the ingenuity of cooks, is wholesome in moderate quantities; the eggs of this and of all the species are also considered a delicacy. In the young the carapace is relatively the narrowest, and the colors of the adults vary much. The *C. virgata* (Schw.), mottled with brown and greenish, and with a more elevated and arched back, is found on the California coast and on the Pacific; the common species is said also to occur at the Cape Verd islands and on the Atlantic coast of Africa. As in all the species, the eggs are dropped one by one, and disposed in regular layers, during a period of about 20 minutes; they are round, 2 to 3 inches in diameter, with the external membrane flexible, very white, and containing a considerable quantity of calcareous matter; the shell of the young is soft, and affords but little protection against birds of prey on land and predaceous fish and alligators in the water.—The loggerhead turtle (*thalasseochelys caerulea*, Fitz.) has the body very wide across the shoulders; the head very large and flat, with wide mouth, the upper jaw nearly straight, and the lower hooked; shell smooth, with a keel along the median line, and a crescentic notch in the posterior border; the plates are thin and flexible, 5 vertebral and 10 lateral, not imbricated, and the marginal plates 25; each limb has 2 nails, corresponding to the first 2 fingers; the color above is light brown, sometimes with an olive tinge and often bordered with dirty yellowish; and the shield, as in the other turtles, is frequently more or less covered with barnacles, serpulæ, and other parasites. It has an extensive range on the American coast of the Atlantic, from Virginia to Brazil, and probably on the shores of Europe and in the Mediterranean; it is more common than the green turtle, and grows to a large size, even to 15 or 16 cwt.;

It is voracious, feeding principally on mollusks, being able to crush with its powerful jaws the strongest conch and helmet shells (*cassia*); the flesh of the young is sometimes eaten, but that of the old is rank and tough; the scales are of little value, and even the eggs have a musky flavor; it is taken only for the considerable quantity of excellent burning oil which it furnishes. The *T. olivacea* (Ag.) is found in the Pacific.—The hawk's bill or imbricated turtle (*eretmochelys imbricata*, Fitz.) has a low and rather wide head, a long and narrow mouth, the upper jaw prolonged and hooked like the beak of a hawk, the lower jaw with a smaller hook, and both with serrated margins; the shell is slightly keeled, flattened and serrated behind, with 5 vertebral and 8 lateral plates strongly imbricated or overlapping like the scales of a fish; the plastron has 2 keels, more or less worn off by age; there are 2 nails to each limb; anterior limbs very long and wing-like; the head is protected by 14 scales; the tail is conical, not extending beyond the shell. The color is yellowish above, marbled with rich chestnut brown, and yellowish white below; in the young there is a black spot on the 4 posterior pairs of plates. It is found in the West Indies, the gulf of Mexico, on the coasts of Guiana and Brazil, and has even strayed to the Mediterranean; the *E. squamata* (Ag.) is found in the Pacific and Indian oceans, the best being taken about the Moluccas and New Guinea. The food consists of sea weeds, crabs, mollusks, and fishes; in confinement it is more fierce than the preceding two; it rarely grows more than 3 feet in length; its flesh is indifferent, and it is said unwholesome, though the eggs are good, and the species is sought after only for its beautiful horny plates, which constitute the tortoise shell of commerce. The plates are softened by warm water, and by means of this and strong compression can be bent into any shape, even the parings being thus agglutinated and turned to account; they are not considered of value unless from an animal weighing at least 160 lbs., as otherwise they are too thin; 15 lbs. of shell from a single one is a large amount, and yet in animals of the same size the imbricated would be worth when taken 10 times as much as the green turtle. Singapore and Canton are the great marts for tortoise shell. Its ornamental uses for boxes, combs, furniture, and fancy articles are well known; it was consumed in large quantities in ancient Rome, even the door posts of the rich being inlaid with it; the carapace was used as a cradle and a bath tub for children, and as a shield for warriors.—The leathery or trunk turtle (*ephargis coriacea*, Merr.) is so named from having the carapace overlaid by a leathery skin instead of horny plates, smooth in the adult, but tuberculated in the young, and with 7 longitudinal ridges; the head is large, narrowed in front of eyes, with small and circular nostrils, and large eyes with lids opening nearly vertically; jaws very strong
